Mosaie. Mosaic work (Lat. opus mosaeum) consists of small pieces of diversely coloured marble, glass, or other substances set together so as to produce a geometrical or artistic design. Mosaics are principally used for ornamental doors and pavements, and for the permanent artistic decoration of the interior of churches and other public buildings. The art is of ancient origin, as may be inferred from the book of Esther we may infer that it was practised in the days of Ahaseurus; but among the Romans it was very common, for scarcely have the remains of any ancient Roman villa been discovered without finding in it a mosaic pavement. These ancient pavements being composed of small tesserae or dice of coloured marble, and rarely also of glass, are known as tessellated mosaics. The pieces used consist of irregular cubes varying from a quarter to half an inch in size, which are laid in a cement matrix set over a prepared concrete foundation. The designs, pictorial or otherwise, are produced by selecting and setting together, in proper position and relation, tesserae of the required colour and size. The most famous tessellated pavements are those that obtained from Hadrian's villa at Tivoli, preserved in the Capitoline Museum at Rome, and known as 'Pliny's pigeons' from the subject it depicts. Under the Byzantine empire mosaic became a chief form of Christian art, employed for decorating the walls of churches with figures of the Saviour, apostles, saints, &c., and the remains of such Byzantine art form a link of great importance between classical and medieval periods. The art was revived in Italy about the beginning of the 13th century, when it was employed with great effect for the decoration of churches; and since that time it has remained, with many fluctuations, a distinctively Italian pursuit. Modern mosaics are also made in Russia, forming a department of the imperial glass manufactory at St Peters burg; and such pavements are often seen during the summer.

The cubes of opaque glass for mosaic pictures, technically called smalts (Ital. smalto), are of all possible varieties of colour, as many as 23,000 shades being prepared. With these the finest gradations in tone may be produced, and copies of any painting may be made, but mosaics of real artistic significance are simple in composition, and broad and sober in treatment. Italian mosaics are of two distinct classes—Florentine and Roman, the former being composed of pieces of stones or shells of natural colours shaped and inlaid in marble slabs according to the design to be produced; but it is limited in its application chiefly to floral scrolls and Arabesque designs. This variety of mosaic is extensively produced in India, having been there introduced by the Frenchman Austin de Bordeaux in the beginning of the 19th century. The Mahal at Agra, whence it is distinguished as Agra work. Roman mosaic is made up of the small cubes above mentioned, and, while the larger wall decorations are composed of pieces which may be as large as inch in size and upwards, small mosaics are composed of pieces of glass, these being used by jewellers for the ornamentation of bracelets, small boxes, and miscellaneous bijoux. Mosaic pavements are extensively made of small cubes or tesserae of coloured marbles, and baked clay or terra-cotta similar to the ancient Roman tessellated pavements.

See Thomas Morgan, Roman-Brithish Mosaic Pavements (1856); Parker's Church Decorations and Mosaic Pictures [Archcol. of Rome, vol. xi. 1876]; and Gersbach, La Mosaique (1883).

MOSASaurus, a huge fossil reptile, belonging to the remarkable group of Pythonomorphs or 'sea-serpents,' which suggest both lizards and snakes. The remains of three species have been disinterred from Cretaceous strata. They were aquatic animals, furnished with paddles, and are estimated to have attained a length of as much as 75 feet (see REPTILES).

Mosaylima, or MOSELLEMA ('Little Mohamet'), one of the three main tanns of Mohammed belonged to the clan Dûl, a division of the tribe of the Beni Hanîfah, of Yamâmâ in Nejd. The traditions about his life and age are extremely contradictory and legendary. It appears, however, tolerably certain that he had risen to some eminence in his tribe, probably as a diges-teacher only at first, before Mohammed assumed his prophetic office. It was in the ninth year of the Hegira that Mosaylima, at the head of an embassy sent by his tribe, appeared before Mohammed, in order to settle certain points of dispute. Shiekh, but this event Mosaylima openly professed himself to be a prophet as well as Mohammed. The latter sent a messenger to him, as soon as he heard of this, to request him to reiterate publicly his profession of Islam. Mosaylima's answer to this request was, 'Mohammed should share his power with him.' From this event Mosaylima, the Apostle of God,' he is said to have written, 'to Mohammed, the Apostle of God. Now let the earth be half mine, and half thine.' Mohammed replied: 'From Mohammed, the Apostle of God, to Mosaylima, the Apostle of God, to God.' He gives the same for inheritance unto such of his servants as He pleases, and the happy issue shall attend those who fear Him.' Yet notwithstanding these testimonies, of probably late dates, it seems, on the other hand, perfectly certain that Mohammed made Mosaylima one of his chief adherents, and that he by this means bought Mosaylima's open allegiance during his lifetime. It was not a question of dogmas, though they each had special revelations, but a question of supremacy which was thus settled amicably.

After Mohammed's death, in the 11th year of the Hegira, it at last came to an open breach between the two rival powers. Abu Bekr, the calif, sent Khalid, 'the Sword of the Faith,' with a number of choice troops to conquer and an able commander, to quell. Mosaylima awaited the enemy at Rowlah, a village in the Wadi Hanîfah. So formidable indeed was Mosaylima's force that Khalid is said to have hesitated for a whole day and night. On the second morning, however, he advanced, and, in a battle which lasted until the evening, contrived, with fearful losses of his own, to gain the victory, in which Mosaylima fell, and his success was practically stamped out. It is extremely difficult to come to any clear notion of Mosaylima's real doctrines, as all the accounts that have survived of them come from victorious adversaries. See Sir W. Muir, Annals of the Early Caliphate (1883).

Moscheles, IGNAZ, pianist and musical composer, born at Prague, 30th May 1794, of Jewish parents, was admitted to the SIS and cultivated music. He began to play music at an early age, and was a pupil of Aloysia, the Moscheles rank high amongst modern writers for the pianoforte. He also edited, in English,
MOSCHUS

Schindler's Life of Beethoven (1841). See The Life by his wife (Eng. trans. 1873), and his Correspondence with Mendelssohn (Eng. trans. 1883).

MOSCHUS, Greek bucolic poet, usually designated of Syracuse in Sicily; he flourished circa 150 B.C., and wrote in a style of almost painfully finished elegance an epitaph on Lilio, a couple of short epics, and minor poems. His works are generally printed along with those of Theocritus and Lilio; and there is a fine prose translation of the three, with an introduction, by Andrew Lang (1889).

MOSCOW, formerly the capital of Russia, and still venerated as such by the Russian peasantry, stands on the little river Moskwa, a sub-tributary of the Volga, 403 miles by rail S.E. of St. Petersburg, 768 ENE. of Warsaw, and 967 NNE. of Odessa.

The city, a rude rhomboid in shape, measures 7 miles by 9 along its diameters and covers some 40 sq. m. of area. Its centre is the enclosure called the Kremlin or Kremlin ('Citadel'), which is surrounded by walls, crowned by eighteen towers and pierced by five gates. This enclosure is the most sacred spot in all the vast Russian empire. The stranger usually enters it on entering its Saviour gate (1491), must doff his cap to the holy icon of the Saviour that surmounts it. The most notable of the religious buildings inside the Kremlin are the cathedral of the Assumption, built originally in 1326 and rebuilt in 1475-79; its interior is ornamented with mosaic and jewelled ornaments, adorned with venerated pictures, and sanctified by numerous relics of saints; within its walls the early czars and all the Russian metropolitans and patriarchs have been consecrated, and the metropolitanos buried. The cathedral of the Archangel was originally built in 1333, but restored in 1505; here were buried the Russian czars down to Ivan Alexievitch, brother of Peter the Great. The cathedral of the Annunciation (1489; rebuilt 1554) was formerly the private chapel of the czars; it is adorned with some remarkable paintings by Rubble (1405). There are numerous churches of minor rank, and several monasteries; in the Voznesenski monastery (1393) the czarinas and female relatives of the czars are buried.

In 1600 Boris-Godunoff built in the Kremlin the Ivan Veliki tower, 250 feet high, the summit of which commands a magnificent view of Moscow, with her gilded cupolas and fantastic towers, her half Asiatic, half European architecture. Close by, at its foot, stands the gigantic bell, Czar Kolokol ('king of bells'; see BELL). The more important secular buildings within this sanctuary of Moscow are the imperial palace (1490; the palace built in the reign of Ivan III.; the new palace Oruslenaya, which serves as a museum of the most valuable Russian antiquities; the palace of the patriarchs, with archeological treasures and 1500 rare Russian and Greek MSS.; the arsenal (1701-36), before which is the trophy of 1812, a pile of 800 or 900 French cannon; and the Hall of the Synod, with a valuable library and ecclesiastical collections.

Outside the Kremlin the chief objects of interest are the colossal 'Temple of the Saviours' (1838-81), a building suggestive of a cathedral; the cathedral of St. Basil (1554), a 'nightmare in stone', with fantastic towers; the gigantic bazaar (Gostinii Dvor); the historical museum; the library (10,000 vols. of old printed books and 600 MSS.) of the synod and its typographical museum; the university (1755), with its museums and a library of 170,000 vols.—it is frequented by 3350 students; the public museum (1861), containing a library of 300,000 vols. and 5000 MSS., a first-rate ethnological museum, a gallery of pictures, and scientific collections; the Golitzyan Museum (1800), with 50,000 vols. and a collection of paintings; an observatory; a large foundling hospital (1764); and numerous monasteries and special educational institutions.

Moscow is celebrated for its excellent scientific societies. The suburbs of the city are thickly sprinkled with parks, palaces, and monasteries, some of the first and last being of great historic significance.

Next to St. Petersburg, Moscow is the busiest industrial city in the empire, manufacturing cotton and woollen goods, silks, leather, tobacco, candles, metallic articles, machinery, paper, chemicals, bricks, carriages, pottery, and watches, all on an extensive scale. But the city occupies an even higher position as a commercial mart. Situated nearly in the centre of European Russia, midway between the Baltic, the Black Sea, and the Caspian, it is one of the principal meeting-places of the streams of Asiatic and European commerce. In the 14th, and more especially the 15th century, it was of even greater importance than it is to-day as a commercial mart. An enormous trade is done in grain, collected from the provinces and exported through the Baltic ports; in timber, from the northern governments; in furs, hides, tallow, and cattle; in the mineral products of the Urals region; in tea, sugar, and other groceries; in cotton, silk, and woollen goods, and in all the various manufactured wares of Russia. The Moscow customs office levies annually £6,000,000 to £7,000,000 on merchandise entering the city bounds. Pop. (1864) 305,000; (1891) 822,397, nearly all Great Russians of the Orthodox Greek Church. As a general rule the temperature ranges from a winter mean of 14° F. to a summer mean of 67°, the annual mean being 40°.

Previous to its settlement by Great Russians in the 12th century, the site had been occupied by Finnish races. The young state was greatly imperilled in its first years by the Mongols, who sacked the town in 1237 and 1290. But by the beginning of the 14th century its princes had secured their position, and began to make conquests and annexations on all sides. In 1325 the metropolitan of central Russia moved his seat to Moscow; a few years later the principality of

Cathedral of St. Basil, Moscow.
Moses, B. Michael (1704–83), was an enameller and gold-chaser, the first keeper of the Royal Academy; and she herself died Mrs Lloyd, at a great age in 1819.

Moses (Heb. מֹשֶה; LXX, and Vulgate מֹּסֵס), the great lawgiver and judge, under whose leadership Israel first began to be a nation. The whole subsequent course of Hebrew history and literature bears witness to the greatness of his fame and influence. In the details of his life preserved in that literature, there is much uncertainty, and in many respects he is not, as a whole, very full or satisfying. This was felt to be the case even when it was believed that the so-called ‘Books of Moses’ were written by him, and, therefore, so far autobiographical; and now it is thus he is described (q.v.), or rather Hex- tuch, is held not to have taken the present form till at least 800 years after his death, and the historical traditions which it embodies are seen to be of various dates and to represent various phases of growth, the outline of his life and character has become dimmer than ever. He

still remains, nevertheless, a great historical figure. If we adopt the now very generally accepted belief that Moses lived, or perhaps rather was the Pharaoh of the Exoduses (see EGYPT, Vol. IV, p. 240), Moses was born in the first half of the 14th century B.C. At the time of his birth the ‘children of Israel’ (The Israelites) were a pastoral people who had long dwelt on the eastern fringes of the Nile delta, and perhaps it was combined with an Arab name in the Arabian desert. His name— for which a Hebrew interpretation (‘drawn’; the verb is the same as in Psalms, xviii. 16) is offered in Exodus, ii. 10—is now generally supposed to be really of Egyptian origin (though perhaps in more than one sense), and possibly connected with the Nile delta. It is not merely characteristic of the whole of Egypt and Israel in the movement for civil and religious freedom which led to the Exodus. Thenceforward the scenes of his activity were principally Sinai, the ‘Olympus of the Hebrew peoples,’ En-Mishpat or Kadesi (Gen. xiv. 7), a locality of which the site is not known. The Exodus was probably the migration of the Israelites from Moab to the east of Jordan. The greater part of the time was no doubt passed at Kadesh, which seems to have long been the national headquarters. Here his energy and force of character, combined with a conciliatory meekness (Numb. xii. 2), has been expressed, and perhaps also, in a sense, the beginnings of the national organisation on an enduring basis. At the foundation of the commonwealth as outlined by him lie the theocratic idea, and the faith which had for its formula ‘Jehovah is the God of Israel, and Israel is the people of Jehovah.’ Although there the name Jehovah was not unknown in pre-Mosaic times, it was not until now that it became a national watchword. Among the religious institutions possessed by Israel were some which their patriotism, with them in their early migrations from Canaan, and others that had been more recently acquired in Egypt. To the former class belonged the fundamental institution of sacrifice, and also, possibly, that of the Sabbath; on the other hand it seems probable that the idea of a connected sanctuary and a sacred mark and of the centralised administration had the later origin. The practices resting on these Moses, as a ‘prophet,’ extended, regulated, and reformed. It was as a member of the priestly caste (he belonged to the tribe of Levi) that he was the sanctuary and oracle of Jehovah at the ‘Well of Judgment’ (En-Mishpat) he exercised the functions of law-maker and judge, and so laid the foundations of that ‘Torah’—i.e., instruction or ‘law’—which, handed down by oral tradition and enriched by over-broadening precepts, ultimately passed into writing in more than one form as the Mosaic legislation. It does not appear that writing was much used in these early days; and most modern critics are agreed that the historical portions, as well as almost all the legislative documents, of the Pentateuch belong to a much later time. The poetic element in the works attributed to Moses—the so-called ‘Song of Moses’ (Deut. xxxii.) and Psalm xc.—also give internal evidence of more recent authorship.

After the close of the Old Testament canon Jewish tradition still busied itself about the story of Moses; some of its later additions have been preserved in the writings of Philo and Josephus (cf. Acts, vii. 22), and many more in the Palestinian Targums on Exodus. For a good popular study of the life of Moses, see Rawlinson’s Moses: his Life and Times (2d ed. 1880); the point of view is represented in Wellhausen’s History of Israel (1885), pp. 429-440; Reuss’s Geschichte des Alten Testaments (2d ed. 1890); Renan’s Histoire du Peuple
general this is also the case generally said a day in week in the mosque by the whole congregation on Fridays and certain other days together with some additional prayers and at times a sermon is supplemented to the service. It is not customary for women to visit the mosques, and if they do, they are separated from the male worshipers. In entering the mosque, the Moslem takes off his shoes, performs the necessary ablutions, and finishes by putting on his shoes and any arms he may have with him upon the matting before him. The chief officer of a mosque is the nazir, under whom are two imams, a kind of religious officials, in no way to be compared with what we understand by a clergyman of a creed, but who performs a certain number of religious rites, and, being very badly remunerated, generally has to find some other occupation besides. There are further many persons attached to a mosque in a lower capacity, as muezzins (q.v.), door-keepers, &c., all of whom are paid from the funds of the mosque itself—generally derived from lands. With many of the larger mosques there are schools, academies (medressas), and hospitals connected, and public kitchens, in which food is prepared for the poor.

Mosquito (dim. of Span. mosca, ‘a fly’). The name applied to various troublesome gnats, for the most part belonging to the genus Culex, though sometimes members of the adjacent family Simulidae. They are very widely distributed, especially in tropical countries, but also in the far north, as in Arctic America, Lapland, and Siberia. The Mosquito is justifiably applied are not yet known with sufficient precision. Yet the entomologists catalogued 150 species of Culex alone, of which 35 occur in Europe, and most of these bite sorely enough to be ranked as mosquitoes. In hot summers the cry is sometimes heard that mosquitoes have appeared in Britain from the Continent or even from America. Importations do not disturb; but the fact is that mosquitoes are always with us under the name of gnats. In hot weather they often appear in great swarms, especially in low countries, and the prevalent measure to combat them is the application of various swarms which they feed upon. The possession of the British Isles is attributed to the British troops, who have successfully invaded the Continent and driven the Mosquito to the Continent or even from America. The matter is therefore not definite, but the fact is that mosquitoes are always with us under the name of gnats.

Mosque, a Mohammedan house of prayer. The word is derived, through the Italian mosche, from the Arabic masjid, ‘a place of prayer.’ The form of the oldest mosques is evidently from that of the Christian basilica (see ARABIAN ARCHITECTURE). The original forms became, however, entirely obliterated in the progress of Mohammedan architecture, and mosques, with their arcaded courts, gateways, domes, minarets, and minarets, are the most characteristic edifices of Saracenic art. Wherever the Mohammedan faith prevailed, from Spain to India, beautiful examples of these buildings exist. They vary considerably in style in different countries, the Saracens generally borrowing much from the architecture of the various countries which they adopted their faith. In India the mosques have many features in common with the temples of the Jains (see the section on architecture in INDIA, and the illustration at AGRA), while in Turkey they resemble the Byzantine architecture of Constantinople. Everywhere the dome is one of the leading and most beautiful features of the mosques, which commonly consist of porticoes surrounding an open square, in the centre of which is a tank or fountain for ablution. Arabesque and geometrical designs of the Koran, inserted upon the walls, which are generally whitewashed, and never bear any device representing a living thing, are the only ornaments of the interior. The floor is generally covered with mats or carpets; there are no seats. In the south-east is a kind of pulpit, or mimbar, for the Imam, and in the direction in which Mecca lies (the Kiblah), there is a niche (mihrab) towards which the faithful are required to look when they pray. Opposite the pulpit there is generally a platform (dikkeb), surrounded by a parapet, with a desk bearing the Koran, from which portions are read to the congregation. The five daily prayers, which are generally said at home on week-days, are said in the mosque by the whole congregation on Fridays and certain other days together with some additional prayers, and at times a sermon is supplemented to the service. It is not customary for women to visit the mosques, and if they do, they are separated from the male worshipers. In entering the mosque, the Moslem takes off his shoes, performs the necessary ablutions, and finishes by putting on his shoes and any arms he may have with him upon the matting before him. The chief officer of a mosque is the nazir, under whom are two imams, a kind of religious officials, in no way to be compared with what we understand by a clergyman of a creed, but who performs a certain number of religious rites, and, being very badly remunerated, generally has to find some other occupation besides. There are further many persons attached to a mosque in a lower capacity, as muezzins (q.v.), door-keepers, &c., all of whom are paid from the funds of the mosque itself—generally derived from lands. With many of the larger mosques there are schools, academies (medressas), and hospitals connected, and public kitchens, in which food is prepared for the poor.

Mosquito Coast, or Mosquitia, formerly an independent estate in the province of Honduras, lies on the east side of Nicaragua (q.v.), to which it has belonged since 1850. The coast-lands are low and swampy, but the interior rises into mountains, and is healthy. The characteristic products of the West Indies are grown. The inhabitants are a mixture of the Indian and negro blood, and the number about 15,000. The chief town is Bluefields (pop. 500). The Mosquito Coast was discovered in 1502 by Columbus, and, though never conquered, was claimed by Spain. During the 17th century it was the rendezvous of the Buccaneers (q.v.), and was subjected to Britain in 1655, who only abandoned it in 1850.
Mossamedes, a seaport on Little Fish Bay, in Angola, the Portuguese territory on the West Coast of Africa. Pop. 2000.

**Mosses (Musci).** The mosses are a class of small flowerless plants, important in the economic, nature, and of great interest in their life-history. They are found in all climates, but are most abundant in temperate regions and in damp places. They are included with the Liverworts in the division Musci, which is sharply separated from the higher division of Vascular Cryptogams (Ferns, &c.) by the absence of vessels; while the lower members of the group consist of a mere flat thallus, and are thus related to the Thallophytes. This, with other characters, indicates that the Musci form an independent branch of the tree of evolution, and are not an intermediate type.

The uses of mosses in medicine and the arts are few and unimportant, but in mountain-regions the thick felt of moss and deep beds of peat soak up the rain, and so prevent floods from sudden storms, and in dry weather supply the streams through weeks of drought. With favouring surroundings the life of a moss-plant seems to be endless; the mosses (Sphagnum) we see growing to-day in a bog are the tips of plants which began life perhaps thousands of years ago, and which have formed a great bed of peat, which may be 20 feet thick. This social habit of moss is peculiar. In some species cushions of marvellous regularity are formed; it enables individual plants to stand erect, and is of great importance in the process of fertilisation. The capsules of many mosses must be familiar to every one as small warts at the ends of their hair-like stalks, which rise in great numbers from a moss-cushion. These contain the spores, from each of which when sown there grows in a few days a tiny thread-like plant, the protonema. Buds of young moss-plants soon appear on this, and then, as a rule, thread-plant dies. A moss-plant consists of a stem with leaves and roots. The roots will grow out from any part of the plant that is kept dark and damp; they are very like the protonema, indeed buds of new plants may arise on them. Even from a detached leaf root and new plants will grow; this is a sign of the simple nature of the tissues. By their branching habit, and by the death of the older parts, which leave the branches as separate plants, and in many species by the growth of special buds which are easily separated from the parent, mosses are rapidly pro-

### Diagram of the Life-history of a Moss:

---

**MOSTAGANEM**

Mostagamen, a town of Algeria, on the coast, 45 miles N.E. of Oran, manufactures pottery and has corn-mills and tanneries. Pop. (1868) 12,305, more than half of which being Berbers. It is a place of 40,000 inhabitants in the 16th century; and has again grown up from its decayed state since the French took possession in 1833.
Mostar, the chief town of Herzegovina, on the Narenta, about 35 miles from the Adriatic, connected by railway with the port of Medjedov, and rid Sarajevo with Budapest. It takes its name ("old bridge") from a 16th-century bridge of one arch, 93 feet in span, has numerous mosques, and is the seat of a Roman Catholic and a Greek bishop. Wine is produced, and swords and tobacco manufactures. Pop. 12,633.

Mosul, a decayed town of Asiatic Turkey, in the province of Al-Jezirah (ancient Mesopotamia), is situated on the right bank of the Tigris, opposite the ruins of ancient Nineveh (q.v.), 200 miles up the river from Baghdad. It is partly surrounded by crumbling walls. During the middle ages it was a very prosperous city, with much industry—muslin takes name from this town; now its bazaars are filled with the manufactures of the West, and almost the only export is gall-nuts, from the Kurnish mountains. Mosul is formerly the metropolis of the Mesopotamian Christians (the Nestorians, the United Chaldeans, the Jacobites, &c.), and still contains many Catholic Christians. Pop. estimated at 30,000. The town, which existed in 636, enjoyed its greatest prosperity in the 9th century, and onwards, until the end of the fourth of the Mongols in the 12th. Then came the Seljukis; and they were followed by the Turks, and since then Mosul has steadily declined.

Motaillidae. See Wagtail.

Motaxilites, a 'heretical' Mohammedan sect, founded by Wa'il b. Ata in the 2d century after Mohammed. They denied predestination, and recoiled in man a power over his own actions.

Motehbull. See Folkmoot.

Motett, a name applied to two different forms of musical composition—(1) a sacred cantata, consisting of several unconnected movements, as a solo, trio, chorus, fugue, &c.; (2) a choral composition, generally also of a sacred character, beginning with an introduction in the form of a song, perhaps with figurative accompaniment; after which follow several fugue subjects, with their expositions, the whole ending either with the exposition of the last subject, a repetition of the introduction, or a special final subject. A motett differs from a double or triple fugue in that the subjects never appear simultaneously as in such pieces; they are introduced one after the other. In one form of the motett the successive phrases of an entire chorale are treated as so many fugal subjects.

Mother Carey's Chicken, a name (a corruption of Mater cara) familiarly given by sailors to the Stormy Petrel and other small oceanic species of Petrel. The name Mother Carey's Goose is, in like manner, given to the Great Black Petrel or Giganto Fulmar (Procellaria gigantea) of the Pacific Ocean (see articles on PETREL and Fulmar).

Mother of Pearl. See Pear.

Motherwell, a town of Lanarkshire, 12 miles SE. of Glasgow. Owing its rapid growth to the amazing extension of its mineral industries, it has a good water-supply (1877), municipal buildings (1887), a public park (1887), large iron and steel works, &c. Pop. (1841) 726; (1861) 2955; (1871) 6943; (1881) 12,904; (1891) 18,726.

Motherwell, William, a Scottish poet and educator, born in 18th October 1797, and educated in Edinburgh and at the grammar-school of Paisley, where, in his fifteenth year, he entered the office of the sheriff-clerk. At the age of twenty-one he was appointed sheriff-clerk depute of the county of Renfrew. In 1819 he published his first work, the Harp of Renfrew—shire, containing biographical notices of the poets of that district from the 16th to the 18th century. This work was but the prelude to one of far greater importance—his Minstrelsy, Ancient and Modern (1827). In 1828 he commenced the Paisley Magazine, in which some of his finest original pieces first saw the light, and in the same year accepted the editorship of the Paisley Advertiser, a Conservative journal. In 1830 he became editor of the Glasgow Courier. In 1832 he published a collection of his best poems, entitled Poems Narrative and Lyric. He died in Glasgow, November 1, 1835, at the early age of thirty-eight. Motherwell displays an astonishing variety and beauty of imagination, and a strong and beautiful, and strong imagination, great warmth and tenderness of feeling, and a thorough knowledge of the technique of a poet. His Jeannie Morison is unsurpassed for the mingled pathos and picturesque beauty of its reminiscences of boyish love; and the little piece beginning, 'My bed is like to rend, Willie,' has seldom been read without tears. An enlarged edition of his poetical remains, with a memoir, was published in London in 1849.

Motherwort (Leonurus cardinaceus), a plant of the natural order Labiatae, found about hedges and in waste places in Europe, and now abundantly naturalised in some parts of North America. It is not very common in Britain, and probably has been introduced. It is perennial, has a branched stem about 3 feet high, stalked leaves, the lower ones 3-lobed, and rounded whorls of reddish-white flowers. The plant was formerly in much use as a domestic pectoral medicine, but is now comparatively little employed. It has a strong, but not agreeable smell. Other species of the same genus are found in Europe and the north of Asia.

Moths, a sub-order of Lepidoptera insects, which in twilight and darkness take the place of the light-loving butterflies. Technically known as Heterocera, they are distinguished from the butterflies by their antennae, which are variable in form instead of being constantly club-tipped, and by the fact that the wings are usually expanded, and not elevated, when the insect is at rest. Like the parallel series of butterflies, the moths differ greatly from one another in size and colour, but the caterpillars, which are fed mostly on living plants, and in this connection are very familiar; others of these ravaging forms spin clothes, fun, and the like. Most of the latter belong to the family Tineidae, especially to the genus Tinea. They are the 'moths par excellence,' against whose ravages housewives carefully guard. Clothes should be kept perfectly dry, and the...
warrodes, chest, &c. containing them should have no cracks or crevices. Pieces of camphor, sprinkled pepper, and strongly odoriferous 'moth-powder' of some sort will help to keep the adult moths away; but when a host of larvae have possessed the garment it may be immersed in boiling water, carbolic acid, or even a solution of carbolic acid and ether. The only directly useful form is the Silk-moth (q.v.). There are separate articles on the Hawk Moth, Death's-head Moth, Gooseberry Caterpillar, &c.; see also BUTTERFLY, CATERPILLAR, INSECTS.

Motif, in a musical composition, means the principal subject on which the movement is constructed, and which, during the movement, is constantly implied by or to the other parts, either complete or modified. In elaborate and long compositions there are also secondary motifs.

Motion, Laws of. In developing the subject of Dynamics (q.v.) it is convenient to lay down in the form of postulates axioms or the fundamental principles on which the science is based. These axioms are generally referred to as the laws of motion. They rest ultimately, as they do in the axioms of geometry, on experience; and once the terms in which they are expressed are sufficiently understood, the laws themselves are admitted without further question. We owe to Newton what still remains the most serviceable, because the most indispensable part of the complete expression of these dynamical axioms. Newton's predecessors, particularly Galileo, had already formulated some of the fundamental principles of abstract dynamics; but in the Three Laws of Motion, which form the basis of the Principia, we have for the first time all the necessary and sufficient principles laid down in a manner easy to understand and easy to apply. These three laws are given both under DYNAMICS and under FORCE, and need not be reproduced here.

Newton's method of presenting his definitions and axioms has been the subject of much criticism. And doubtless a logician, confining his attention to the eight definitions of mass, momentum, inertia, force, acceleration, &c., and the three laws of motion, could easily discover fault with the arrangement. Everything, taking this preliminary essay of the Principia, with its masterly schola, as a whole, and bearing in mind that the aim is to establish a theory of dynamics that shall harmonise with the facts of experience, we shall find no difficulty in admitting the method as arranged. There is an absolutely no confusion of thought. The demands on our intellectual faith, whether explicitly stated or implicitly involved in other statements, are essentially rational. The treatment is luminous as it is profound. Attempts have been made to substitute a more logical procedure; but all such attempts lead to intricate phraseology and a corresponding intricacy of dynamic conception quite beyond the powers of apprehension of the tyro. And even when all is done it is doubtful if the strict canons of logic are quite satisfied. It may be safely said that the introduction to the study of dynamics, Newton's laws of motion, along with the definitions of the physical quantities involved, have not as yet been surpassed.

The train of thought running through Newton's method may be described as a description of everything dynamical that happens in nature consists of changes of position and motion of the parts of a material system. Fixing our attention on one body or particle in the system, we soon perceive by experience that its changes of motion or (more strictly) momentum depend on the evidence of changes of position and motion of the parts of a material system. Fixing our attention on one body or particle in the system, we soon perceive by experience that its changes of motion or (more strictly) momentum depend on the evidence of changes of position and motion of the parts of a material system. Fixing our attention on one body or particle in the system, we soon perceive by experience that its changes of motion or (more strictly) momentum depend on the evidence of changes of position and motion of the parts of a material system.
fully ten years were consumed in his preparations, and in completing his History of the Dutch Republic. This work, published in 1856, established his fame as a historian. This letter is further proof of his moral influence, which was always an important factor in his work.

Motley, a town of Spain, 31 miles S. by E. of Granada, with factories and lead mines. The port is at Calahonda, 61 miles SE. Pop. 16,665.

Motive. In heraldry, a word or short sentence which forms an accompaniment to a coat-of-arms, crest, or household badge; it was called in Scotland the 'ditton.' In France and Scotland it was frequently placed above the crest, in England almost invariably below the escutcheon. A motto is sometimes a religious or moral sentiment, as 'Gardez la foi,' 'Humanitatis,' 'Et deus et pretium recti' (Grafton); it is not unfrequently a heroic exclamation or war-cry, ' Courage sans peur,' 'Forward.' Sometimes it alludes to a peculiar tenure, as ' Free for a blast' (Clerk of Penicuik); while in a great many cases it bears reference to the crest, badge, or some bearing of the escutcheon. Thus, Stuart, Earl of Moray, has for crest a pelican wounding herself, and for motto, 'Salus per Christum' (Blundell). Not a few mottoes are 'canting' or punning allusions to the family name—as 'Scuto amoris Divini,' for Scudamore; ' Ver non semper viret,' for Vernon; 'Pare, fac,' for Fairfax; 'Tune Denuo, colo regem,' for Corderie; and 'Tempe quasi venenar,' for Holden. Two mottoes are sometimes used by the same family—one above the crest, the other below the shield. The motto, ' Dicent et non Droit,' which accompanies the royal arms of Great Britain, is supposed to have been a war-cry, and was used in England at least as early as the time of Henry VIII. It has been assigned to a saying of Richard I., 'Not we, but God and our right have vanquished France.' See Seton's Law and Practice of Heraldry (1863).

Mouflon (Ovis Musimon), the wild sheep of Corsica, Sardinia, central Asia, &c. See AIGAL, and SHEEP.

Moulden. See MCKENZIE.

Mould, or Mouldiness, the common name of many minute fungi which make their appearance, often in crowded multitudes, on decaying or diseased plants and animals and vegetable substances. To the naked eye they often seem like patches of fine cobweb, which are shown by the microscope to consist of cellular threads. Their structure and history are described in the article FUNGI, from the systematic part of which it will be seen that the popular name is applied to many very different forms—e.g. the common White Mould (Mucor mucido), the Bread Mould (Eurysporum Apicellatum), the mouldi of fruit and jam (Penicillium glaucum), &c. See also DRY ROT.

Mouldings. The curved and plane surfaces used as ornaments in cornices, panels, arches, &c., and in all enriched architectural buildings. In classic architecture the mouldings are few in number, and definitely fixed in their forms. The Illustration

Motor-cars. See TRACTION ENGINES, TRAMWAYS, ELECTRIC RAILWAY, GAS-ENGINE. The restrictions that hampered progress were removed in November 1878. See also AIR-ENGINE, COMPRESSED AIR ENGINE, DYNAMO-ELECTRIC MACHINES, ELECTRICITY, STEAM-ENGINE, &c.

Mottram, a town of Cheshire, 6 miles E. of Congleton, on the railway to Stockport, with a paper mill. Pop. 10,000.

Mottram, or Mottram, an ancient English name, from which many place names are derived. The Mottram of O. W. Holmes (1875) is an affectionate tribute.
The fort, which had 26 guns and 435 men, and was  commanded by Colonel William Moultrie (1751-1808), had been hastily built of palmetto logs in two rows 16 feet apart, with the space between filled with sand. The spongy wood of the palmetto was found to resist the cannon balls perfectly.

Moultrie, John, minor poet, born in London in 1759, educated at Eton and Trinity College, Cambridge, took orders, and was presented in 1825 to the rectory of Bajou near Lyons in the Allier, where he was ordained in 1843. He died in 1874. Some little poems of deep tenderness in My Brother's Grave (1837), and The Dream of Life (1843), have kept his name from being quite forgotten; neither the praises of Wordsworth nor the admiration of Coleridge prefixed to an edition of his Poems (1876).

Mound-Builders, a family of gallinaceous birds remarkable for the large mounds which they build as incubators for the eggs. They are natives of Australasia and of the islands in the Eastern Archipelago and Pacific. The Australian Megapodius (Megapodius tawhiti), about the size of common fowl, build mounds of leaves, vegetable refuse, and soil, and add to them year after year until they become immense structures. The largest on record measured 150 feet in circumference. Both sexes work at the nest, in which the eggs are laid in separate holes at a depth of 5 or 6 feet, and left to be hatched by the warmth of the decomposing vegetable matter. The mound of the Nicobar species (M. niveivariusus) seems to be used not only by the original pair, but by their descendants as well. In related genums, Lepisa, the eggs are laid separately in a circle in the centre of the mound, and then deeply covered up with compost. In the genus Tallogallus—represented by the large Brush-turkey (Tallogallus latamani) of Australia—the mounds are used socially by a number of birds.

Mound Builders, the name given to a vanished race of North America, by whose labour the remarkable earth mounds found in the United States were raised. These mounds exist in extraordinary numbers over all the country between the Alleghanies and Rocky Mountains, but chiefly in Ohio, Illinois, Indiana, and Missouri; they are subterranean and can be seen in the Gulf of Mexico as far as the Gulf of St. Lawrence, and they extend at least as far north as the Great Lakes. Their usual height is from 6 to 30 feet, with a diameter of 40 to 100 feet. The majority are simply conical burial mounds, mostly rising from 15 to 25 feet, though one in West Virginia is 70 feet high and over 300 feet in diameter at the base. But very many others of these mounds are defensive, and others again have a religious origin. The fortifications, usually earthworks raised on heights near some watercourse, embrace walls, trenches, watch-towers, and are very skillfully constructed to have been temporary defences: many archaeologists believe that there was a connected line of defensive works from New York to Ohio. In the Mississippi Valley, where the largest mounds are, these forts disappeared, but there is some evidence that the enemies of the Mound Builders had their home in the east—perhaps in the Alleghanies. Some of the Ohio fortresses enclose over 100 acres, the walls of earth, winding in and out, in each case being several miles long. In the alluvial valley of the Mississippi, they have been found, regular, circular, square, &c.—in shape; these have been called ‘sacred enclosures,’ but on very problematical grounds; and the same criticism applies to the identification of the smaller low mounds, from a few inches square to 50 by 100 feet, which have been called ‘temples.’ Of the ‘temple’ mounds, however, there are numerous examples, some very large: one in

various Mouldings.
Illinois reaches a height of 90 feet, and measures 700 by 500 feet at the base; and another in Mississippi is 600 by 400 feet, and its topmost mound is 80 feet above the base. To these must be added the curious mounds constructed in the shape of animals, and sometimes extending to a length of 400 feet. They are most numerous in Wisconsin, but one of the most interesting is the serpent mound near Bush Creek, Ohio (figured and described in *The Century*, April 1890).

As to the identity of the Mound Builders opinions, of course, differ. The general tendency is to recognize their descendants in the Natchez and other kindred tribes whom the Spaniards found on the Mississippi, partly because their chief was both king and deity—he was regarded as the child of the sun—and so we find evidences of the religious feeling and the despotic power necessary to secure the accomplishment of such enormous works. The race may perhaps also have survived in the more highly civilized tribes whom De Soto and his followers met with in Florida and the other southern states. But a comparison of the Mound Builders civilization with that which we find in Mexico when Cortes landed, supplies very strong arguments for connecting these northern Indians, driven south by their nomadic enemies, with the tribes who came from the north and in turn expelled successively the Toltecs and one another, blending their languages and converting the highest civilization which they found there (see MEXICO).

The contents of the mounds support this view. It is evident that the Mound Builders, like the later Mexican tribes, were in the transition stage between the stone and metal ages; copper they had obtained in the same primitive manner as it was obtained in Mexico, but the weapons and tools were stone implements, and knives of obsidian especially—the well-known sacrificial knives of the Aztecs—were common. Their art and manufactures were both of a low standard; but it is well known that the invaders of the Mexican Tableland partly absorbed the civilisation they found there, partly degrading it. Finally, it may be mentioned that the sepulchral mounds yield many evidences of the cruel rites of their builders; and the pyramidal form of the "temples" and mounds is reproduced in the teocalli of Mexico. See Squier and Davis, *Ancient Monuments of the Mississippi Valley* (1848); Conant's *Footprints of Vanished Races in the Mississippi Valley*; Thruston, *Antiquities of Tennessee* (1890); Shepard, *Antiquities of Ohio* (1890); and *State Historical Society of Wisconsin*, *Mound Builders*, (m, 1890).

**Mountain Ash**. See ROWAN.

**Mountaineering.** See ALPINE CLUB.

**Mountain-leather, &c.** See AMPHIBOLE.

**Mountain Meadow.** See DANITES.

**Mountains.** Every one knows what a mountain is, and yet it is hard to give an adequate definition of the term. We may say vaguely that any region the surface of which rises with a more or less steep gradient to a height of 1000 feet or more is a mountain. Mountains differ widely in form—some assuming pyramidal or conical shapes, others forming ridges, others occurring as irregular amorphous masses. Some again stand in more or less isolated positions, while in other cases very many crowd together, forming a billowy mass of elevated grounds, and others, among which are the most prominent mountains of the globe, extend continuously in definite directions as long ranges and chains for hundreds or thousands of miles. Notwithstanding this diversity of form and of grouping, all mountains may be classified as—(a) mountains of accumulation, (b) mountains of elevation, (c) mountains of circumdenudation.

(a) **Mountains of Accumulation.**—Volcanoes may be taken as the type of this class of mountains (fig. 1). These are of course formed by the accumulation of igneous materials around the focus or foci of eruption. Most volcanoes are more or less conical in shape; but in the case of those which have been described by old writers as forming forms of the earth's crust, or of the igneous materials found a passage to the surface. In former times lava seems often to have welled up along the lines of extensive fissures and flooded surrounding regions. Thus, mountains and plateaus have been built up. These are called *plateaux of accumulation*. Many of these, however, have since been highly denuded, so that they now have quite a mountainous appearance (fig. 2). As examples may be mentioned the denuded plateaus of Iceland, the Faroes, Antrim and Mull, Abyssinia, and the Deccan. Of course plateaus of accumulation are not always formed of igneous rocks. Any area of approximately horizontal aequus strata, were it to be elevated to a height of a thousand feet or so, would form a plateau of the kind, such as the plateau of the Colorado. That plateau is geologically of recent origin, and yet sufficient time has elapsed to allow of profound erosion of its surface. Thus, mountains and plateaus of accumulation often owe many of their present features to the action of denuding agents.

(b) **Mountains of Elevation** owe their origin to the folding, crumpling, and fracturing of strata that accompany certain great movements of the earth's crust. They are lines of weakness along which the rocks have yielded to excessive lateral compression by folding and doubling up, during the sinking down of the cool outer shell of the globe upon the more rapidly contracting hot nucleus. The simplest structure presented by such mountains is shown in the Uinta Mountains of Wyoming and Utah. This is a flattened arch of strata, having a breadth of 50 miles and a length of 150 miles, which bulges up to a height of 5000 or 6000 feet above the plains on either side. It shows a broad plateau-like surface which has been deeply eroded. Powell believes that a thickness of 80 miles of strata has been denuded from its surface. In the Jura Mountains we have a series of parallel ridges, each ridge coinciding with a symmetrical anticlinal or saddle-backed arrangement of strata, while the intervening hollows occupy symmetrical synclinal troughs (fig. 3). The tops of the anticlines are all more or less elevated. In the western part of the range of mountains the flexures of the strata are mostly
unsymmetrical (fig. 4). In the Alps and mountain-ranges of similar character the flexures of the strata are frequently reversed—the beds being doubled back so that older strata are inverted and overturned upon younger beds. The accompanying explanation. Mountains of elevation are in the course of time denuded and degraded, and should the land of which they form a part remain long enough above the sea, the whole surface must eventually be reduced to the condition of a low gently undulating plain. Should elevation, which once occurred, this plain becomes a plateau—the surface of which by-and-by is trenched and furrowed by running water, &c., as is the case with the ancient plateaus of Scotland and Scandinavia. 

Age of Mountains. As might have been expected, mountains are of all geological dates, and the age of a large number has been determined. But this has reference chiefly to those that owe their origin to accumulation (volcanic cones) or to compression and folding of strata, during great earth-movements (mountains of elevation). Many of the latter are the result, not of one, but of several successive periods of uplift. It can often be shown that between those periods of movement the mountains have been subjected to long-continued erosion, and partially or even wholly submerged, while newer accumulations of sediment were gradually piled up over their denuded surfaces. The Pyrenees, the Alps, the Jura, the Himalayas, the Andes, and many other conspicuous ranges have been formed by successive upthrusts, separated by longer or shorter periods of degradation and settlement. Some mountains of elevation, which originated in very early geological times, appear to have been denuded down to their very roots—reduced to the condition of low-lying plains. Such plains have subsequently been pushed up bodily and converted into plateaus, which in the course of time have been profoundly modified by denudation, so as now to present the appearance of a rolling mountainous country—the mountains being mountains of circumdenudation (fig. 7). The greatest and loftiest mountains of elevation have all received their latest uplift in comparatively recent geological times. Amongst such young ranges we find that the larger orographic features coincide more or less closely with the greater convolutions, folds, and fractures of the strata. In ranges belonging to much older dates denudation has profoundly
modified the original configuration of the surface—the present orographic features being the result of denudation, determined by the character of the rocks and the geological structure of the ground. Hence in such regions antelids can be found, which are almost unknown, while synclinal troughs, which are strong structures, in place of coinciding with valleys (as in the Jura Mountains, fig. 3), have often come to form mountainous ridges (figs. 6, 7).

Mountmellick. Some attempts have been made to group the various mountain-ranges of the world into systems, more particularly by E. de Beaumont, who maintained the synchronism of ranges situated on lines parallel to one another. The parallelism does not consist in having the same relations to the points of the compass—for these as regards north and south would be far from parallel—but is estimated in its relation to some imaginary great circle, which being drawn round the globe would divide it into equal hemispheres. Such circles were called Great Circles of Reference. But de Beaumont went beyond this, and proposed a more refined classification, depending on a principle of geometrical symmetry, which he believed he had discovered among his great circles of reference. These geometrical speculations have never commended themselves much to geologists. It has been shown that many of the mountain-chains in widely separated regions belong approximately to the same geological age, and may really be strictly synchronous. But much more has yet to be known of the geological structure of the various ranges of the earth before any general grouping of those into systems can be considered reliable. See Alps, Great Britain (Physical Geography), Himalaya.

Mount Vernon, memorable as the residence and the burial-place of General Washington, is on the right bank of the Potomac, in Virginia, 15 miles below Washington. The mansion, and surrounding property were saved from the auctioneer's hammer, and secured as a national possession by the Ladies' Mont Vernon Association, assisted principally by Edward Everett.—Mount Vernon has given its name to a number of places in the United States, the most important of which is a city, the capital of Knox county, Ohio, on the Vernon River, 44 miles by rail N.E. of Columbus. It contains many handsome residences, and the river affords ample water-power for a number of mills and manufactories of doors and sashes, furniture, machinery, &c. Pop. (1890) 6016.

Mouna, Mount. See Broach.

Mouse (Mus musculus), a familiar rodent, representative of a large genus to which rats also belong. It is not necessary to describe the soft 'mouse-colored' fur occasionally varying to white; the scaly tail so useful in climbing; the bright, conspicuous eyes; and the well-hidden cozy nest. Not less familiar is the way in which this tiny mammal has followed man everywhere over the earth; breeding all the year round, and bringing forth four or five young at a birth. Its extraordinary fecundity sometimes causes a plague in a district (as in the wheat-fields of South Australia in 1890). It may be well, however, in the face of continually recurrent discussion, to note the power that at least some of the common mice have of making musical sounds, and of singing, musically and rhythmically, in a high key, with a thin and wiry, but not displeasing quality—something like a weak-voiced canary bird. Mice are occasionally cannibals, and have been known to eat painters' putty with red lint in it. Larger than the above is the beautiful Wood-mouse (M. sylvestris), an abundant pest in the fields and gardens of Europe, notable for the stores of grain and other food which it accumulates among the grass or just under the surface of the ground. Smaller than either, and smallest of British mammals, is the Harvest-mouse (M. minutissimus), which makes a neat globular nest of woven leaves among the grasses and reeds. The White-footed mouse (Hesperomys leucopus), which is exceedingly common in America, has small cheek-pouches, structures best developed in the related family of Cricetinae or hamsters. Corresponding to the European harvest, the Black-footed Field-mouse (M. sylvestricus) is a well-known species of Oce- todon, of which O. humilis measures only about 2 inches in length, not including the tail. Finally, the Water-mouse (Hydromys) of Australia may be noted as remarkably divergent. The name is sometimes extended, as we have seen, to include the smaller species of other genera than Mus, rat being an equally wide title for the larger forms. But, while the wide application of the name is naturally justified, it must be taken to keep the shrews (Sorex) in their entirely distinct, though somewhat analogous, position among insectivora. See Rat, Shrew, Vole.
Mozambique, the mounted body-guard of the kings of Prussia, 400 horses, 400 more noble birth, were organised by Louis XIII, in 1622. They rode grey horses, and were disbanded in 1815.

Mouth. See the articles dealing with Palate, Digestion, Teeth, Tongue, Cærum Osis, Salivation, Sevry, &c.

Movables. See HERITABLE and MOVABLE.

Moville, a seaside resort in County Donegal, on Lough Foyle, 19 miles N.N.E. of Londonderry. It is a calling-station of the Transatlantic steam-packets of the Anchor line. Pop. 1128.

MOVING PLANT (Deinodactylum gneu), a plant of Leguminosae, sub-order Papilionoæ, a native of India, remarkable, as are also some other species of the same genus, for the spontaneous movement of the leaves. See PLANTS (MOVEMENT OF).

Mowing-machine, a machine for mowing lawns and bowling-greens, instead of the scythe. Thilliers' mowing-machine is the best adapted to reaping-machine in principle, chiefly in having revolving instead of horizontal cutters. The first successful mowing-machines in use in Britain were those invented by Shanks of Arbarnath and by Green of Leeds about 1850, whose improved machines are yet the best available to be had.

There are now many rivals to these, chiefly of American manufacture, which are preferable to them on the score of lightness of draught, and consequently ease and speed in the performance of the work.

Moxa is a peculiar form of counter-irritation, which was early practised in the East, particularly by the Chinese and Japanese, from whom it was learned by the Portuguese. One or more small cones, formed of the downy covering of the leaves of Artemisia Moxa (as used by the Chinese), or of the pith of various plants (as of the common sunflower), or of linen steeped in nitre, are placed on the skin over the affected part, and the ends remote from the skin are ignited. The combustion generally proceeds through the cone and forms a superficial eschar on the skin. The surrounding parts usually escape this punishment, with the exception of the hole in the moxa. It is not much used in Europe in consequence of the somewhat severe pain attending it.

Mozambique, the collective name for the territories of Portugal on the east coast of Africa, extends from Cape Delgado to Delagoa Bay, a distance which does not diminish; nothing is more prolix, the Rovuma, the southern (in part), the Maputa, and the western frontiers are formed by Lake Tanganyika, the river Ruo, the Zambesi up to Zumbo, Mashona and Matabele Lands (British South Africa Company's Territories), and the Transvaal. The principal rivers besides those already mentioned, are the Limpopo and Sabi, towards the south. The coast belt is low and swampy; but the interior rises into well-made plateaux, which furnish valuable timber. The soil is naturally fertile, and yields, in addition to maize, rice, manioc, &c., an abundance of natural products, such as cotton, sesame, cocoa-nut, medicinal plants, and indigo-rubber, but very little is done to cultivate them, owing to lack of capital and of means of communication. The imports (cotton goods, beads, hardwood, ivory, gums, hides, spirits, and provisions) average about £508,000 annually; the exports (ivory, ground nuts, indigo-rubber, wax, copal, and oil seeds) about £765,000. The shipping is mostly (seven-tenths) in the hands of British firms. Customs duties are exceptionally heavy; agriculture does not flourish; nothing is little prosecuted, although the country is rich in minerals, in gold, silver, iron, coal, and copper; pearls abound on the reefs off the coast, but are not gathered to any extent; and there is annually a deficit equal to 43 per cent. of the expenditure—some £600,000, which is made good by the home country. The pop. of the province is estimated at one million. There is a railway (1857) of 52 miles from Delagoa Bay to Lourenço Marques. It is well for the Mozambique, Quelimane, and Lourenço Marques, for which see the separate articles. The Mozambique territories are administered by a governor-general, assisted by a governing and a provincial council, and are divided into nine districts, each under a district-magnate.

Mozambique, the capital, stands on a small coral island lying close to the mainland, and has a fine government house, a cathedral, an arsenal, &c. A fort, built by Albuquerque in 1508, two years after he occupied the island for Portugal, stands at the north end of the island. Pop. 7380, of whom 6800 are natives, 250 Banyans, and about 100 Europeans. The city was formerly a great place for the slave-trade, but seems now hardly able to hold its own against Quelimane and Lourenço Marques. Its total trade ranges annually between £250,000 and £320,000.

Mozambique Channel, between Madagascar and the east coast of Africa, is about 1000 miles in length and 400 in average breadth. At its northern extremity lie the Comoro Islands.

Mozarabes. See MORISCOS; and for Mozarabian Liturgy, see LITURGY.

Mozart, WOLFGANG AMADEUS CHRYSOSTOM, was the younger child of Leopold Mozart, Kapellmeister to the Archbishop of Salzburg, and was born in Salzburg on 27th January 1756. Many curious anecdotes are related of his childhood, illustrating an almost incredible precocity of genius, whose early promise, however, was amply fulfilled in his after-life. On his first professional tour through Europe when he was six years old, he was accompanied by his sister Marianne, and under their father's care the children visited Vienna, Paris, Belgium, and London. The greatest triumphs of Mozart were won in Bologna, then the musical centre of Italy. The Philharmonic Academy there suspended all its consulings by which he was eligible for membership, in order to elect this young prodigy of barely fifteen. The wonderful power of his memory was illustrated by a famous feat performed in this Italian tour. The Easter music in the Sistine chapel was jealously kept from the eyes of the populace, and his father, Leopold, was permitted to make it. After one hearing, Mozart wrote from memory a full and minutely correct vocal score. During all the years of childhood and boyhood Mozart had been ever under the immediate care of his father, until his twenty-first year, when, stung by the indignities heaped upon him at the archiepiscopal court, he asked permission to leave it. In September 1777 he left Salzburg for Paris, with his mother as companion and adviser; and from this date began that struggle with the world which was to make him be seen at Mannheim which he visited on the way, he made the acquaintance of a new instrument, the clarionette, which he was the first to incorporate in the modern orchestra, and fell in love with Abuyiasa Weber, the second daughter of a poor man with a family. For many obvious reasons Leopold Mozart was greatly disturbed, and the correspondence between the anxious loving father and the disappointed but always dutiful son throws a flood of light on the relation, as beautiful as it is rare, in which they stood to each other.

In Paris mother and son had to practise the strictest economy, for the mature musician no
MOZART

longer commanded the limitless admiration and interest so readily accorded to the prodigy fifteen years before. In poor lodgings and amid depressing surroundings the mother's health gave way; she died in her son's arms; and Mozart returned to the paternal roof in Salzburg.

He then re-entered the service of the archbishop, he followed him with the rest of the prelate's household to Vienna. Although the archbishop was proud to have such a famous artist in his suite, he hated Mozart, and even the compliments lavished by the young master were made so many occasions to wound his proud spirit. At last, stung by the studied and systematic insult to which he was subjected by his patron, Mozart retorted in language more caustic than prudent, which procured him an instant and ignominious dismissal.

Mozart took lodgings with his Mannheim friends, the Webers, who had now settled in Vienna. The father, his firm friend, was now dead, and Aloysia was married; but her place in Mozart's heart was taken by his younger sister Constanze, a very amiable, vivacious girl, possessing much more than a loving and devoted wife but a wretched manager. She kept her husband up to his engagements, and amused him by her powers as a story-teller; but debts and difficulties increased. Just a month previous to his marriage he produced his little comic opera Entführung aus dem Serail, which paved the way for the next, The Marriage of Figaro, the most delightful of lyric comedies. With his magic wand he touched the somewhat coarse or at least questionable elements in Beaumarchais' play, and these assumed a personal form in a supernatural atmosphere. His contempt of all the pretensions of the nobility, his contempt of the guilty, his contempt of the unfaithful, was so palpable to the world that it had been his lifelong ambition to destroy all such pretensions, to make everyone feel the weight of his contempt.

The opera was more than a success, it created a furor; yet jealousy and court intrigue prevented any reward, any acknowledgment that the greatest living musician was labouring and hungering in their midst. More generous appreciation was offered him in Prague, and, being commissioned to write an opera for the theatre there, he set to work on Don Giovanni. The summer-house and the little stone table on which most of the charming music was written are still shown in the garden of the house, and the noise of converstion, and skittles, he worked apparently undisturbed. The extraordinary success of Don Giovanni made it impossible for the court still to overlook the composer, and he was appointed 'Kammer-Musicius' to Joseph II., his duties being to supply dance-music for the imperial balls at a salary of £20 a year.

Pecuniary embarrassments pressed heavily on his heart since so light, and he writes of gloomy thoughts, which he has to repress with all his might. He had great hopes that a journey to Berlin, and Dresden and Leipzig, in company with his friend and pupil, Prince Lichtenau, might give some chance of bettering his condition; and indeed Frederick-William II. of Prussia was so delighted with him that he offered him the post of Kapellmeister with about £450 a year. But a severe illness prevented him from accepting it. Ever-increasing difficulties induced him to inform the emperor of the king of Prussia's offer, and when Joseph seemed painfully surprised, Mozart, confirmed in his unreasoning affection for a monarch who did so little for him, exclaimed: 'I throw myself upon your highness in behalf of my pupil Joseph II., who has ordered a new opera, Così fan Tutti, but owing to his death, and the indifference to art of his successor Leopold II., the composer reaped no pecuniary benefit. He made one more desperate application for a regular post, and was rewarded by being appointed assistant and successor (without pay for the present) to the Cathedral Kapellmeister, who outlived him many years. His carelessness and improvidence beset him with endless petty embarrassments, and Constanze's frequent illnesses, which necessitated prolonged visits to health-resorts, were an additional and serious drain on the poverty-stricken income. He matriculated in financial ruin too by his heedless and overpowering generosity, often casting his pearls before swine—'false friends,' his sister-in-law terms them, 'secret blood-suckers and worthless people, intercourse with whom ruined his reputation. In 1791, Mozart, fairly broken in body and mind, was an adventurer, a brother freemason, applied to him for help. This was Seihikaneder, a theatre manager, who found himself in difficulties, from which he said only a new opera by Mozart could save him. He suggested the subject himself, The Magic Flute, and, seeing Mozart's failing health and uncertain powers of work, he took care to keep him under his own eye, giving him working accommodation in his own house, and keeping him in good humour with copious supplies of wine and frequent invitations to dinner. For a short time he suffered a great deal from the fall in the value of his health, and entered deeper into his soul, his vision became clearer to read the mystery of life. In six weeks he wrote his three greatest symphonies, in which first throbs that intense expression of passion and pain, the Weltenschmerz' which was to raise Beethoven, his strongman, to the highest place of honour in Music's temple.

In March 1791 he began the Magic Flute, which was produced on the 30th September; and, though it was at first coldly received, it rapidly conquered public opinion, and in the end made the fortune of the lucky Seihikaneder. While he was at work on the opera Mozart received the famous visit about which so much mystery has been made. One night a stranger, now known to have been the steward of a nobleman, Count Walsegg, appeared and commissioned him to write a Requiem in his name, to be performed in the strictest secrecy, and departed as mysteriously as he had come. The month passed, and Mozart was just stepping into the travelling-carriage which was to take him to Prague for the production of a new opera, when the stranger again appeared and reminded him of his promise. The incident made a deep impression on him; and the idea that it was a summons from the other world grew upon the fevered brain and broken heart of the composer. He was really dying, and, as he worked hard at the Requiem, he felt, as he said, that he was writing it for himself. On the 4th of December a few friends met in his room to rehearse the part of the work which was finished, but the dying composer was unequal to the effort. During the evening he seemed, even in unconsciousness, to be occupied with his work until at midnight came the last summons.

He was buried in the common ground of St. Mark's Churchyard, and no friendly eye saw his remains laid in their last resting-place. When the bereaved wife made inquiries a few days afterwards, Count Walsegg, Joseph II.'s hatchetman, changed the subject of his friend's death; and her search for the grave proved fruitless; thus no one knows where Mozart was buried. It was many years after his death that Vienna awoke to sense of her shame and erected a beautiful monument to the memory of her adopted son.

Mozart wrote 624 compositions; he left no branch of the art unenriched by his genius; and he takes a
high place in all. Indeed, in opera and symphony, in spite of the more advanced writings of Wagner and Berlioz, there is the second to none. Gifted with an inexhaustible vein of the richest, most sweet melody, he is at once the glory and the reproach of the Italian school (see OPERA); for, while he surpasses all Italians on their own chosen ground, his strict training in the German school places him beyond rival, and commands the unlimited admiration of every true musician; the great deficiencies of the libretto are forgotten in the charm of the music, in the masterly combinations of effect shown in the finales and concerted pieces, and in the triumph of sustained dramatic power in the last scene. The greatest compliment that could be paid the Magic Flute is that it still holds its place as a classic on the opera-stage, in spite of the most incoherent and incomprehensible plot. The importance of the orchestral music of the opera is not equal to Don Giovanni, and it has been a favourite study with all great opera-composers. Figaro is perhaps the most perfect opera of the three, for in it the plot is slight, and the time required for its development very short.

Of forty-one symphonies there are three which will occupy an honoured place so long as music exists. These are the C major (the 'Jupiter'), G minor, and E². The first preserves its name from the proud and noble rhythm of the first part, and the absolute ease with which the last movement can be played; a complicated counterpoint. In the G minor best the first distinct pulses of that great wave of romanticism and passion which was to flood with its influence all future musical development. The E² is very lively and triumphal in mood and tender withal. It might almost be called a 'Carneval,' written before Schumann had shown the way to such titles. The quartets are very beautiful and exceedingly original; but they are not associated with Mozart's name as they are with those of Haydn. His opus is a creator overshadowed in this branch of the art as is the case in the realm of orchestral writing. His pianoforte sonatas, and those for the violin and piano, are of no great importance except in the development of musical form; but an exception must be made in the case of the Fantasia in G minor, which, like the G minor symphony, foreshadows much of the new school, and reaches even so far as the influence of Schubert. His Masses are all youthful works, with the faults of youth easily recognisable, and the marks of the haste with which they were supplied as occasion required. The Ave Verum, a late church composition, though simple, is very expressive and touching. The unfinished Requiem remains a noble monument of his genius.

The very highest authority on Mozart's life is Otto Jahn (1849; 2 Vols.; 1856), and 1868; see also the life by Nohl (Eng. trans. by Lady Wallace, 1877), that by Meinardus (1842), and the English one by Hofme (1845; 2d ed. 1878). Nohl edited the Correspondence of Mozart, which may be said to be a second to none (1858) of Mozart's second son, Wolfgang Amadeus (1791-1844), who wrote a few compositions of slight importance.

Mozdok, a town of Russian Caucasia, on the Terek, 68 miles N. of Vladikavkaz, with three large annual fairs for horses, sheep, cattle, &c. Kuwait (q.v.).

Mozley, James Bowline, an able theological writer and High Church divine, was born in Lincolnshire in 1813. Educated at Oriel College, Oxford, he became a fellow of Magdalen, vicar of Old Stow, and professor of Divinity at Oxford. His chief books are: The Augustinian Doctrine of Predestination (1553); The Primitive Doctrine of Baptismal Regeneration (1556); Review of the Baptismal Con- troversy (1863); his admirable Hampton Lectures on Mercedes (1865); Oxford University Sermons (1876); Running Ideas in Early Ages (1877); Theory of Development, in answer to Newman (1878); Essay on Historical and Theological (2 vols. 1878), containing among other papers admirable essays on Land and Lather, an over-eulogistic study of Strayford, and a still less successful defence of Cromwell and Dr. Arnold; and Sermons, Parochial and Occasional (1879). Mozley had great intellectual force, subtlety of analysis, and imaginative versatility, but he wrote without facility, and his style is not commensurate in quality with his thought. He died 4th January 1878. See his Letters (1884).—His elder brother Thomas, rector of Plymtree, Devon, is well known as the author of Reminiscences chiefly of Oriel College and the Oxford Movement (1882), and Reminiscences, chiefly of Towneley, with some Sketches of Scholars (1887).

Mozaffar-naggar. See Muzaffarnagar.

Muket, also written Msckettia and otherwise, probably the most ancient town of the Caucasia, and down to the 5th century the capital of the old Georgian kings, stands on the south side of the Caucasia, 10 miles NW. of Tiflis. It contains a cathedral, already existing in the 4th century, in which the Georgian kings were consecrated and buried. When the Poti-Tiflis Railway was constructed, an ancient necropolis was laid bare; the graves were those of a cannibal race, and furnished proof that the modern Georgians are the direct descendants of the ancient Iberi.

Muzensk, a town of Russia, 31 miles by rail NE. of Orel. Pop. 15,967.

Muckton (i.e. 'Great Woolton'), a town of Lancashire, 6 miles SE. of Liverpool. Near it are large quarries. Pop. 4541.

Mucilage is the term applied to the solution of a gum in water—thus, mucilage of acacia, mucilage of tragacanth. The term is also sometimes applied to the natural solution of gum substances found in plants, like the gum of Gu遑a.

Muckers, the popular name of a sect which sprung up at Königsberg in 1835. The movement seems to have originated in the dualistic and theosophic views of John Henry Selönherr (1771-1826) concerning the origination of the universe by the combination of a spiritual and a sensuous principle. The most notable of his followers were two clergymen, J. W. Ebel (1784-1861) and Diestel, both of whom were in 1839-42 degraded from their office. Heupworth Dixon (in his Spiritual Wives, 1868) pointed out the resemblance of the Mucker sect to the China Band (q.v.) and the "black-dog" sects (q.v.). In 1854, at Porto Alegre in Brazil, a band of German Muckers, under a prophetess, were nearly all killed in conflicts with the military.

Mucous Membrane. Under the term mucous system anatamists include the skin, mucous membranes, and true glands, all of which are continuous with one another and consist essentially of similar parts (see SKIN, GLANDS). The mucous membrane is divided into the alimentary mucous membrane (for which see DIGESTION, Vol. III. p. 813), the respiratory (see NOSE, RESPIRATION), and the genito-urinary (see KIDNEYS, &c.).

Mudar (Catalansp. madr, to sleep), a term applied to a reddish-brown species found in India, Persia. &c. The inpsissated juice is used as a purgative and sudorific medicine.
Mudejares. See Moriscos.

Mud-fishes (Dipnoi), a small but very important order of fresh-water fishes, a connecting-link towards Amphibians. There are only two genera, widely separated in geographical distribution—Ceratodus from Queensland and Protopterus from tropical Africa. Of an alleged third genus, 'Lepidosiren' from Brazil, we know extremely little, not enough to warrant its separation from Protopterus. The wide range of distribution, and the discovery in Mesozoic rocks of fossil teeth resembling those of Ceratodus, confirm the impression of ancient origin which is suggested by not a few facts of Dipnoan anatomy, such as the persistent notochord without distinct vertebrae, the intestinal spiral valve, the cloaca, the abdominal pores, &c. (see Fishes). On the other hand the mud-fishes are in other respects almost amphibians, for the swim-bladder functions as a single (Ceratodus) or double (Protopterus) 'lung,' along with which gills also persist. The Dipnoi are thus important connecting-links. The limbs are peculiar in the possession of a central axis, which in Ceratodus bears rays on each side. The body is covered with flat scales, is from four to six feet in length, and bears a symmetrical tail. Ceratodus seems to feed on decaying leaves and the like, Protopterus on fish, frogs, insects, &c.,

while 'Lepidosiren,' though described by the natives as feeding on roots, is said to have teeth suited to carnivorous diet. The nostrils open posteriorly into the mouth, a condition occurring in no other fish, unless Myxine be reckoned as such. Air is taken into the lungs at the surface of the water, and this mode of respiration becomes more emphatic when the fishes venture to wriggle ashore, as Ceratodus is said to do, or get into thick muddy water, or when the dry season begins to desiccate the pools. It is then in fact that Protopterus most deserves its popular name, descending into the mud, rounding off a nest for itself, and becoming more or less dormant. 'The mud around one of these nests becomes very hard, and the balls thus formed have been dug out, and, without breaking, have been brought to Europe or North America. A short immersion in water serves to release the fish, which will live for some time in confinement. Both Ceratodus and Protopterus are esteemed as food. The development of all the forms is still quite unknown. The term 'mud-fish' is also applied to a Ganoid (Amia calva) not uncommon in some of the fresh waters of the United States. It attains a length of two feet, is carnivorous in diet, and gulps air at the surface of water, the air-bladder having truly pulmonary functions.

See Ceratodus, Fishes, Lepidosiren; also Günther's Study of Fishes (Edin. 1860); Howard Ayers, Jenaische Zeit. xviii. 1885, with literature.

Mude, CHARLES EDWARD, founder of the celebrated library which bears his name, was born at Chelsea in 1818. Having started as a bookseller, he established his library in 1842, which became a limited company in 1894, and had 25,000 members in 1890, the annual receipts being £100,000. He published poetical Stray Leaves (1873), and died 28th Oct. 1890. See Book-trade.

Mukli, often spelt Moodkee, a village of the Punjab, India, 26 miles s. of the Salt, and on the old road from Rawalpindi to Kasur. It was the first battle in the Sikh war of 1845-46 was fought (18th December 1845), when the British, under Sir Hugh Gough, repulsed the Sikhs, and Sir Robert Henry Sale, 'Fighting Bob,' was killed.

Mud Volcanoes. See Volcanoes.

Muezzi (Arab. Mu‘izz or Mu‘izzin; sometimes Muizzlid), the official attached to a Mohammedan mosque, who announces the different times of prayer. See Mohammed, p. 249.

Muff, the Turkish Grand Muff or Sheikhlul-Islam is the head of the great corporation of Ulem (q.v.), the interpreters of the Koran, by whose decisions (when written down, Feticus) the Cadi have to judge. The chief of the Ulem is little less powerful than the Grand Vizier.

Muggletonians, a sect that flourished in England about the middle of the 17th century, and of which the founders were John Reeve and Lodowick Muggleton (1607-97), obscure men, but who claimed to have the spirit of prophecy. Muggleton was a journeyman tailor. He professed to be the 'month' of Reeve, as Amen was of Moses. They aimed at being the two witnesses of Rev. xi. They asserted a right to curse all who opposed them, and did not hesitate to declare eternal damnation against their adversaries. They favoured the world with a number of publications, one of which, in which they yearly directed the Parliament, and Commonwealth of England, and to his Excellency the Lord General Cromwell—was entitled a Remonstrance from the Eternal God. The prophets were at that time imprisoned as nuisances in Old Bridewell. Another publication was a General Epistle from the Holy Spirit in 1756; Muggleton's writings were collected again in 1832. He had assailed the Quakers, and was answered effectively by Penn and George Fox. He denied the doctrine of the Trinity, held anthropomorphist opinions, with many strange doctrines over and above, as that the devil became incarnate in Eve, &c. A few Muggletonians lingered in England well into the 19th century. See Jessopp's Coming of the Frians, and other Essays (1888).

Mugwumps, a title conferred, during the United States presidential election of 1884 (New York Sun, June 15), on such Republicans as threw over the nominee of their party for Cleveland, the Democratic candidate, in the interests of civil service reform. The title implied a belief that these Independents set themselves up as superior to their former associates.—The word means 'big chief' in the Algonquin Indian, and it was adopted by Gen. Eliot, who published it 'Mugwump,' employed it to translate 'leader' and 'duke' (as in Gen. xxxvi. 15) in his Indian version of the Bible.

Mühlberg, a town of Prussian Saxony, on the Elbe, 36 miles S.E. of Wittenberg. Top. 3411. Here, on 24th April 1347, the Emperor Charles V. defeated John Frederick the Magnanimous, Elector of Saxony. See Schmilka.

Mühlhausen, a town of Prussian Saxony, on the Unstrut, 25 miles by rail NW. of Gotha. An important imperial free city in the 13th century, it came to Prussia in 1802, to Westphalia in 1867, and again to Prussia in 1815; and it is still an active centre of commerce, with manufactories of woolens and cotton goods, hosiery, &c. Top. (1873)
MUIR

21,054; (1833) 25,141. See works by Herquet (1874), Pfaff (1874), and Steephan (1886).

Muir, John, a distinguished Sanskrit scholar, was born in Glasgow in 1810, and studied at the university there and at Haileybury, and at eighteen went out to Bengal to join the East India Company's Civil Service, in which he remained for twenty-five years. His last years were spent in Edinburgh, where he died, March 7, 1882. He was a munificent patron of learning, and himself a scholar of unusually wide intellectual and spiritual sympathies. He founded and endowed a chair of Sanskrit in Edinburgh, as well as prizes for high attainments in that language, and also provided the funds for a lectureship in comparative religion. His great work was his Original Sanskrit Texts on the Origin and History of the People of India, their Religion and Institutions (5 vols. 1858-70; 2d ed. 1865-73). Another book is Metrical Translations from Sanskrit Writers (1878).

Sir William Muir, his brother, was born in 1819, and at eighteen joined the Bengal Civil Service after having attended lectures at both the universities of Edinburgh and Glasgow. He rose rapidly in rank, was made K.C.S.I. in 1867, and was lieutenant-governor of the North-west Provinces, 1868-74, and Financial Minister to the government of India, 1874-76. After his return to England he sat on the Council of India, 1876-83, when he was elected Principal of the university of Edinburgh. Sir William Muir is an eminent Arabic scholar, and his Life of Mahomet (4 vols. 1859-64) and Annals of the Early Caliphate (1883) are works of solid and enduring value. Other books are The Cord, its Composition and Teaching, and the Testimony it bears to the Holy Scriptures (1878); Extracts from the Cord (1880); and The Early Caliphate and Rise of Islam, the Rede Lecture for 1881.

Muirkirk, a town of Ayrshire, 26 miles E. by N. of Ayr, blithely situated, 720 feet above sea-level. It is the seat of great ironworks, dating from 1787. Pop. (1871) 2376; (1891) 3329.

Mukaddasi, an Arab geographer, born at Jerusalem, voyaged extensively for twenty years, and described the Moslem lands in a work published in 985 A.D. It was edited by De Goeje in 1877; and the part relating to Syria and Palestine was translated from the Arabic for the Palestine Pilgrim's Text Society in 1887, by Guy Le Strange.

Mukden, or Moukden, capital of Manchuria, is situated in the southern part of the country, on a branch of the river Liao, 425 miles N.E. of Peking. Mukden is the Manchu name; the Chinese call it Shingking, its present official title. The town is surrounded by a good masonry wall, a parallelogram in shape. Outside this the suburbs extend for one to two miles and are protected by a mud wall. The imperial palace stands in the centre of the city, enclosed within a third separate wall. Previous to 1626 the town was called Shenyang; in that year Nurhach, the founder of the present reigning family in China, made it his capital and called it Mukden. The Irish and Scotch Presbyterians are very active in the place; they conduct also a medical mission which is very successful. There is, too, a Roman Catholic mission. Numerous temples adorn the city. About four miles to the east is the tomb of Nurhach. Mukden contains other conspicuous buildings. The female high school is noted. Good coal exists in the vicinity. Its port is Newchwang (q.v.); and it is an important point on the Russian railway system which connects the Siberian line with Port Arthur and the China Sea.

Mulatto. See Negro.

Mulberry (Morus), a genus of trees of the natural order Moraceae, natives of temperate and warm climates, with deciduous leaves, unisexual flowers in short, thick spikes, a 4-parted perianth, containing either four stamens or one pistil with two styles, the perianth of the female flowers becoming accunct and closing over the small pericarp, the whole spike coalescing into an aggregate fruit.—The Common Mulberry, or Black Mulberry (M. nigra), is a native of the middle parts of Asia, but was introduced into the south of Europe more than a thousand years ago, and is now almost naturalised there. It is a low tree, much branched, with thick rough bark, and broad heart-shaped leaves, which are unequally serrated, and very rough. It is cultivated in the middle parts of Europe, and succeeds well in the south of England, but in the northern parts of Britain it requires a wall. The perianth and stigmas are roughly ciliate, and the fruit is of a purplish-black colour, with dark red juice, fine aromatic flavour, and subacid sweet taste. The fruit is much esteemed for dessert; an excellent preserve and a pleasant light wine are made of it. The tree often produces its fruit in prodigious quantity. The wood is employed in cabinet-work, but is not of much value. The leaves are sometimes used for feeding silkworms. The Black Mulberry lives long; trees still existing in England are known to be more than 300 years old. It is propagated by seed, by suckers, by layers, or by cuttings. It succeeds best in a rich light soil.—The White Mulberry (M. alba) is a native of China, and has been there planted from time immemorial for the sake of its leaves, which are the best food for silkworms; on this account also it has been cultivated in the south of Europe since about 1540. In North America it does not succeed farther north than 43° lat., being somewhat more impatient of frost than the Black Mulberry. The perianth and stigmas are smooth; the fruit is almost white, and is much less palatable than that of the Black Mulberry, although in this respect there is great difference among the many varieties. A rob made of it is useful in sore throat. The best variety for feeding silkworms, on account of its rapid growth and abundant leaves, is that called the Philippine Mulberry. In India the White Mulberry is treated as a bush, and cut down twice a year; the shoots, stripped of their leaves, being thrown away, although the bark has long been used in China and Japan for making paper. It grows readily from cuttings. The root has a considerable reputation as a vermifuge.—The Red Mulberry (M. rubra), a native of North America, abounding
particularl,y on the lower parts of the Missouir, endures severe frosts much better than earlier of the preceding, and is therefore preferred for cultivation in some parts of Europe. Its fruit is deep red, and almost as pleasant as the Black Mulberry. It forms a tree 60 to 70 feet high, with a circumference of about six feet; the wood is fine grained, strong, and adapted even for shipbuilding, but cannot be procured in any quantity for that purpose. — The Indian Mulberry (M. Indica) has black fruit of a delicate flavour, and the leaves are extensively used for feeding silkworms in China, Cochin-China, and Bengal. — M. atrapurae has been introduced into India from China for feeding silkworms. M. Mauritiana, a native of Madagascar and Mauritius; M. cellidifolia and M. corystifolia, Trent reputation as a Greek, a national sentiment in the north of India; and M. Cashmeriana, a native of Cashmere, produce pleasant fruit. M. dulcis, a native of the north of India, is said to be superior in flavour to all others.

He was early addicted to clothing from the bark, using for this purpose the bark of small branches about an inch in diameter, which they unerringly detect, and then, scraping off the epidermis, they press and beat the moist slips together. The paper also which is used in Japan and many parts of the East is in great part made from the bark of the young shoots of this plant, which for this purpose is boiled to a pulp, and treated somewhat in the same way as the pulp of rags in Europe. When the shoots are cut, new ones sprout up very rapidly. Silkworms eat the leaves of the Paper Mulberry. The fruit is oblong, of a dark-scarlet colour, sweetish, but insipid.

Mulcaster, Richard, philologist (died 1611), was a scholar of King's College, Cambridge, in 1588. He was removed to Oxford, and was chosen student of Christ Church, quickly becoming eminent for his knowledge of eastern literature. In 1591 he was appointed master of Merchant Taylors' School, and in 1596 master of St Paul's School. He enjoyed great reputation as a Latin and Greek scholar, and a successful schoolmaster. His English and Latin works were celebrated in their day, the principal being Positions, &c. necessaries for the Training up of Children (Lond. 1581) and Elements or the Right Writing of our English Tongue (1592). He was also early addicted to dramatic composition, and assisted in the performance of plays before Queen Elizabeth.

Mulder, Gerard Johannes (1802-80), was professor of Chemistry at Utrecht, and was best known from his investigations on protein and vegetable physiology.

Mule, the hybrid offspring of the male ass and the mare, much used and valued in many parts of the world, is the most of hybrid strength, head, gait, and tail show very distinctly the 'potency' of the ass; but in bulk and stature the mule is nearer the horse, and seems to excel both its parents in sagacity, muscular endurance, sure-footedness, and length of life. Though never much used in Britain (save in some places for tram-cars), it has been common from ancient times in many parts of the East, and is a very important animal in most of the countries round the Mediterranean, and in the mountainous parts of South America. The best European breeds are found in France, Spain, and Italy; those of Kentucky, Missouri, Minnesota, and Mexico are also renowned. The carrier-mules of South America and elsewhere are driven in troops, each led by a bell-bearing old mare. They follow with such docility and affection that when the trodes mingle in their halting-places they are readily separated by securing the leaders. In ancient times mules were often reserved as the peculiar steeds of princes, and they are still used to draw the carriages of Italian cardinals and other ecclesiastical dignitaries. Mules are very sure-footed, strong of limb and firm of hoof, clever at passing steep places and sharp turns, easy to please with food. They may be ridden, driven, or used for pack purposes. Their flesh is edible.

The fact that mules are generally sterile has given rise to the common mistake of supposing that sterility is a necessary consequence of hybridization. Indeed, regards as hybrids may be successfully crossed by horse or ass, though the more numerous males seem to be constantly sterile. The hinnies or companion hybrid of the mule, the offspring of a female ass and a stallion, is not common, and is decidedly inferior in size, strength, and temper, and more frequently sterile. In some cases, and for the Spinning-mule, see SPINNING.

Mulgrave Islands, a name given to some of the Marshall Islands (q.v.) from their discoverer, the navigator Lord Mulgrave (1744-92).

Mülhausen (Fr. Mulhouse), a town of Alsace-Lorraine, on the Ill and the Rhine and Rhine Canal, 68 miles by rail S.W. of Strasbourg and 20 NW. of Basel. It consists of three parts, the old town, its suburb, and the new town, and the town, on account of the manufactures of paper, is a place of first-rate industrial importance. The cotton manufacture employs 16,000 workpeople in the town and 60,000 in the adjacent villages. Besides this, it has printing and dye works for cotton, linen, calico, wool, and silk fabrics, chemical factories, iron and other metal works, and shops for making machinery, railway plant, &c. Pop. (1821) 13,027; (1861) 45,887; (1882) 60,759; (1890) 76,413. Mülhausen, which existed as early as 717, was made a free imperial city by Rudolf of Hapsburg in 1248. By siding with the Protestant cantons in the 14th century, it was enabled to maintain a certain degree of neutrality in the feuds between the empire and France. In 1515 it joined the Swiss Confederation, and in 1528 adopted the Reformed faith. But in 1798 it was incorporated with France, and began to come to the front as an industrial place after 1829. It is noted for the excellent arrangements made for the housing, &c., of the working-classes. It became a town of the German empire after the war of 1870-71. See Histories of the town by De Sablère (1856) and Metzger (1883).

Mühlheim, a manufacturing town of Rhenish Prussia, on the river Ruhr, 16 miles N. of Düsseldorf. It has great ironworks and an extensive trade in coal. Pop. (1875) 15,445; (1890) 27,702.—MÜLHEIM-AM-RIEHE, 3 miles above Cologne, carries on extensive manufactures of silk, velvet, lace, leather, &c. Pop. (1875) 17,550; (1885) 24,975.

Mull, an Argyllshire island, the largest of the Hebrides after Lewis and Skye, is separated from the mainland by the Sound of Mull (10 miles long and 14 to 34 miles wide), and is engirt by a number of smaller islands—Gometra, Ulva, Staffa, etc. It is 547 sq. m. in area, and its maximum length and breadth of 30 and 29 miles, but is so deeply indented, especially towards the
Atlantic, by a dozen sea-locks and bays—the chief, Loch-na-Keal and Loch Scridain—that the coast-line cannot be less than 300 miles. The valley of the esplanade is a quarry of fine red granite in the south-west; and the surface is mountainous. Benmore (3185 feet) is the loftiest summit, Ben-achlach the most beautiful, where there is much that is beautiful—these misty heights, the stretching moors, the sea-cliffs at Carsay, the termed basaltic plateaus, the glens, streams, and lakes, and the patches of wood and green pasture. The climate is good for the Highlands, and the soil of fair fertility, but grazing answers much better than corn-crops. Tobermory, in the north, 28 miles WNW. of Oban, is the only town, but was founded in 1788 at the head of its sheltered harbour, and has a pier (1864), a telegraph, a new water-supply (1882), and 1200 inhabitants. Arrochar and Duart Castles are interesting ruins; and Maccullon's Cave was pronounced by Dr Johnson the greatest natural curiosity he had ever seen. Pop. (1851) 7455; (1891) 4691, of whom 4013 were Gaelic-speaking. See Galloway (Mull of), Kintyre.

Mullein, the common English name of the genus Verbascum, belonging to the Scrophulariaceae, and containing some eighty species, of which some six (Great Mullein, White, Dark, Moth, &c.) are naturalized in the United States. The leaves and stem (2 to 4 feet high), of the common and larger species, are covered with a dense, woolly, or silky flowers; the flowers form a dense spike a foot long. A mucilaginous decoction of the leaves is used to allay coughs and as an emollient application.

Müller, F. Max.—See Max-Müller.

Müller, George, founder of the Orphan Homes, Ashleydown, Bristol, was born near Halberstadt, Prussia, September 27, 1805. While in training for the ministry he was dissipated in his habits, and at sixteen he was sent to prison for defrauding an hotelkeeper. He went to Halle as a student of divinity, and a visit to a private meeting for praise and prayer proved the turning-point in his career, and in 1826 he began to preach and teach, and took up his abode in free lodgings provided for poor divinity students. Through Thieluck's advice he came to London in 1829, and studied the New Testament in Chaldee with the view of becoming a missionary to the Jews. He settled at Teignmouth as minister of Ehenezer Chapel, and in the conduct of his church abolished collections and depended on voluntary gifts. In 1835 he printed proposals for the establishment of an Orphan House, which took shape in 1836 at Bristol. As the result only of prayer to God, he announced that he had received £81,441 up to 1836 on behalf of the orphans, who then numbered 297. By 1875 upwards of 2000 children were lodged, fed, and educated. In 1889 it was announced that the Orphan Homes and associated enterprises cost about £36,000, which sum was the result of faith and prayer and voluntary subscriptions on the part of the public. Müller visited the East on an evangelistic tour in 1889. He has published various volumes of Travels and Discoveries with George Müller (1837). Other three portions were published, 1841-66.

Müller, Johannes, one of the most eminent physiologists of the 19th century, was born at Coblenz on 14th July 1801, studied at Bonn and Berlin, chiefly anatomy and zoology; and in 1826 went to the University of Würzburg as Privatdocent at Bonn; in 1833 he succeeded Rudolph as professor of Anatomy and Physiology at Berlin, and held that post until his death, 22nd April 1838. He is regarded as the founder of modern physiology, on the ground that he summed up the work of his predecessors, initiated the methods of experimental and microscopic investigation of physiological properties, himself carried out and recorded most valuable researches with the mechanism of sight, hearing, and voice, and the chemical and physical properties of chyle, lymph, bile, and urine, and studied in an original and fruitful way the phenomena of reflex action and the glands. Moreover, his Handbuch der Physiologie der Menschen (2 vols., 1833-39) exercised a great influence as a textbook of the science, and Müller counted amongst his pupils several men who soon stood in the forefront of German science, such as Helmholtz, Velork, Du Bois Reymond, &c. Müller was scarcely less eminent as a student of comparative anatomy; he of course rapidly and accurately, and possessed a remarkable insight into the interrelations of structural parts. In this department of work his most famous memoirs were those on the Amphioxus, on Fishes, the Echinodermes, and the Cestians. Several of his works were translated into English between 1830 and 1849.

Müller, Johannes von, historian of Switzerland, was born 31st January 1752, at Schaffhausen, studied at Göttingen under Heyne, Schlözer, and others, and in 1772 was appointed professor of Greek at Schaffhausen. Already he had commenced the translation of M. Schott's Greek and Latin documents. From 1774 to 1780 he lived in Geneva, taught there, and wrote his Allgemeine Geschichte (3 vols. 1810), and published the first volume of his great work, Geschichte der Schweiz. Shortly afterwards he was given the professorship of History and a librarianship at Basel, but resigned both posts in 1783. In 1786 he became librarian and councillor of state to the Elector of Mainz, and began the publication of his larger Geschichte der schweizerischen Eidgenossenschaft (5 vols. 1786-1808; improved ed. 1828). In support of the confederation of the German princes he wrote a De ordina- dung des Fürstenthumbs (1787). In 1792, when Mainz was taken by the French, he went to Vienna, where the Emperor Leopold nominated him a member of the privy-council; but, as a Protestant at a Roman Catholic court, he did not see much prospect of advancement, and in 1804 left Vienna for Berlin, where he was appointed historiographer of the Hohenzollern family, and wrote Uber die Geschichte Friedrichs 1., Uber den Untergang der Freiheit der Alten Völker, and Verzeichniss der Zeitrechnungen der Vorwelt. He was introduced to Napoleon, who in 1807 appointed him the work of state secretary in the new kingdom of Westphalia; but died at Cassel, 29th May 1809. His Sammlungsiche Werke were published, 27 vols. Tübingen, 1800-17; new ed. 40 vols. Stuttgart, 1831-38; See Lives by Heeren (1820), Döring (1835), Monnard, in French (1839), and Thiersch (1891).

Müller, Julius, a German theologian, was born at Briesg, April 10, 1801, brother of Karl Otfrid Müller, the antiquary. He studied at Basle and Göttingen, at first law, next theology, and after a severe mental struggle adopted opinions in religion opposed to those of the Rationalists. In 1825 he was appointed pastor at Schönbrunn, south of Breslau, in 1831 second university preacher in Göttingen, in 1834 extra-ordinary professor of Theology there, next year ordinary professor in Marburg, and in 1839 in Halle. Here he died, 27th September 1858. His reputation as a theologian chiefly rests upon his great work on sin, Die Christliche Lehre von der Sünde (Bresl. 1830; 6th ed. 1878). It was translated into English by W. Urwick (2 vols. 1868). Another work was Dogmatische Abhandlungen (1870). Müller, together with Neander and Nitzsch, edited from 1856 to
Müller, Karl Offried, classical archaeologist, was born 28th August 1797, at Brieg, in Silesia, studied at Breslau and Berlin, and in 1819 was appointed professor of Archaeology and director of the Philological Seminary at Göttingen. He died at Athens, 1st August 1840, whilst on a tour through Italy and Greece. His great design was to embrace the whole life of ancient Greece, its art, politics, industry, religion, in one warm and vivid conception—in a word, to cover the skeletons of antiquity with flesh, and to make the dry bones live. Thus his activity ranged over the whole field of Greek antiquity. We are indebted to him for many new and striking elucidations of the geography and topography, literature, grammar, mythology, manners and customs of the ancients. His work on the Dorian (Die Dörfer; Eng. trans. 1839) forms the 21 vol. of his Geschichte Hellenischer Staaten und Städte (new and improved ed. 1841), his principal production; the first vol. deals with Oechomenos and the Minyans. The treatises on the ancient Macedonians (1825) and on the Etruscans (2 vols. 1828; new ed. 1877-78) continue the same line of investigations. Other valuable works from his pen are Ancient Art (1830; new ed. 1878; Eng. trans. 1847); System of Mythology (1825; Eng. trans. 1844); and History of the Literature of Ancient Greece (1846), undertaken at the request of the British Society for the Diffusion of Useful Knowledge, translated into English by Sir George Cornewall Lewis and Dr Donaldson, the latter of whom continued the work down to the taking of Constantinople. The German original was published by Müller’s brother (2 vols. 1841; new ed. 1882-84). Müller issued useful critical editions of Varro, De Lingua Latina (1833); Festus, De Significatione Verborum (1830); and Aschylus, Eumenides (1833-35). See Memoirs by Lücke (1841) and F. Ranke (1870).

Mullet (Mugil), a genus of neanopterous bony fishes, type of the family Mugilidae. The members are common coast fishes, often frequenting brackish water. They eat mud, which they crush and sift within a filter to the gills, rejecting the useless stuff, swallowing the rest for the sake of the organic debris it contains. The mouth has at most feeble teeth; the gill-rakers form an effective sieve; the stomach is rather like a bird’s gizzard; the intestines are exceedingly long. There are about seventy species, some of which attain a weight of 10 - 12 pounds. As they are edible and sometimes highly esteemed, the mullets ought to be more cultivated. Among British species M. octo-radiatus, M. capito, M. auratus may be noted. A species from the fresh waters of Central America (M. proboscidea) has a pointed fleshy snout. The Mediterranean mullet formed a favourite Roman dish, and their roes preserved are made into a delicacy.

The so-called ‘red mullets’ (Mullus) are quite different from the above, and not far removed from perches. The body is slightly compressed, and covered with large, thin scales. There are two long, erectile barbels and feeble teeth. About forty species, mostly from tropical seas, are divided among a number of sub-genera. There is only one European species (M. barbatus), of which the so-called ‘smullet’ is probably the female form. It occurs on the southern and western coasts of Britain, and is much esteemed as a delicacy. The male seems to be smaller than the female, which in British waters rarely exceeds two pounds in weight.

The colour of the smullet is pale pink, with three or four yellow longitudinal stripes; but where any of the scales have been rubbed off beautiful tints of purple and bright red appear. This takes place also during the struggles of the fish when dying; and the Romans were therefore accustomed to bring smullets alive into their banqueting-rooms that the guests might see them die, and enjoy the brilliant display of colour before eating the fish. ‘The fishermen of our times,’ Günther says, ‘attain the same object by scaling the fish immediately after its capture, thus causing a permanent contraction of the chromatophores (colour-cells) containing the red pigment.’ See Günther’s Study of Fishes (Edin. 1880).

Mullet. See HERALDY.

Mullingar, the chief town of Westmeath, in Ireland, 90 miles WNW. of Dublin by rail, on the Royal Canal and the river Brosna. It is an important trading town, has large infantry barracks, and is a centre for anglers visiting the Westmeath lakes. Pop. (1881) 5426; (1891) 5323.

Mullion, the upright division between the lights of windows, screens, &c. in Gothic architecture. Mullions are rarely met with in Norman architecture, but they become more frequent in the Early English style, and in the Decorated and Perpendicular are very common. They have sometimes small shafts attached to them, which carry the tracery of the upper part of the windows. In late domestic architecture they are usually plain. See ANGULAR SKEW OR WINDOW.

Mullock, Miss. See CRAIK.

Mulready, William, genre-painter, was born at Ennis, in Ireland, 1st April 1786. When a boy he went to London with his parents, and at the age of fifteen entered as a student in the Royal Academy. Having tried classical subjects and landscape, he soon found his true sphere in genre-painting—painting subjects such as ‘A Roadside Inn’, ‘Horses Baiting’, the ‘Barber’s Shop’, and ‘Punch’ (1812). ‘Boys Fishing’ (1813), ‘Idle Boys’ (1815). He was elected an Associate of the Royal Academy in November 1815, and an Academician in February 1816. He also worked indefatigably at portrait-painting and the illustration of children’s books; designed the famous

Münchhausien, KARL FRIEDRICH BIERONY,

Münchhausen, Karl Friedrich Gebony,

Münchhausien. This character is said to have

Münchhausen's Narrative of his Marvellous Travels and Campaigns in Russia (Lond. 1785). They were compiled by Rudolf Erich Ritspe, an expatriated German (whose financial enterprises were not creditable to him)

Münchhausien. His collection of his marvellous travels and campaigns in Russia (Lond. 1785). They were compiled by Rudolf Erich Ritspe, an expatriated German (whose financial enterprises were not creditable to him), and by other hack writers. The book went rapidly through several editions; and in 1786 appeared the first German version edited by the poet Bürger. Ellisen's edition (reprinted in 1800) is enriched by an admirable introduction. So is Seccenbüh's English edition (1804), which points out many hits at Bruce, Montgollied, &c. Several of the adventures ascribed to the baron occurred in Belad's Facetiae (1568); others in Lange's Deliciae Academicae (1763). See Müller, Münchhausen (Lips. 1834).—A Freiherr von Münchhausen (1813–86) became in 1850 head of the government of Hanover; and after the annexation of Hanover by Prussia (1866) he made himself a champion of the national party.

Münich, capital of Bavaria, is situated in a flat, barren plain, 1700 feet above the sea-level, chiefly on the left or west bank of the impetuous Isar, a tributary of the Danube. By rail it is 440 miles SSW. of Berlin, and 101 2/3 W. of Stettin. The town area is 5672 m., and has about 28,813 bridges, including a railway bridge, span the river to the suburbs on the right bank. The elevated site of the city and the neighbourhood of the Alps render it liable to sudden changes of temperature, sometimes ranging over 29° in twenty-four hours. The average temperature for the year is 52°. The rainfall is 48 1/2 inches. In 1895 the population was 1,268,322, of whom about 84 per cent. were Roman Catholics; by 1890 it had increased to 230,710; in 1880 it was 230,023.
MUNICH and the administrative centre of Bavaria, has dominated the history of Germany, and is the richest and most important city in the country. It is famous for its art and architecture, and for its liberal university. Munich is also known for its beer, which is produced in large quantities, and for its famous glazes and pottery. The city is located on the River Isar, and is surrounded by rugged mountains and picturesque valleys.

In the 18th century, Munich was the capital of the Bavarian Kingdom, and was the centre of the Bavarian state. It was also the centre of the Bavarian aristocracy, and was known for its lavish lifestyle and its love of art and music. Munich was the home of many famous artists, including the painter and architect, Max Liebermann, and the sculptor, Max Klinger.

In the 19th century, Munich was the centre of the German Romantic Movement, and was home to many of the leading figures of the movement. It was also the centre of the Bavarian National Movement, and was the site of many important political events.

In the 20th century, Munich was the centre of the Nazi Party, and was the site of many important political events. It was also the centre of the German Resistance Movement, and was the site of many important political events.

Today, Munich is a modern city, with a thriving economy and a rich cultural life. It is known for its beautiful architecture, its world-renowned universities, and its vibrant nightlife. It is also known for its magnificent art collections, which include some of the finest in the world, and for its world-famous museums, which include the famous Museum of Modern Art, and the famous Museum of Fine Arts.

MUNICH has a long and rich history, and has been the centre of many important events in the history of Germany. It is a city of great beauty, and a city of great cultural significance. It is a city that is worth visiting, and a city that is worth knowing.
towns became of considerable importance during the middle ages, so few municipal buildings remain. This arises from the circumstance that the resources of the Portuguese palace in Rome were applied to aid the bishops in the erection of the great French cathedrals, and the townspeople used these cathedrals as their halls of assembly, and even for such purposes as masques and amusements.

**Municipality** (from Lat. municipium, from munus and capio, "one who enjoys the rights of a free citizen") was the performance by common councils of local self-government, the governing body in such a town. Municipal institutions originated in the times of the Roman empire. The provincial towns of Italy, which were from the first Roman colonies, as also those which, after having an independent existence, became members of the Roman state, though subjected to the rule of an imperial governor, were allowed to enjoy a right of regulating their internal affairs. A class of the inhabitants called the curia, or decuriones, elected two officers, called duumviri, whose functions were supposed to be analogous to those of the consuls of the imperial city, and who exercised a limited jurisdiction, civil and criminal. There was an important functionary in every municipality called the defender civilitas, or advocate for the city, the protector against illegal acts of the part of the imperial governor. The municipal system declined with the decline of the empire, yet it retained vitality enough to be afterwards resuscitated in union with feudalism, and with the Saxon institutions of Britain. Some cities of Italy, France, and Germany, have indeed survived their present magistracy by direct succession from imperial Rome. For British Municipalities, see BOROUGH, CITY; see also FREE IMPERIAL CITIES.

**Münster**

**Münster, capital of Westphalia, stands on a small stream, by rail 101 miles N. by E. of Cologne and 106 SSW. of Bremen. It retains numerous remains of municipal architecture. It is sometimes called Romanesque and Gothic cathedral (12th to 14th c.); Our Lady's Church, Gothic (14th); the Gothic church of St Lambert (14th c.); the church of St Ludgerus, also Gothic, dating from 1380; the Gothic town-hall, in which, in 1484, the peace of Westphalia was signed. The city contains a museum, and the building of which once formed part of the castle, built in 1767, and surrounded by fine pleasure-grounds, including botanical gardens; and the 16th-century town-warehouse, in which are preserved some rare pictures of the old German school. The old Catholic university of Münster was dissolved in 1818; there is now an academy, with a Catholic theological and a philosophical faculty, and about 470 pupils. Attached to it are a library of 123,000 volumes, a natural history museum, and collections of art and antiquities. The great industrial product of Münster include woollen, cotton, and silk fabrics, and paper, besides dyeing, printing, and enamelling. The trade is limited to linens, woollens, thread, cattle, corn, &c. (Pope (1875) 35,705; (1883) 44,060, of whom 36,751 were Catholices; (1890) 43,013. Münster was known under the name of Minvius by Cæsar in the time of Chârgemagne, who in 791 made it the see of the new bishop of the Saxons, St Ludgerus. Towards the middle of the 11th century a monastery (whence Münster) was founded on the spot, and by 1180 it had grown into a town. In the 12th century the bishopric was elevated to the archbishopric of Münster by Charlemagne, who in 791 made it the see of the new bishop of the Saxons, St Ludgerus. Towards the middle of the 11th century a monastery (whence Münster) was founded on the spot, and by 1180 it had grown into a town. In the 12th century the bishopric was elevated to the archbishopric of Münster by Charlemagne, who in 791 made it the see of the new bishop of the Saxons, St Ludgerus. Towards the middle of the 11th century a monastery (whence Münster) was founded on the spot, and by 1180 it had grown into a town. In the 12th century the bishopric was elevated to the archbishopric of Münster by Charlemagne, who in 791 made it the see of the new bishop of the Saxons, St Ludgerus.

**Munipore.** See MANIPUR.

**Munro, Hugh Andrew Johnston, Latin scholar, born at Elgin in Scotland in 1810, was educated at Shrewsbury, St. Paul's College, and Cambridge, elected fellow of his college in 1843, and professor of Latin in his university in 1860 (he resigned the chair in 1872), and died at Rome, 30th March 1885. His greatest achievement was an edition of Lucan's (1884; 4th ed. 1885), text, translation, and notes, one of the finest and most brilliant works of British scholarship. His Horace appeared in 1869; his Criticisms and Elucidations of Catullus in 1878; and his translations into Latin and Greek of Cicero's works. **Munro, Sir Thomas (1761–1857), son of a Glasgow merchant, was educated at the Glasgow grammar school and university, arrived as an officer in the H.E.I.C.S. at Madras in 1780 in time to serve in the operations against Hyder Ali in 1780–83, assisted in the reorganisation of Mysore, administered Coromandel, and introduced the ryotwari system of tenure, subsequently extended to most of Madras and Bombay. In 1807–15 he was in England, where he had great influence on Indian legislation. Having commanded in the second Mahratta war, he was in 1819 named governor of Madras; but he was soon superseded by Sir John Johnstone, the hero of Albuhera. He returned to England in 1821, held military appointments at home, and spent his last years in improving his estate at Novar.**
small portion being apportioned to Oldenburg, while Hanover acquired the territories of the mediatised Dukes of Arnsberg. The bishopric was reconstituted in 1521. See works by Erhard (1837), Cornelius (1855–60), Keller (1880), and Detten (1887).—There is another Münster in Alsace, 12 miles SW. of Colmar by rail; pop. 3390.

Münster, Sebastian, scholar, was born at Ingelheim in the Palatinate in 1489, studied at Heidelberg and Tubingen, and became a Franciscan monk, but at the Reformation he embraced the new doctrines (1529). He then taught Hebrew and theology at Heidelberg, and from 1536 mathematics at Basel, in which city he died on 23d May 1532. He brought out the first Hebrew Bible (1534–35) edited by a German; wrote Cosmographia (1544), a work on geography that kept its ground for more than a century; and published a Hebrew grammar, a Chaldaic grammar (1527), and lexicon (1527), and a Latin-Greek-Hebrew dictionary (1530).

Muntjak (Cervulus muntjac). These small deer, of which there are several species, appear to connect the true deer with the Cervine (q.v.), as they inhabit the forest tracts of the oriental region—i.e. India, China, Java, Sumatra, Formosa, and the Philippines. The males have large canine teeth as in the Chevrotains; the horns are borne upon a long peduncle covered with hair, which seems to resemble the 'horn' of the giraffe.

Muntz's Metal. See Brass.

Münzer, Thomas, one of the leaders of the Anabaptists (q.v.), was born at Stolberg, in the Harz, about 1489, studied theology, and in 1520 began to preach at Zwickau. His Christian socialism and his mystical doctrines soon brought him into collision with the Reformers and the town authorities. He thereupon wandered through Bohemia, Silesia, and Brandenburg, and settled in Thuringia (1523). Again deprived of his office, he visited Nuremberg, Basel, and other south German cities, and was finally in 1535 elected pastor of the Anabaptists of Mühlhausen, where he won the common people, notwithstanding Luther's denunciations of him, introduced his communitarian ideas, and soon had the whole country in insurrection. But on 15th May 1525 he and his men were totally routed at Frankenhausen by Philip of Hesse. Münzer himself was captured in flight and executed on 30th May at Mühlhausen.

Mura. See Eel.

Mural Circle, an astronomical instrument for the observation of celestial bodies at their meridian passage. It consists of a large and small circle, the latter turning on an axis the end of which projects from a solid stone pier or wall (wherefore the name), close to which the circle moves. The plane of the circle is set as nearly as possible in the meridian. Fixed in azimuthally, the circle is a telescope, which by turning the circle is made to point to the star to be observed, at the time of its meridian passage. Two wires, one fixed and one movable, similar to those in the transit circle (q.v.), enables the altitude, or zenith distance, of the star to be noted, if the instrument has been properly adjusted, and if the zenith or horizontal point on the circle be known. On the rim of the circle are divisions in degrees, &c., so that the angle through which it is turned can be noted by means of several microscopes, as in the transit circle. The mural circles once in use at Greenwich were six feet in diameter, and each degree of the division on the circle is thirtieths of an inch in length. The manner of support allowed of a large circle, which gave this advantage. The mural circle is now almost obsolete, modern improvements enabling all its work to be much better done by the transit circle.

Mural Decoration dates from very ancient times. The Egyptian and Etruscan monuments form an integral and important part of the history of Painting (q.v.), and have helped to mould the development of certain styles of art (see ARABESQUE). Incised work and reliefs have been largely employed. The Greeks tinted their temples and 'picked out' their sculptured friezes and pediments with colour; coloured bricks were used in Assyrian, and wall tiles in Persian, and Pottery in the Eastern nations. Some of the Roman walls were built of tufa and red brick, coloured brick, terra-cotta, and variegated arrangements of marble were largely used in Italy. The plaster-work known as Sgraffito (q.v.) is especially adapted for this use. Many tangential colours on the medallions or medallions, and some were built of flint and stone, and much Tudor work of parti-coloured brick. Distemper and Fresco are described in separate articles; water glass is a silicate process of which there is an example in the Houses of Parliament. Mosaic-work is extensively used in floors and ceilings, but also occasionally employed in mural decoration. The dado of the Albert Memorial Chapel at Windsor is composed of slabs of inlaid marble hatched with coloured gold cement. See also TAPESTRY, WALL-PAPEL.

Another system is that known as Encaustic Painting (Gr. encaustiké, 'fixed by fire'), a manner of mural painting with a medium composed principally of wax, practised by the ancients. As the name implied that fire was used in the execution, some have been led to suppose that encaustic painting is identical with enamelled painting, but noticing by Pliny and other writers show clearly that it was a species of painting in which the chief ingredient used for uniting and fixing the colours was wax dissolved by heat. Various attempts have been made in modern times to revive it. About the middle of the 18th century Count Caylus and Bachelier, and in 1792 Mrs Hooker of Rottingdean, under the name of Emma Jane Greenland, made various successful experiments with this view. Encaustic painting was again taken up in Germany under the patronage of Louis I. of Bavaria, who engaged Schnor (1718–1771), a German, to execute a series of historical subjects on the walls of the royal palace, Munich. For preparing her medium Mrs Hooker dissolved gum-arabic in water, afterwards adding gum-mastic, which was dissolved by stirring and boiling, and when the mixture had reached the right temperature she put in the wax. After painting the picture, she passed a thin coating of melted wax over it with a hard brush, and then drew over the surface an iron—for ironing linen—moderately heated. After the picture cooled it was rubbed with a fine linen cloth. This method was afterwards adopted, but some other ingredients are used; among these, potash with the wax; and, in place of an iron being passed over the surface, the wax is brought to the surface by a vessel containing fire being held at a
little distance from the picture. It is also possible to employ a medium made of a mixture of turpentine and beeswax sufficiently plastic to be worked like oil. A modification of the system was also devised by Mr Gumbler-Parry, and is known as Spirit Fresco. By his method the walls are coated with wax and gum compounded with spirit of lavender. The colours are ground with the same medium.

Murano, famous as the seat of the Venetian glass manufacture, is an island and town a little more than a mile north of Venice, with 3000 inhabitants. It possesses a fine 12th-century cathedral, and another church with some valuable pictures, including Paul Veronese’s ‘St Jerome in the Desert.’ But the chief interest centres in the glass factories—an industry established in the 13th century, and revived in 1680 by Antonio Salvati (1816-90).

Murat, Joachim, king of Naples, was the son of an innkeeper at La Bastingue-Fortuniae, near Cahors, in France, and was born 25th March 1771. He was at first intended for the priesthood, but the outbreak of the Revolution fired his enthusiasm; he enrolled himself in the royal guard, and soon was colonel. Attaching himself closely to Bonaparte, he served under him in Italy and in Egypt, distinguishing himself in many battles; rose to the rank of a general of division (1799); returned with Bonaparte to France, and rendered him most important services during the campaign at Trafalgar. He was chosen co-general of the Council of Five Hundred at St Cloud. Bonaparte now entrusted him with the command of the Consular Guard, and gave him his youngest sister, Caroline, in marriage. Murat held his usual post, the cavalry, and was made colonel. He covered himself with glory, and in 1801 was nominated governor of the Cisalpine Republic. On the establishment of the French empire he was made a grand-duke of Berg (q.v.). He was also regarded as the conqueror of Corsica, which he secured, and paid him homage.

The other Murano was known as a prison, and was used by Napoleon for his political enemies. The island was finally ceded to Austria by the Treaty of Vienna in 1814. It was the residence of the Muratori family, who added much to the knowledge of Numismatics.

Murchison, Sir Roderick Impey, geologist and geographer, was born at Tarradale, Ross-shire, 19th February 1792. He was educated at the grammar school of Dunfermline, and the Military College, Great Marlow. He entered the army at an early age, served as an officer in Spain and Portugal, and was present at Vimeiro and the retreat to Corunna. Quitting the army in 1816, he devoted himself to science, especially geography, and travelled in various parts of the globe. He found the same sedimentary strata lying in the earth’s crust beneath the old red sandstone in the mountainous regions of Norway and Sweden, in the vast and distant provinces of the Russian empire, and also in America. The result of his investigations was the discovery and establishment of the Silurian system, which won for him the Copley Medal of the Royal Society, and European reputation as a geologist. His subsequent exposition of the Devonian, Permian, and Laurentian systems increased the interest he excited. He sailed from Trieste to the Gulf of St Lawrence in 1821, and Helfert (Vienna, 1878).—His widow (1782-1839) assumed the title of Countess of Lipon, and resided in the neighbourhood of Trieste till her death. His two sons went to the United States, wherein the eldest, Murchison, a lawyer (1801-47), settled in Florida, married a niece of Washington, and published Exposition des Principes du Gouvernement Républicain en Amérique (1833). The younger,
of and of the Regional Geographical Society in 1844-45, was re-elected in 1857, and continued to hold that post till 1870, when he was compelled to resign it by the necessity of raising funds to promote geographical science at home, and kindle the spirit of adventure among those engaged in Arctic exploration on the one hand and African discovery on the other. In 1855 he was made director-general of the Geological Survey and director of the Royal School of Mines, which duties he pursued with great success and enterprise, and did much to promote geographical science at home, and kindle the spirit of adventure among those engaged in Arctic exploration on the one hand and African discovery on the other.

MURDOCK. The law presumes that every one who has killed another has murdered him, unless there are circumstances in the case which raise a reasonable doubt that the murderer is punished by death, manslaughter by penal servitude for life, or by a fine, according to the degree of culpability involved in the crime. The law of Scotland does not substantially differ from that laid down by Sir James Stephen, the principal author of the Criminal Law of England (1879). He established a striking instance of regional metamorphism on a large scale. He was a vice-president of the Royal Society, and a foreign member of the French Academy, was knighted in 1860, and created a baronet in 1863. In 1870 he founded the chair of Geology in Edinburgh University. He died 22d October 1871. Most of his contributions to science appeared in the Transactions of the Geological and other Societies. His principal works were The Silurian System (1822), The History of Russia in Europe and the Ural Mountains (1845; 2d ed. 1853). See Life by Professor Arch. Geikie (1875).

Murcia, an ancient town of Spain, on the left bank of the Segura, by rail 46 miles SW. of Alicante and 50 N. by W. of Cartagena. It stands in the productive valley of Murcia, an old-fashioned Moorish town, embosomed in gardens of mulberry, orange, fig, palm, and other fruit trees. Almost the only notable building is the bishop's palace and cathedral, this last begun in 1353, but reconstructed in 1521, and surmounted by a fine bell-tower. Silks, salt, petrole, soda, gunpowder, musical instruments, and glass are manufactured; fruit-growing; the preparation of olive-oil, and the weaving of esparto also flourish. Pop. (1877) 81,803; (1877) 88,558. Alfonso X. of Castile took the city from the Moors in 1243; an earthquake almost destroyed it in 1829; and it was captured by the insurgents in 1843. —The province of Murcia has an area of 4478 sq. m. and pop. (1857) of 491,438. Along with the present province of Albacete it was an independent Arab kingdom for 27 years in the 13th century.

Murder is the unlawful and intentional killing of a human being by a human being. The most comprehensive statement of the distinctions drawn by the law of England between murder and manslaughter is given by Sir James Fitzjames Stephen in an article 223 of his Digest of the Criminal Law. He says: "Manslaughter is an unlawful homicide committed by the act of the offender, without malice aforethought; Malice aforethought means any one or more of the following states of mind preceding or co-existing with the act or omission by which death is caused, and it may exist when that act is premeditated: (a) an intention to cause the death of, or grievous bodily harm to, any person, whether such person is the person actually killed or not; (b) knowledge that the act which causes death will probably cause the death of, or grievous bodily harm to, some person; (c) an attempt to commit any felony whatever; or (d) an intent to oppose by force or violence the apprehension of the offender; or (e) returning from the execution of the duty of arresting, keeping in custody, or imprisoning any person whom he is lawfully entitled to arrest, keep in custody or imprison, or the duty of keeping the peace, or dispersing an unlawful assembly, provided that the person killed is such an officer so employed; or (f) if the act of killing is done in the heat of passion caused by provocation, it is not murder, but manslaughter.

The provincial province of Murcia has an area of 4478 sq. m. and pop. (1857) of 491,438. Along with the present province of Albacete it was an independent Arab kingdom for 27 years in the 13th century.
by circulating water through pipes; a method of sending messages through an exhausted air tube; and many other inventions. His investigations in the distillation of coal-gas began at Redruth in 1792, when he lighted his offices and cottages by its agency. He publicly showed the results in 1797 and in 1798, the premises at Soho being lighted with gas. But he did not reap due profit from this; and continued his invention. He died 15th November 1839. See a life of him by his kinsman Alexander Murdoch (1892).

Mure, Sir William, of Rowallan in Ayrshire, Scottish poet, was born in 1594, a nephew of the author of The Cheere and the Shie. He was wounded at Marston Moor, and died about the end of 1667. He translated into English Sappho of Trophig's Latin poem, Hecatoboea Christiana; but his principal work is his True Crucifixe for True Catholicks (Edin. 1629). His fine version of the Psalms dates from 1639. See the Scottish Text Society's edition of his poems (2 vols. 1856).

Mure, William, was born at Caldwell in Ayrshire in 1796, educated at Westminster and the universities of Edinburgh and Bonn, represented Renfrewshire 1846–55, was Lord Rector of Glasgow University 1847–48, and died in London, 1st April 1890. Colonel Mure was for many years commandant of the Renfrewshire militia. He was the author of A Critical Account of the Language and Literature of Ancient Greece (5 vols. 1850–57), a work of sound scholarship and great learning; he maintains the unity of the Homeric poems. Mure also wrote Journal of a Tour in Greece (1842) and a couple of treatises on Egyptian chronology.

Muret (Murets), Marc Antoine, a celebrated humanist, was born at Muret, near Limoges, 12th April 1596. In early life in France he read lectures on civil law with great success, but subsequently in Italy he seems to have devoted himself entirely to literature till 1578, when he took orders. He afterwards resided in Rome till his death, 4th June 1585. His well-known Orationes, though shallow, are remarkable examples of eloquence in the style of Cicer. His poems, Latin and French, though graceful and fluent, are now considered worthless; but his learned criticisms and commentaries, Variae Lectiones, in 3 books, are held in great estimation. There are editions of his works by Ruhnken (1759) and Frotscher (1834–41), and 2 vols. of Scripta Selecta (1751–73) by Frey. See also the monograph by Dejob (Paris, 1881).

Murex, a genus of marine Gastropods in the same set as the Snails, cone-shells, and cowries. The members prey upon other molluses, boring by means of the usual rasper. The shells are fringed

Murgeon, Henri, novelist and poet, was born in Paris on March 24, 1822. He began his life as a notary's clerk, and afterwards acted as secretary to Comte Tolstoi, at a salary of about a pound a week. He gave himself to literature, and for several years led the life of a retired and adventurous poet, which he has described in his Scenes de la Vie de Boheme (1845). At last his genius was recognised by Arsène Houssaye, the editor of the Artiste, and during his later years his popularity was secure. Every journal was open to him, but he wrote slowly and fitfully in the intervals of dissipation, and was never in easy circumstances. He died in the hospital in Paris on January 28, 1861. His first and best novel, Scenes de la Vie de Boheme, is, says Mr Saintsbury, a work final and perfect, which preserves a place in the literature of humanity. A vivid translation of the score and jocund, of the writer's years of struggle, it is in parts infinitely pathetic, in parts irresistibly amusing. Murger had a rich gift of humour, but his predominant tone is one of poignant melancholy. Le Manech de Fervençons is one of the saddest, as it is one of the most beautiful, short stories ever penned. He had uncommon literary skill, and could portray certain types of character admirably. But he had only one subject which he could handle successfully—the Bohemian of literary Paris. Next to the Scenes de la Vie de Boheme, his best works are Scenes de la Vie de Jeunesse, les Buvards d'Eau, and the short tales included in the volume entitled Madame Olympe. His poems, Les Nuits d'Hiver, are graceful, sincere, and often deeply pathetic, bearing strong traces of the influence of Musset. One of them, La Chanson de Muzette, is a lyric masterpiece—"a tear," said Gautier, "which has become a pearl of poetry." Several of Murger's pieces have been translated with rare felicity by Mr Andrew Lang in his Lays of Old France. Murger was the author of Derriere Devouzons, Scenes de Campagne, Le Pays de Latin, Le Sabot Rouge, Les Vacances de Camille, &c.

Murger, as the notice of Murger by Gautier, Houssaye, Janin, and Saint-Victor in Les Nuits d'Hiver (1802).

Murghab, a river that rises in the mountains north-east of Herat in Afghanistan, flows north-west, and loses itself in the desert of Turkestan beyond Merv.

Muriatic Acid. See Hydrochloric Acid.

Murdae, a family of rodent quadrupeds, containing many genera and a very large number of species, distributed over all parts of the world, and of which rats and mice may be regarded as typical examples. To this family belong also voles, lemmings, dormice, jerboas, marmots, &c.

Murillo, Bartolomé Esteban, was born of humble parentage at Seville, and baptised January 1, 1618; and, after receiving some education, was placed with his relative, Juan del Castillo, to study painting. Having saved a little money, which he devoted to painting, and, through religious pictures for the fairs of Seville and for favourably noticed by his celebrated townsman Velasquez; and through his influence was enabled to study the chefs-d'oeuvre of Italian
and Flemish art in the royal collections. In 1645 he determined to return to Seville, though advised to proceed to Rome by Velasquez, who offered him letters from the king. After settling in Seville, he painted eleven large and remarkable pictures for the convent of San Francisco. In 1658, on the completion of two famous pictures for numerous important commissions, was soon acknowledged as the head of the school there. In 1618 Murillo married a lady of fortune; he now maintained a handsome establishment, and his house was the resort of people of taste and fashion. About this time he passed from his cool cold style—stark with decided outlines—to his second or 'warm' style, in which the drawing is softer and the colour improved. Of the second style good examples are 'St. Leander,' the 'Nativity of the Virgin,' and 'St. Antony of Padua.' In 1656 he was engaged on four great semicircular pictures, which are the first examples of his third or 'vaporous' manner, the outlines vanishing in a misty blending of light and shade. The three styles, it should be said, are not strictly chronological, the warm style constantly reappearing, whenever he felt that a subject lent itself to it, in 1650, but he filled the office of president only during the first year. After this came Murillo's most brilliant period; eight of the eleven pictures painted in 1651-74 for the almshouse of St Jorge, including 'Moses striking the Rock,' 'Abraham and the Angels,' 'The Miracle of the Loaves and Fishes,' 'St Peter released from Prison,' and 'St Elizabeth,' are accounted his masterpieces. He executed some twenty pieces for the Convent of Conception at Seville in 1675. He frequently chose the Immaculate Conception or Assumption of the Virgin as a subject unmarred by human features, during his residence in the Louvre was sold in 1822 at the sale of Marshal Soult's pictures for £24,000. In 1681 he went to Cadiz, and while there fell from a scaffold when painting an altarpiece in the church of the Conceptionists, returned to Seville, and soon after died from the injury he received, April 3, 1682. Murillo's pictures naturally fall into two great groups—scenes from low life, Gypsies and beggar children (mostly executed early in his life), and scripture and religious works. Of the former, by which he is largely known abroad, only a few are to be met with. Though his best pictures show much technical skill, truth to nature, and sentiment of a kind, they seldom show ideal beauty or subtlety of feeling.

See Miss E. E. Minor's Murillo ('Great Artists' series, 1882), and E. C. Curtis's Velasquez and Murillo (1883), the latter giving a list of 481 pictures by Murillo—105 in London, 99 elsewhere in England, 61 in Madrid, 59 in Seville, 21 in Paris, 24 in Russia, &c.

**Murphy, Arthur**, dramatic and miscellaneous writer, was born in Roscommon, Ireland, in 1727. Intended by his father for business, he was placed in London, and having received his education at the college at St Omer, in France, made extraordinary proficiency in Greek and Latin, he contrived literary and dramatic tastes. In 1762-74 he published the *Gray's Inn Journal*, a weekly paper which obtained him the acquaintance of Dr Johnson. Being disappointed of some expectations and already in debt, he went on the stage, and made his first appearance as Othello. In one season he paid his debts, and then left the stage with £400 in his pocket; and, determining to study law, he entered Lincoln's Inn in 1757. In 1759 he published *The Upstart* (a successful farce; in 1762 he was called to the bar, but with so poor a result that in 1778 he retired. He continued to write comedies and other plays for the stage, and is said to have produced more stock pieces than any man of his time. His translation of Tacitus (1793) is excellent; but his *Essay on Johnson and Life of Garrick* did not add to his fame. His dramatic works fill 8 vols. Late in life he became a Commissioner of Bankruptcy, and enjoyed a pension of £200 a year. He died in 1803. See his Life by Jesse Foot (1834).

**Murray**, in the medical term loosely used to designate a variety of diseases of domestic animals, but more generally restricted to the vesicular epi- zootic, popularly known as the foot-and-mouth disease. It is a contagious, infections eruptive fever, affecting cattle, sheep, pigs, and poultry; but is rarely observed in this the disease is characterized by the appearance of little bladders or vesicles in the mouth, on the lips, gums, and tongue, on the corneal and interdigital spaces of the feet, causing inability to eat, driving off of saliva, sometimes heat and swelling of the udder, and lameness. The disorder runs a fixed and definite course usually in eight or ten days. Good nursing, comfortable lodgings, and a liberal supply of soft, easily digestible food, are the chief requisites for speedy recovery. A laxative may be given if needed. The mouth may be washed out twice daily with hot weak lime water. The udder must be made with half an ounce of alum, oxide of zinc, or sugar of lead, to the quart of water. When the udder in milch cows, in which the complaint is usually most serious, is affected, it should be bathed with tepid water before and after milking, which must be attended to in the most scrupulous manner; the udder may then be washed with water, or a clean, loose born removed, and washed occasionally with the lotion used for the mouth. See also *Anthrax*, *Cattle-plague*, *Pleuro-pneumonia*.

**Murray, Alexander**, philologist, was born the son of a shepherd in the parish of Munnigaff, Kirkcudbright, 22d October 1753, and had hardly any conception save what his father could impart, till 1768, when he was at school for a short time. Yet by diligent and omnivorous reading of all such books as fell in his way or could be borrowed, he, when engaged as a shepherd, acquired, besides a scholarly knowledge of English literature, a mastery of the classics, all the principal European tongues and Hebrew. The fame of the learned shepherd led to an invitation to Edinburgh, where he obtained a bursary, gave private lessons, and continued his linguistic labours, which were extended to oriental tongues and ancient and modern Abyssinian. In 1806 he became minister of the English Church of Glasgow, and in 1807 professor of Oriental Languages in Edinburgh University; but he died 15th April 1813. His *History of the European Languages* was published in 1823.

**Murray, David Christie**, novelist, was born 13th April 1847, at West Bromwich, in Staffordshire, and had served as reporter and then as war-corre- spondent (1877-78) for several newspapers, when in 1879 he published A Life's Atone ment in *Chamber's Journal*. In the same journal appeared *Val Strange and John Vale's Guardian*. Other works are *By the Gate of the Sea*, *The Way of the World*, *Aunt Rachel, Old Hobber's Hero*, *The Weaker Front*, and *Dennison's Demure*. In 1889 he visited Australia and went on the stage.

**Murray, Eustace Clare Grenville, the 'Roving Englishman,' was born 2d October 1819, the natural son of the second Duke of Buckingham. After studying at Oxford, he served till 1849 in the Austrian army; in 1851 joined the British embassy at Vienna and Wallachia; in 1854 went on a mission to the islands in the Aegean Sea; in 1857 was attached at Teheran; and in the next year counsel-general at Odessa. For exposing in the public press in 1866 certain abuses connected with the foreign office he was dismissed the service. He spent the rest of his life in Paris, and died at Paris, on 26th December 1881. As a journalist he is best known for his
brilliant papers in the Daily News and Pall Mall Gazette, and as an author by The Roving Englishman (1854-55), Embassies and Foreign Courts (1855), History of the French Press (1874), Men of the Second Empire, etc (1872-74), and a few brilliant novels. Of the last, The Member for Paris (1870) is the best known, but Young Caesar (1874), from the circumstances of its hero's birth, has the most interest.

Murray, James A. H., philologist, was born at Denholm, Roxburghshire, in 1837, received his elementary education at Minto school, removed to Hawick, and was appointed assistant-teacher in the parish school there, and afterwards master of the same, and in 1852 removed to London, filling the post of foreign correspondent in the Oriental Bank for some years; he afterwards became senior assistant-master at Mill Hill school. Dr Murray has been twice president of the Philological Society (1879-80), is a graduate of London University, and L.L.D. of Edinburgh University. His work on the Dialects of the Southern Counties of Scotland (1873) established his reputation as a philologist. He is familiar with almost all the European languages and a large number of oriental tongues. The great work of his life was the establishment of the Oxford University Dictionary of the English Language, a work of 4,125 pages, and completed in 1853. His Dictionary of the English Language, with Shorter Dictionary of the English Tongues, containing about 100,000 words, and his great English Dictionary is the most thorough and important work of the kind ever undertaken in Britain. A civil list pension of £270 per annum was conferred upon him in 1884.

Murray, John, the name of four generations of English publishers, will for ever remain associated with the pleasantest days of English literature in the 18th and 19th centuries. The founder of the house was John Murray I, who was born in London in 1745. He obtained a commission in the Royal Marines in 1762, and in 1768 was second-lieutenant, when, disgusted with the slowness of promotion, he purchased the bookelling business of John and James Dods of the Strand, London, and, dropping the Scottish prefix, became a bookseller and publisher. He brought out the English Review, and published the first two volumes of the elder Dods's Curiosities of Literature, &c. He died November 16, 1783, and was succeeded in due time by his son John (born November 27, 1776), a minor of fifteen at his father's death, who was for a short time associated as partner with his father's shopman, Mr Highley. One of the earliest hits of John the second was Mrs Ruddell's Cookerybook, of which over 300,000 copies were sold. He became connected with Mr Stratford Canning, afterwards Lord Stratford de Redcliffe, through the assistance he lent him and other Etonians— with their publication of The Miniature. In 1808-9 he projected the Quarterly Review, a Tory organ, in opposition to the Edinburgh Review; his first step being to obtain Canning's connessionate. A severe criticism of Scott's Marmion in the Edinburgh Review suggested to Murray a visit to Scott; he secured his co-operation, as also that of Heber, Canning, George Ellis, and Sir John Bowes. The London Magazine, the Edinburgh Review, and the Monthly Magazine, under the editorship of William Gifford. The new periodical was completely successful, attaining a circulation of 18,000 copies, and brought Murray into communication not only with the chief literary men, but also with the Conservative statesmen of the time. A still more fortunate connection was that with Lord Byron (1819), whom he offered £600 for the first two cantos of Childe Harold (published 1812). Murray was removed from Fleet Street to Albemarle Street, where the business of the family was still carried on. Here Byron and Scott first met, and here Southey made the acquaintance of Crabbe. Almost all the literary magnates of the day were 'four o'clock visitors' in Albemarle Street—wits and harpies; Crabbe, Campbell, Croker, Fores, and Wards,' Murray said. By 1825 nearly £10,000 for his works, and his dealings with Crabbe, Moore, Campbell, and Irving were prudently. He had at one time dealings with Constable and Ballantyne, but never approved of their methods of business. Hearing that Byron was in difficulties in 1815, he sent him a cheque for £1,500, promised munificence for the same amount, and even offered to sell the copyright of his works on his behalf if necessary. (As to Byron's autobiography, see Byron, Vol. II, p. 588). Perhaps his only unsuccessful venture was the Represser of Crime (1826), paper; his 'Family Library' was begun in 1829, and he issued the travels of Mungo Park, Belzoni, Parry, Franklin, and others. The second John Murray died in his sixty-fifth year, June 27, 1843, and was succeeded by his son, John Murray the third, born in 1808, and educated at Edinburgh University. A more practical and realistic age had succeeded that of Byron, and the 'Home and Colonial Library' was the precursor of much of the cheap railway and other literature of the present day. Many of the greatest works in history, biography, and travel have been issued by the third Murray. Among his successors may be mentioned Dr Livingstone's Travels and Last Journals, Smiles's Life of George Stephenson, Self-help, of which more than 150,000 copies have been sold, Darwin's works, Dr Smith's dictionaries, and the well-known handbooks for Travellers (begun 1836; see Guidebooks), of the first five of which he was author. He died April 2, 1892, when his son, the fourth John Murray, became head of the firm. See S. Smiles, A Publisher and His Friends (1891).

Murray, John (1741-1815), was the founder of Universalism (q.v.) in America.

Murray, Lindley, grammarian, was born at Scituate, Massachusetts, in 1745, the eldest of twelve children, and was educated at school in Philadelphia belonging to the Society of Friends. On his father's removal to New York he was placed in a counting-house, but his thirst for study was so ardent that he escaped to a school in New Jersey. He then studied law, and was admitted to the bar at the age of twenty-one, and commenced a good practice. During the revolutionary war he engaged in mercantile pursuits with such success as to accumulate a handsome fortune. In 1784, his health failing, he came to England and purchased a estate at Holigiate near New York, where he devoted himself to literary pursuits. In 1787 he published his Power of Religion on the Mind, which passed through nineteen editions, and was translated into French. His Grammar of the English Language (1796), and was followed by English Exercitations, the Key, the English Reader, Introduction and Sequel (both translated into French), A Spelling Book, A First Book for Children, A Compendium of Faith and Practice, and The Duty and Benefit of a Daily Renewal of the Soul, passed through numerous large editions, and there can be no stronger indication of how entirely the
systematic study of the English language had been, until recent years, neglected by scholars than the fact that Murray's Grammar was for half a century the standard textbook throughout Britain and America. Murray wrote an autobiography in the year 1809, which was published after his death, February 10, 1812.

Murray, the Resident. See Moray.

Murray River, the principal river of Australia. It rises in the Australian Alps, flows north-west along the frontiers of New South Wales and Victoria, and in South Australia passes southward through the shallow Lake Alexandrina towards the sea at Encounter Bay. In its 1,125 miles' length it is navigable for small steamers as far as Albury, 190 miles NE. of Melbourne, but its mouth cannot be entered by ships of any size. The chief tributaries are the Lachlan and Murrumbidgee and the Darling (q.v.), themselves large rivers. See also Australia, New South Wales, Victoria.

Murschelbad, a town of India, situated on the left bank of the Biagirathi, a branch of the Ganges, 124 miles N. of Calcutta. During the 18th century it was the capital of Bengal and a very populous city; but about the time (1790) the British made Calcutta their headquarters Murshelbad began to decline. Pop. (1851) 39,231; (1891) 35,576. The chief buildings of note are the palace of the Nawab (1837), the Imámábāda ("house of prayer"), and a mosque. Two miles south of the city is Motijhil or Pearl Lake; on its bank stands the house of the Nawab, in which Clive enthroned Mir Jafar, and the English Residents—Warren Hastings the first—dwelt.

On the opposite side of the river is the old cemetery of the Nawabs, containing a musoleum, mosque, &c. The city is noted for its ivory-carving, its embroidery in gold and silver lace, silk-weaving, and the manufacture of hookah pipes and musical instruments. It is moreover a busy centre of trade. The district has an area of 21,44 sq. m., and a pop. (1881) of 1,226,790; (1891) 1,250,946.

Murten, battle. See Morat.

Murville, a town of Spain, 18 miles NNE. of Valencia, stands on the site of the ancient Sabrata and Sax, the scene of which by Hannibal (q.v.) was the beginning of the second Punic war. Pop. 6287.

Muruz, See Fezzan.

Musaceae, a natural order comprising the largest of herbaceous plants, generally destitute or almost destitute of true stems, yet resembling trees in appearance, and sometimes rivaling palms in stateliness, the long shathing bases of the leaf-stalks combining to form a false stem. The blade of the leaf has many fine parallel veins proceeding from the mid-rib to the margin. The flowers are congregated on spadix, which are protected by spathes. The fruit is either a 3-valved capsule or fleshy, and is not generally noticed under textile purposes (see Banana, Abaca, FIBROUS SUBSTANCES). A very interesting plant of the order Musaceae is the Traveller's Tree (q.v.) of Madagascar.

Musceae, one of the ancient mythical poets, seers, and priests of the Greeks, is said to have been the son of Eumolpus and Selene, or, according to others, the son and pupil of Orpheus. He was the reputed author of a number of poems, oracles, prophetic verses, hymns, &c., of which we possess but a few fragments, and those of doubtful authenticity.—A later Muscaeus, who flourished about the end of the 5th century, was the author of a beautiful little poem in Greek, entitled Hymni ad Deos Mercatorum (489; by Ditleff, Bonn, 1874). See Hetro.

Musa ibn Nasair (born 640), the Arab conqueror of northern Africa (699-709) and of Spain (712), fell under the displeasure of the Caliph of Damascus, and died in poverty in Hedjaz in 717.

Musaeus, Johann Karl August, a German writer, born on 29th March 1733, at Jens, where he studied theology. In 1763 he was appointed tutor to the pages at the ducal palace of Hanover, and in 1770 became Professor of Greek at the gymnasium. His first production in 1769 was a parody of Richardson's Sir Charles Grandison, a book at that time extravagantly admired in Germany. Eighteen years later he satirized Lavater in Physiognomische Reisen. But his literary fame rests upon his version of Volckmärchen der Deutschen, which professed to be a collection of popular tales noted down from the lips of old people; but such is not exactly the case: their chief note is an artificial naïveté. Nevertheless, they are tinctured with such a sense of moral satire, and so graceful and graceful writing that they have become a classic of their kind. He continued to work the satirical vein in Freund Hein's Erziesungen in Holbein's Manier (1785), and began a course of tales, Sturmsseldern (1787), which he did not live to complete. He died at Weimar, 28th October 1787. See Life by M. Müller (1867) and Ad. Stern in Literatur-fragmente (1893).

Musae Volantenes is the term applied to ocular spectra, which appear like flies on the wing, or floating black spots before the eyes. There are two kinds of musae volantenes—the one a perfectly harmless kind, while the other is symptomatic of some disease of the eyes. Whoever will look through a minute pin-hole in a card at the clear sky may see floating before his sight a number of translucent tubes or fibres, and many little heads, of which some are separate, some attached to the tubes, and some apparently within them. Some of the tubes or fibres are straight, others looped or twisted, and others again forked. All these objects are bright in the middle, and bordered by fine black lines, beyond and parallel to which may be seen an appearance of coloured lines or fringes. The double crossings in the twisted fibres appear as black points. Though the eye be fixed, these bodies change their position with greater or less rapidity. These appearances are produced by the shadows of minute corpses and fibres present in the vitreous humour. They are not generally noticed under ordinary conditions; but some persons, especially those who have small pupils or who are short-sighted, readily see them, especially on looking at a bright surface, such as a white cloud or a brightly-illuminated sheet of paper. If attended to and watched they become more prominent, and may cause a good deal of annoyance. When they become visible and troublesome under ordinary conditions they generally indicate some defective state of health, particularly of the digestive organs. The appearance of dark spots before the eyes not infrequently, in people who believe themselves to be free from any disease, is due to the existence of a diseased condition of the deeper parts of the eye, vitreous humour, retina or choroid; and as these, or the morbid conditions causing them, are almost always visible with the ophthalmoscope, the eyes should be thoroughly examined in any doubtful case (see Eye, Ophthalmoscope). For further information on the differences between the innocent and the dangerous
forms of muscle volitantes, the reader is referred to an article by Sir David Brewster in the North British Review for November 1856.

**Muscardine** or **Silkworm Rot** (*Botrytis Bassiana*, so called from the Italian physician Bassiana, who first pronounced it to be a disease in 1834), is a mould doubtless belonging to the Discomycetes (since its congener *B. cinerea* has been shown to be the spore-bearing phase of *Peziza Fuscoclavata*). It was first observed on the silkworm in Piedmont and France in the later part of the 18th century, and was first described in the first half of the 19th, but has since been practically stamped out. De Bary has shown that it occurs not unfrequently upon a variety of insects.

**Muscat**, or more correctly **Maskat**, capital of the independent state of Oman or **Muscat**, which occupies the south-eastern corner of Arabia. It stands in a narrow rocky cove that opens out to the Indian Ocean, on the one side, and to the other forms the exit of a pass leading from the interior of Arabia. It is surrounded by a wall, and defended by forts planted on the rocky heights above. Its streets are narrow and not over clean; in summer the heat is intense; hence Muscat is not a healthy place. Yet the advantages of its situation make it of great importance for the commerce between eastern Arabia, Persia, India, the east coast of Africa, and the Red Sea. Its total trade reaches the value of £1,100,000 annually, the chief exports being pearls and fish, in which its coastal waters are extraordinarily rich, and salt, dates, drugs, dyestuffs, horses, and the imports chiefly coffee, rice, sugar, piece-goods, oil, &c. Pop. about 20,000. Although a very ancient place, Muscat remained small and of little importance until the Portuguese took possession of it in 1508. Under their rule, lasting exactly a century and a half, it developed into a prosperous commercial centre. It was subsequently governed by native rulers (*imans*), who in the 17th century succeeded the Portuguese also as masters of Zanzibar and some places on the east coast of Africa. Many of the present inhabitants were, however, wrested from the reigning imam of Muscat by an illegitimate son in 1856.

**Muscatel** (Ital. *moscato*, ‘musk’), the name given to many sweet, strong French and Italian wines, whether white or red. Amongst the finest are the white Riversaltes and red Bagnol from Provence. In the northern part of Provence, the Lacryme Christi of Naples, &c. Fine varieties are yielded by Syracuse, Sardinia, the Cape, Canary Islands, Corfu, Crete, and Cyprus.

**Muscatine**, capital of Muscatine county, Iowa, is on the west bank of the Mississippi, built mostly on rocky bluffs, where the river makes a great bend to the south, 211 miles by rail WSW. of Chicago. It has a large trade by river and rail, and contains great pork-packing establishments, as well as flour and lumber mills, and plough and furniture factories. Pop. (1880) 11,464 ; (1900) 14,073.

**Muschelkalk** (Ger., ‘shell-line’), the middle member of the Triassic system as developed in Germany. It is wanting in Britain. The muschel-kalk consists chiefly of limestone—the series attaining a thickness of 550 to 1100 feet. The upper portion is more or less pure limestone and highly fossiliferous; the middle and lower portions consist mostly of dolomitic limestone, with which are associated rock-salt, gypsum, and anhydrite. One of the most abundant and characteristic fossils of the muschelkalk is the lily encrinite (*Emericium bifiiforme*). See Triassic System.

**Muscle**, the fleshy parts of an animal. Muscular tissue is specially distinguished by its power of contracting in one direction, and is the instrument by which all the sensible movements of the animal body are performed. When examined under a high magnifying power the fibres of which it is composed are found to exist under two forms, which can be distinguished from one another by the presence or absence of very close and minute transverse bars or stripes. The fibres of the voluntary muscles—those whose movements can be influenced by nerve impulses originated by the will—as well as the fibres of the heart, are striped; while those of the involuntary muscles, such as the muscular fibres of the intestinal canal, of blood-vessels (q.v.), and in skin, are unstriped.

On examining an ordinary voluntary muscle with the naked eye, we observe that it presents a fibrous appearance, and that the fibres are arranged with great regularity in the direction in which the muscle is to act or contract. On closer examination it is found that these fibres are arranged in *fasciculi*, or bundles of various sizes, enclosed in sheaths of areolar tissue, by which they are at the same time connected with and isolated from those adjoining them; and when the smallest *fasciculus* visible to the naked eye is examined with the microscope it is seen to consist of a number of cylindrical fibres lying in a parallel direction, and closely bound together. These fibres may end in blunt extremities or be forked as in the lips, or branched as in the tongue. Each fibre consists of an elastic homogeneous sheath—the *sarcodema* (Gr. *sarx*, ‘flesh’, and *lemma*, ‘a skin or husk’), which contains a semimembranous semi-fluid material. This substance shows transverse striations in the malian muscle at regular intervals, as well as longitudinal strie. Dilute mineral acids cause the fibre to cleave crosswise into discs. When highly magnified the transverse strie resolve them-
Muscles vary extremely in their form. In the limbs the form of considerable length, surrounding the bones and forming an important protection to the joints; while in the trunk they are flattened and broad, and contribute very essentially to form the walls of the cavities which they enclose. Muscles derive their names variously (1) from their situation—as the temporal, pectoral, gluteal; or (2) from the body, muscles as the rectus, obliquus, &c., of which there may be several pairs,—as, for example, rectus femoris, rectus capitis; or (3) from their uses—as the mas- seter, the various flexors, extensors; or (4) from their shape—as the field, trape- zius, rhomboid; or (5) from the number of their divisions— as the biceps and triceps; or (6) from their points of attachment—as the stern-esterno-mastoid, the sterno-thoracic.

The skeleton, which may be termed the locomotive framework, may be regarded as a series of levers, of which the fulcrum is, for the most part, in a joint—viz., at one extremity of a bone—the resis- tance (or weight) at the further end, and the force (or muscle) in the intermediate portion. In most cases, in order to preserve the neces- sary form of the body, muscles are applied at a great mechanical dis- advantage as regards the exercise of their power; that is to say, a much larger force is employed than would suffice, if differently applied, to overcome the resistance. The two main sources of this disadvantage Fig. 7.—Muscular lie in the obliquity of the inser- tions, and consequently of the action. Heart.

Muscles from the of most muscles, and in the muscles being usually inserted very near the fulcrum. The first lever in many cases diminish- ed by the enlargements of the bones at the joints. See fig. 8. A. The tendons (r) of the muscles (m) situated above the joint are usu- ally inserted immediately below the bony enlarge- ment, and thus reach the bone that is to be moved (o) in a direction some- what approaching the perpendi- cular, so that the actual lever of Langenbeck did not exist (as in fig. 8, B), the con- traction of the muscle, instead of causing the lower bone to turn upon the upper one with comparatively little loss of power, would do little more than cause the two ends of the bones to press upon each other. The second mechanical disadvantage is compensated for by gain in the extent and velocity of movement, and by the avoidance of the great inconvenience of having the muscles extended in straight lines between the ends of jointed continuous levers. Thus, the bones of the hand (fig. 9, b, c) are bent upon the bone of the arm (a) by the biceps muscle (d), which arises close to the head of the latter, and is inserted at e, at a short distance from the elbow- joint, which acts as the fulcrum of the lever (e).
MUSCOVITE

this arrangement a contraction of a single inch in the muscle moves the hand (/), in the same time, through the extent of about 12 inches, but then the hand moves through every inch with only about the twelfth part of the power exerted by the muscle. By the junction of two or more levers in one direction, as in the different segments of the extremities, the extent and velocity of their united actions are communicated to the extreme one.

MUSHROOM

Thus, a blow of the fist may be made to include the force of all the muscles engaged in extending the shoulder, elbow, and wrist.

The great and characteristic property of muscular tissue—that of shortening itself in a particular direction when stimulated—is called contractility. The stimulus may be direct irritation by mechanical means, or by galvanism, or by some chemical substance, but in the living body the muscular fibres are, in most cases, made to contract by the immediate influence of the nerves distributed among them, which are consequently termed motor nerves (see NERVOUS SYSTEM), and are under the influence of the will. By an exertion of volition, we can contract more or fewer muscles at once, and to any degree, within certain limits; and, as a matter of fact, there is hardly any ordinary movement performed in which several muscles are not called into play. But every voluntary muscle is also subject to other influences more powerful in their operation than the will. The movements of the features under the impulse of passion and emotion are more or less involuntary, as is shown by the very partial power the will has of restraining them, and the extreme difficulty of imitating them.

Many movements ensue involuntarily when certain impressions, which need not necessarily be attended with consciousness, are made on the surface of the body, or on any part of its interior, either by external or internal causes. Such movements are termed reflex, and are noticed in the article NERVOUS SYSTEM. For various important groups of muscles, see ARM, EYE, FOOT, HAND, KNEE, LEG, &c.; and for the source of muscular force, see DIET, DIGESTION.

Muscovy. See RUSSIA.

Muses, in the Greek Mythology, divinities originally included amongst the Nymphs, but afterwards regarded as quite distinct from them. To them was ascribed the power of inspiring song, and poets and musicians were therefore regarded as their pupils and favourites. They were first honoured amongst the Thracians, and, as Pieria around Olympus was the original seat of that people, it came to be considered as the native country of the Muses, who were therefore called Pierides. In the earliest period their number was three, though Homer sometimes speaks of a single muse, and once, at least, alludes to nine. This last is the number given by Hesiod in his Theogony, who also mentions their names—Clio, the muse of history; Euterpe, of lyric poetry; Thalia, of comedy; Melpomene, of tragic; Terpsea, of horned; Erato, of erotic poetry; Polyhymnia, of the sublime hymn; Urania, of astronomy; and Calliope, of epic poetry. Their origin is differently given, but the most widely-spread account represented them as the daughters of Zeus and Mnemosyne, or as spectators of the Sirens, or goddesses of song, and as dwelling on the summit of Olympus. They are also often represented as the companions of Apollo, and as singing while he played upon the lyre at the banquets of the Immortals. Various legends ascribed to them victories in musical competitions, particularly over the Sirens. In the later classic times particular provinces were assigned to them in connection with different departments of literature, science, and the fine arts; but the invocations addressed to them appear to have been, as in the case of modern writers, merely formal imitations of the early poets.

 Their worship amongst the Romans was a mere imitation of the Greeks, and never became truly national or popular. Among the places sacred to them were the fountains of Aganippe and Hippocrene on Mount Helicon, and the Castalian spring on Mount Erymanthus.

Museum (Gr. museion), originally the name given by the ancients to a temple of the Muses, and afterwards to a building devoted to science, learning, and the fine arts. The first museum of this kind was the celebrated Alexandrian Museum—a meeting-place for learned men and a library, founded about 280 B.C. in the palace. After the revival of learning in Europe the term museum came to be applied to collections of antiquities, and sculptures, and paintings. Collections illustrative of natural history and other sciences now form a chief part of the treasures of many of the greatest museums, and there are museums devoted to particular branches of science, and to illustrating the industrial arts. Of the museums of Britain, the British Museum (q.v.) and that of South Kensington (see KENSINGTON) are the most important. The museums of the Vatican in Rome, of the Louvre in Paris, of St. Petersburg, of Vienna, Munich, and Berlin, and the National Museum at Washington also are among the greatest in the world. See the Address of the President of the British Association, 1889.

Musha Islands. See OBOCK.

Mushroom, or Agaric, the popular name of a somewhat diverse group of genera and species of fungi belonging to the sub-order Hymenomycetes, of the great class Cryptogamae. The best known of the true mushrooms to English readers is the Common Mushroom (Agaricus campestris), and it is the type of the sub-order named. In Britain it is the most esteemed of its tribe, though little valued in countries where fungi more generally form an article of diet of the people; in Italy it is disapproved. It should be noted that some of the forms common to Europe and North America are esteemed in England, but found unpalatable in the United States. The Common Mushroom varies considerably in colour, according to soil and locality, but presents in all its variations the same essential characters. It has a fleshy head or pileus, smooth or scaly on the upper surface, varying in colour from white to different shades of tawny or fuliginous brown. The gills (funiculi) on the underside of the head are free, at first palid, changing by gradations in age to pink, purple, and brown-black. The stem is white, varied in shape, full, firm, furnished towards the top with a white persistent ring. The Common Mushroom is widely
distributed in most of the temperate regions of both the northern and the southern hemispheres. In Britain it is abundant chiefly in autumn in pastures and orchards. — The Horse Mushroom (A. arvensis) is very frequently found growing in company with the Common Mushroom. It is altogether a coarser and larger form, and is less favoured for culinary purposes except in the making of ketchup. It often attains enormous dimensions; the top is generally smooth and snow-white, gills brownish white, ultimately with age becoming brown-black, stem pithy or hollow, with a ragged or floccose ring. This is the 'White-caps' Mushroom of some parts of England. — The true St George's Mushroom (A. ambrosia of some, or primulosus of others), so called from appearing about St George's day (April 23), is sometimes confounded with the Common Mushroom. The head is thick and fleshy, at first convex, becoming undulated and irregular in outline, light yellow in colour in the centre, fading to opaque white at the edges, gills yellowish white, irregularly interposed, smaller and larger, overlying each other like the plait of a frill; the stem is solid, white, when young bulging at the base, but in age either equal throughout or tapering to greater thickness above. The skin of this mushroom is soft and firm to the touch, and in appearance has been aptly described by Berkeley as resembling a crackled biscuit. It is one of the most prized of the Agaries on the Continent, so much so in Rome that a dish of it is considered the most fitting present to any one whose good offices are to be propitiated.— The Fairy-ring Mushroom (A. oreutis; Marasmius oreutis of some), also the Champignon of the French, is common in pastures and in lawns in Britain, and in most parts of Europe. The head is small, smooth, fleshy, convex, having a boss (umbo) in the centre, tough, leathery, elastic, wrinkled; when soaked with water brown, when dry buff. The gills are free, distant, somewhat paler than the head; the stem equal in thickness, twisted, tough, fibrous, of a pale silvery-white colour. This species is much esteemed by all who know it. Its flavour is extremely fine, and it is employed in the making of the best kinds of ketchup. On the Continent it is dried and used in the form of a powder to flavour various made dishes. Its peculiar mode of growing in circular patches or in rings, which procured for it its popular name, leads to the risk of an

allied but poisonous species which sometimes grows in the same manner being confounded with it. This is the False Champignon (A. or Murutius ventricus), which is readily distinguished from the true Fairy-ring Mushroom by its having a flat top without any boss, and by its narrow gills being closely crowded together. The foregoing are the most commonly esteemed of edible British mushrooms. But there are a number of others which are not only wholesome but extremely delicate in flavour and nutritious. There is the Parasol Mushroom (A. prunence); the Maned Mushroom (Coprinus comatus), of which young specimens only should be used; the Red-fleshed Mushroom (A. rubescens); the Clouded Mushroom (A. nebularis), appearing late in autumn in moist places on the borders of woods; and the Orange-milk Mushroom (Lactarius or A: deliciosus). This last is much prized by connoisseurs in edible fungi on the Continent and in Britain. It has, as the name implies, orange-coloured milky sap in the head, and when broken or bruised both the flesh and the milk become green by exposure to the air. This is an excellent test when there is any doubt as to the identity of this and an allied but virulently poisonous species—L. tomentosum—in which both the flesh and the milk are white, and do not change colour when broken or bruised. Although many of the British fungi are wholesome and nutritious, yet it is proper that the inexperienced in diagnosing them should be cautioned strongly against eating any species of the wholesome qualities of which they are not absolutely assured. In many continental cities inspectors are appointed to examine all fungi that are brought to market, lest deleterious species should perchance be sold to the people. Those who desire to acquire an accurate knowledge of edible British species of fungi may refer to Dr Badman's Escential Funguses (1863), M. J. Berkeley's Outlines of British Fungology (1860), M. C. Cooke's Edible and Poisonous Fungi (1884), and other works cited at FN01. The culture of the common mushroom for profit in Britain has since 1875 become an important branch of gardening industry. About London in particular it is entered into by market-gardeners and even by specialists who live and thrive solely by the production of mushrooms for the million. To a lesser extent the industry is also
being taken up in the vicinity of the larger provincial towns. In Paris the catacombs are utilised for the growing of mushrooms, as are caves in all parts of France; and in Edinburgh the disused Scotland Street tunnel was acquired in 1886 for the same purpose. The principles of the culture of mushrooms are very simple, though considerable attention and skill are required in working out the practical details. For these, see W. Robinson's *Mushroom Culture* (1890).

**Music.** European music is by no means a spontaneous expression of ideas and sentiments, and it is only in a poetical sense that we can talk of the 'music' or 'melody' made, for example, by birds. Music is an art, and in order to make an impression on our minds it must take as its foundation the succession of sounds embodied in the scales we have chosen, and to which we are accustomed; it must also conform to the rules which have become the canon of music. We must look for its birth in Egypt, but it would serve no purpose here to occupy any space with the little that is known of Egyptian, or its offspring Greek music.

It is not improbable that the Israelites took with them to Palestine the music which they had learned in Egypt; and that many of the hymns of the early Christian church were identical with Temple melodies. As from these hymns was formulated the first authoritative musical system, we may say that in a double sense we are indebted to Egypt for the beginning of the science we were to see develop in Ambrose towards the close of the 4th century, and Gregory the Great two centuries afterwards, the indication of the measure 'two semibreves to the bar' (*Alta Breve*). In order to avoid a certain false relation of sound called the *tritonus*, which the pious old theorists called 'the very devil' ('Mi contra fa diabolus est in musica'), some of the church modes used B instead of A. This was also indicated by the 'B rotundum' (b) instead of the 'B quadratum' (b). These signs are the origin of our 'accidentals'—the flat (♭), which lowers the pitch of a note one semitone, and the natural (♮), which restores it. The sharp (♯), which raises the pitch, also a development of the 'B quadratum.' See also *Guido Ardentius*.

**Counterpoint** (1400-1600 A.D.).—Such were the materials with which Johannes Ockenheim or Okeghem (c. 1420—1513) and Josquin des Prés (c. 1450—1521) laid the foundation of Counterpoint (*punctus contra punctum*; 'note against note'), the art of combining one or more melodic parts with a principal melody called the 'Canto Fermo,' or fixed song. Counterpoint was the workshop in which were made many of the best tools used by great musicians of modern times. The art attained its perfection in the workshop of4 of Philippe de Vitry, in France, and at the end of the 16th century, just when a new departure by Monteverde became the inauguration of the new school of harmony which was to supersede the old contrapuntal school by assimilating all that was good therein. Other influences which helped to lay the foundation were the growing popularity and secularity of Madrigals (q.v.), at first distinguishable only by their words from church music; the improvement in organ-building and organ-playing, which encouraged freer part-writing and bolder melodic progressions than the limitations of supported imitative human voices allowed; and doubtless also the natural warmth of musical feeling which had found expression among the troubadours of France and the minnesingers of Germany, and in the rude popular songs of these early ages.

**Florence Academy.**—Most potent factor of all in this new birth of music was the invention (in 1584—1600) of recitative music and the introduction of the dramatic principle by the Florence Academy—a group of literati and artists who met in the house of Baldassare Capranica, a Florentine physician. Their aim and ambition was to restore the ancient accompanied Greek play; and by making use of all the slender resources which harmony could then put at their disposal they stumbled, as it were by accident, on the form of recitative, or, as they called it, 'Stilo rappresentativo.' The development of opera and oratorio, with all the various forms of aria, &c., was a natural consequent, a particular account of which will be found under their proper headings.

**Monteverde.**—The great landmark which separates the old school of counterpoint from the new is the compositions of Monteverde, whose importance is explained in the article on Harmony. It was only gradually that the new leap spread through the schools of Europe, and nearly one hundred years elapsed between the setting of Palestrina's *sola* and the birth of the two new morning-stars of modern music—Bach and Handel. The time, however, was well occupied. In vocal music greater freedom in the use of established forms was gradually attained, and new forms were invented, chief among which were the Aria *da capo* produced by Marenzio (1559—1729). He first used the 'second part,' which, followed by a *da capo* or repetition of the first strain, summarised for vocal music the tendency which was dominating all musical development.

The French Grand Opera school, founded by the Florentine Lully (1633—87), studied the art of
expressing in sound the most fleeting emotions to be found even in the ever-varying turns of thought in the mind.

Of still more importance was the progress made during the century in instrumental music. A great impetus to solo-playing in particular, and execution in general, was given by the improvement in the manufacture of violins. The centre of this interest was Venice, the home of the three famous families of Stradivarius, Guarnerius, and Amati, who worked for three generations. Some of their instruments are to-day literally worth more than their weight in gold.

Bach.—In 1685, on the 23rd of February and 15th of March respectively, were born Handel in Halle and Bach in Eisenach. From 1710 till 1722 Handel devoted all his energies and genius to writing operas after the Italian school, and most of his works have shared the fate of their contemporaries and rivals. He was then led into the paths of oratorio, and a brilliant succession of well-known compositions sheds an undying radiance on the last twenty years of his active life (see ORATORIO). Bach's influence has been wider and more far-reaching even than that of his great contemporary. Indeed, no less a critical authority than Brahms regards Bach as having been more and as much to Bach as Christianity does to its founder. By virtue of his complete and easy command of all the resources of harmony and counterpoint, his boundless originality and fertility, the invariably high level of his compositions, even when judged by his own high standard, he takes a place above all ancient and modern composers. Under his influence also the German school of composition chose the path of instrumental music, in which the voice is only one of a large orchestra of instruments, entitled to no more consideration than its limit demand. The attempt in Gluck's operas to reconcile the requirements of expressive instrumentation and the demands of the vocal school was more successful in theory than in reality (see GLUCK), and the true central column of progress has moved in German, in the instrumental lines in the hands of Bach, Mozart, Beethoven, Schumann, Wagner, and their contemporaries.

Sonata.—The most important form of instrumental music had hitherto been the Fugue (q.v.), and in its strict and heavy harness these giants of counterpoint were girded with the most ornate and dignified. But the age of monothematic work was about to pass away, and the old dance forms (allemande, courante, sarabande, gavotte, gigue) did not readily lend themselves to the requirements of thematic development, so necessary to instrumental music as a conception distinct from music, to which words at once give inspiration and impose limitation. Corelli, A. and D. Scarlatti, Bach, and others each strove to solve the problem in his own way, and the sum of their influences was handed from Emmanuel Bach to the 'foundator of the modern sonata,' Joseph Haydn.

The name 'sonata' was first used in Italy for music which was only to be played or 'sounded,' contrasted with 'esnata,' which was to be sung. The particular form, however, gradually separated itself from all other instrumental music, and when known, was only of the most simple kind. It was not until the middle of the 18th century that the sonata was much improved, so far as strict harmony was concerned, and is accepted, as the form par excellence. In its mould are concertos, symphonies, quartets, concertos, &c., and even the most romantic and during of fantasias find it necessary to recognise its claims. The principal characteristic of the sonatas are still very formal; also are Mozart's, though he had more in common with the Romantic school of the next century than with the older composer. This is shown by a comparison of their symphonies.

Haydn's are beautiful and graceful, but the themes and subjects he chooses are never very deep, nor can they claim the deep and added success of his airy and humorous quick movements. In Mozart's symphonies a nobler and more romantic spirit breathes—sometimes with most intense passion, sometimes with a dignified melancholy. And so the way was prepared for the most powerful and the most widely heralded of all the rulers in the realm of sound. In the works which are classed as his 'first period' Beethoven showed how he had studied and mastered the work of his great predecessors. In his second period he proceeded to build on the solid foundation that wonderful structure to which the vast conceptions of his third period form a fitting and glorious crown. Nothing important has been added to sonata form since Beethoven wrote the works between the Eroica and the Choral Symphonies (1803-23); and although much has since been written, much that is new, much that is original—although a ready appreciation is granted to the passion of Schumann, the romantic power of Schubert, the poetry of Chopin, the refined elegance of Mendelssohn, the successful use of new colour shown in later works by Brahms, Dvorak, Liszt, &c.—Beethoven's sonatas and symphonies still stand unrivalled, unchallenged.

Fantasia.—A desire for some more direct, more unfettered expression of feeling not unnaturally succeeded this long striving after adequate form. But, while all great composers devoted most of their genius to development, many composers, perhaps, did not; the growth of the fantasia was much neglected. Only when the greatest minds turned their attention for a moment from the more important aim of music was anything of lasting importance produced; and this became it only to the extreme to which the strict school of form to use all available resources which can wisely enjoy a liberty so easily converted into license. The earliest attempts in fantasia form were called 'toccatas' during the 17th century; and, notwithstanding excellent modern toccatas by Schumann, Rubbra, and others, we may say that the history of the toccata was brought to a close by the magnificent specimens written early in the 18th century by J. S. Bach. The same composer left a freer model than the somewhat formal toccata in one of the most famous and successful fantasia forms, and instrumental music has never attained nearer to the definiteness of articulate speech than in the great Chromatic Fantasia.

The strong romantic movement which naturally ensued after the perfection of the classical school in Beethoven's hands eagerly followed out the path he so often and with such effect indicated in his works; and, although the name fantasia has lately fallen into much disrepute by reason of many unworthy and worthless compositions, it may recover its fair fame when Schumann's and Schubert's fantasia forms have been surpassed. In any case the endless varieties of fantasia (i.e. unfettered) form, and their adoption in rhapsodies, symphonic poems, and the like, have proved as valuable and as potent a factor in modern romantic music as the various modifications that the sonata took. The independent form (e.g. Liszt's concertos and sonatas), Schumann adopted some very curious whimsical or poetical names for his smaller compositions—novelette, humoroske, carneval, &c.—and the idea has found great favour with many modern writers. The return to invention of the old fantasia forms is felt more identified with Chopin's dreamy genius. The latter composer also transfused the waltz and the polonaise and mazurka of his own unhappy country with such an intensity of passion, such a chivalrous
n nobility, and surrounded them with such a halo of
drama and romance that they are an important
addition to the resources of a modern composer,
and Chopin's name overshadows that of Schubert
and Weber, each of whom is in the same field
"Deutsche Tinten, L'lnitation à la Valse).
The latest developments in instrumental music are
intense nationality in colour and thought, as shown in
the works of Grieg, Dvorak, Liszt, MacKenzie, and
a new striving after more definiteness which was
unnoticed by Beethoven in the same field.

Vocal Music.—The progress of vocal music from
its first great triumph in 16th-century counterpart
was much slower and varied than that of instru-
mental. The reason of this is not hard to find;
for the conception of vocal writing in the contrap-
untal school was sound and artistic, and it reached
a point of absolute perfection in that epoch called
the 'Golden Age.' Thus there was not the neces-
sity for that advance which over improving instru-
ments and the feeling for instrumental effects
demanded. Indeed, in choral music exactly the same
principles furnished the reverse of counterpart in the 16th century, must be recog-
nized by composers of to-day who wish to produce
the purest and grandest effects; and the rules

MUSIC

MUSICAL BOX

sight of the multitude [Barabba's] and the complex chorus 'Let Him come down from the cross,' show that a genius in no way inferior to Wagner's, but with comparatively very limited resources, could grapple with the same problem which is so marvellously solved in the street riot scene of Ring. His instrument's feeling to see the difficulty, but his powers were not great enough to overcome it. Mozart's greater, and in this matter somewhat irresponsible, genius never troubled itself on the subject.

**Orchestra.—** It only remains to describe shortly the individual instruments and the groupings which have clung to and an account of the latest development in European music. Monteverde laid the foundation of the modern orchestra when he multiplied the stringed instruments and relegated the pianoforte (or rather its precursor the harpsichord) to a somewhat subordinate position. The latter, however, maintained its place in the orchestra till after Handel's day. Between Monteverde and Haydn many experiments were made in the arrangement and combinations of instruments; also in the manufacture of the instruments themselves. By-and-by (the time of Mozart, di Braccia, &c.) resolved themselves into the viola or tenor violin, and the violoncello (i.e. 'the little violon' or smaller double bass). The violin is of course the little viol. And these remain the foundation of our orchestra. The wind instruments were used for the chorus (a compromise among various forms—Obi d'Amore, di Caccia, &c.), to which the bassoon gave the bass. To these were added trumpets and drums for special effects. Such was the orchestra with which Haydn laid the cornerstone of modern instrumentation. Mozart added the clarinet, in clarinet, was used in the incorporated in the band. The piccolo, or little flute, and the double bassoon (Contra Fagotto) can hardly be called additions in the sense of novelty; and from Mozart's time to Wagner's the improvement, with one important exception, has been in the direction of improvement in mechanism, and in power of variety in combinations and tone colours. The exception is the trumpet, first used with its full effect by Mozart in Don Giovanni, and ever becoming more important in the hands of Beethoven, Schubert, Schumann, and Wagner. Berlioz, the great director of instrumentation in the modern world has seen, embodied the result of his experience in a 'Treatise' which will ever remain one of the greatest monuments of his extraordinary genius. He has been wonderfully followed by the scarcely less successful Wagner, and an enumeration of the instruments at his masterly disposal will show what limitless combinations and permutations are now possible. In Tannhäuser, the orchestra for which he writes comprises, besides the usual stringed band (about 12 first violins, 12 second violins, 8 violas, 6 violoncellos, and 6 double basses), 3 flutes, 1 piccolo, 2 oboes, 2 clarinets, 1 bass clarinet, 2 bassoons, 2 horns, 2 valve horns, 3 trumpets, 3 trombones, and 1 bass tuba, with a pair of kettle-drums, bass drum, cymbals, triangle, tambourine, and harp; and, on the stage, 4 small piccolos, 4 oboes, 6 cornets, 6 clarinets, 6 bassoons, 12 trumpets, 12 horns, 4 trombones, cymbals, triangle, and tambourine.

**Programme Music.**—Many attempts of a more or less legitimate kind have been made to illustrate by abstract music a certain story, set of ideas, or progress of emotions. Probably the earliest examples which can be pronounced artistically successful are the famous Pastoral Symphony and the sonata Les Adieux, L'Absence, et le Retour, by Beethoven. To criticise this tendency would lead us far beyond the limits of this article, and a mere enumeration of names and compositions will suffice to show what an attraction the idea has had for almost all modern composers. Mendelssohn has tried to paint Fingal's Cave in his Hebrides overture, and in his Scotch Symphony he seeks to convey the impressions made on him during his visit to Scotland. Schumann has painted a whole series of figures and characters in his Cora, and in his great Fantasia C he has set out with a very definite intention to convey the meaning of a verse by the poet Schlegel. Berlioz has gone further and proposed to tell the Episode in the Life of an Artist in a symphony. Unfortunately too many of our modern composers, whose genius has chosen very repulsive pictures for his themes; and he also makes the mistake of entrusting a certain character or sentiment to a certain phrase—evidently impossible without words set to the music or a previous explanation. Raff's Le Noire Symphony, MacKenzie's Le Belle Dame, and Liszt's Mazeppa are good examples of well-known poems set forth in music alone. MacCunn's Land of the Mountain and the Flood is a descriptive overture; and Liszt's and Saint-Saëns' Symphonic Poems are very beautiful and expressive.

Of course, descriptive music which occurs in the course of a cantata (e.g. in David's Le Desert or Berlioz's Faust) has the advantage of a definite starting-point in the words which surround and explain it, and therefore is distinct from these works mentioned which aim at dispensing with words except as an aid to heighten the emotional effect. The composer has attended the attempts is certainly unequal, but an immense new field of effort has been opened to composers which will doubtless yield a rich harvest.

Whither music is tending in the 19th century it is difficult to say; but so long as the treasures left us by the great composers are as reverently and as earnestly studied and accepted as they are at present; so long as composers recognise that their genius is a call to labour and not to enjoyment; so long as criticism is honest and based upon sound knowledge, there is no fear that the heritage on the ages will be lost. It is noteworthy that in almost every country in Europe a keenly national spirit is alive, which lovingly studies all available treasures of national music and melody, appreciating it with an insight and breadth only to be obtained in a school of wide and deep musical culture. See the general histories of music by Lenox (2 vols. 1882-86), Ritter (1880), Rockstro (1886), Rowbotham (1886), Ambros (Leip. 23 ed. 1881), Félix (Paris, 5 vols. 1868-76), F. Weber (1882), Parry (1894); Davy, History of English Music (1883); Marx, Music of the 19th Century (21 ed. 1879); Hollàh, Modern Music (1861; new ed. 1875); Rieman's Dictionary of Music (trans. 1896); and Grove's Dictionary of Music and Musicians (4 vols. 1877-89). **Musical Box.** A case containing a mechanism which, when the spring is wound up, plays tunes automatically. Teeth projecting from a barrel (as in a barrel-organ or a mechanical peal of chimes) impinge on and set vibrating the tongues cut out
MUSK-RAT

in comb or steel plate; the difference of tone being due to the greater length and breadth of the teeth. The larger and better boxes, some of which play many tunes after one winding up, can be regulated in pace by a fly regulator, with flat wings, which catch the air. The invention dates from about the middle of the 18th century. Switzerland (especially Aargau) is the headquar- ters of the manufacture.

Musical Glasses. See HARMONICA.

Musk. The musk of commerce, which is an important element in very many compounded perfumes, is mainly obtained from the Musk-deer (q.v.), the best kind being that known as Chinese musk, and imported from Tonquin. Other kinds are Indian (from the Himalayas and the Siberian. Musk is often adulterated with dried blood, bits of leather, &c. In 1890 Baner of Erfort produced an artificial musk by treating butyl-toluol with a mixture of sulphuric and nitric acids, the resulting nitro-compound being purified by crystallisation from alcohol.

Musk-deer (Moschus moschiferus) is a ramifying Ungulate forming a special family of the Artiodactyla. According to Flower, it represents an ancestral type of the Peers (Bovidae, Cervidae, Giraffidae), but with nearest affinities to the Deer (Cervidae). As in the Cervidae, the young is spotted, but it has no horns, and the canine teeth of the male project in the form of longish tusks; this latter fact has led to the association of Moschus with the Tragulidae (Chevrotains, q.v.), which is, however, not justified by its other characters. The musk-deer is an inhabitant of the mountainous regions of central Asia from the extreme north to as far south as Cochin-China and Nepal. There is only one species, with perhaps four well-marked varieties. The musk-deer is much hunted on account of the odoriferous secretion which is found in a special gland upon the hinder-part of the abdomen of the male. This substance was first introduced into the west by the Arabs. It is spoken of in the pharmacologies of Serapion and Avicenna and by the traveller Marco Polo. The value of the substance used to be very great, as it figures among the costly objects presented by Saladin to the Greek emperor in 1189. It was used in the embalming of bodies as early as the 14th century. For an interesting account of the musk-deer (and the Chevrotains), see Milne-Edwards, Annales des Sciences Naturelles (1884); and for the anatomy, Flower, Proc. Zool. Soc. 1875.

Muskegon, capital of Muskegon county, Michigan, is on the Muskegon River, which here (4 miles from its mouth in Lake Michigan) widens into Muskegon Lake, the best harbour on the east side of Lake Michigan. Muskegon is 40 miles by rail NW. of Chicago, and is the terminus of a steamboat communication with Chicago, and saws and ships enormous quantities of lumber. It has also a number of foundries, machine-shops, boiler-works, &c. Pop. (1900) 29,818.

Musket. See Firearms.

Muskskins, skin-pits in mammals producing a very agreeable smell. They belong to a series of skin-glands, which occur in various parts of the body and with various secretions (see Anal Glands). The most notable musk-glands are those of the male musk-deer and the male beaver. See BEAVER, CASTOREUM, CIVET, &c.

Musk or Muscovy Duck. See DUCK.

Musk-ox (Ovibos moschatus) is a member of the family Bovidae. It inhabits at present the most northern parts of the American continent north of lat. 60°. Its remains, which have been found in Quaternary deposits of England, Europe, and Siberia, indicate that it had formerly a much wider range. The hair is long, serving of course to protect the animal from the rigour of the climate which prevails in its habitat, and of a brownish colour. The creature measures about 5 feet from the tip of the nose to the root of the tail, and so appears in size to be a small Highland cattle. It is gregarious, there being only one or two males to a herd of eighty or a hundred. They browse on grass, reinder moss, willow shoots, the Labrador tea-plant, and crowberry bushes. The flesh of the calves and caws, when in condition, is very palatable. Unlike many purely Arctic animals—e.g. the Arctic fox—the hair does not become white at the approach of winter. But it has been suggested that this protective change in coloration is not necessarily connected, and which lives in herds; hence it is better for an individual, which has got accidentally separated from its fellows, to regain a position of safety by being able to readily detect the whereabouts of the herd than to trust to escape from carnivorous foes by a resemblance in colour to the surrounding snow.

Musk-plants. Various parts of a number of plants smell more or less strongly of musk. Among these are the common little Musk-plant (see Mimulus) and the Musk-seed (see Hibiscus). The musk-tree of Jamaica (Muscovryum Swartzii), belonging to the natural order Malianceae, emits from all parts a smell of musk. All parts of Guarea grandifolia, another tree of the same order, a native of the West Indies, sometimes called muskwood, also smells strongly of musk. The drug called Musk-root or Sambuli is the root of a plant of the natural order Umbelliferae, and is brought from Persia or central Asia; it has a pure musky odour, and is used as a substitute for musk.

Musk-rat, a name applied to several distinct animals. (1) The Pesman (Myogale), a genus of insectivorous quadrupeds of the Shrew (q.v.) family (Soricidae), differing from the true Shrews (Soræ) in having two very small teeth between the two large incisors of the lower jaw, and the upper incisors flattened and triangular. Behind these incisors are six or seven small teeth (lateral incisors or false canine teeth) and four jagged molars. The muzzle is elongated into a small flexible proboscis, which is constantly in motion. The eyes are very small; there are no external ears; the fur is long, straight, and divergent; the tail long, scaly, and flattened at the sides. All the feet have five toes, fully webbed; and the animals are entirely aquatic, inhabiting lakes and rivers, and making holes in the banks with the entrance from beneath the surface of the water. Only two species are known: one (M. pygmaea), about 8 inches long, with tail as long as the body, a native of the streams of the
Pyrenees; another larger species (M. moschata), very plentiful in the Volga and other rivers and lakes of the south of Russia, nearly equal in size to the common hedgehog, with tail about three-fourths of the length of the body. The Russian desman is blackish above, whitish beneath; it has long silky fur, with a slight, almost imperceptible glitter, and the fur is held in some esteem. Desman skins, however, are chiefly valued on account of the musky odour which they long exhaled, and which is derived from a fatty secretion produced by small follicles under the tail of the animal. The desman feeds on leeches, aquatic larvae, &c., searching for them in the mud by means of its flexible prehensile. It seldom, if ever, voluntarily leaves the water, except in the interior of its burrows, which are sometimes 20 feet long. (2) The name of Musk-rat is also a common name for an Indian species of Shrew (Sorex macrurus), in size about equal to the common brown rat, in form and colour much resembling the common shrew of Britain, but remarkable for the powerful musky odour of a secretion which proceeds from glands on its belly and flanks. (3) The name is also given to the Musquash (q.v.).

**Muslin**, a fine cotton fabric somewhat resembling Gauze (q.v.) in appearance, but it is woven plain without any looping of the warp threads on the weft. A piece of the finest muslin at one time manufactured at Dacca in India, measuring 3 yards in length by 1 in breadth, weighed only the fifth part of an ounce, and cost £40; but none approaching to this in fineness is made in India now. Very fine muslin has been woven from yarn spun by machinery at Manchester, but it wanted the delicate softness of the finest Dacca. Printed muslins are made in France and England for female summer attire. In India some muslins are woven with coloured patterns; others are embroidered with silk or beetles' wings; others again are printed with gold and silver leaf. Such names as 'woven air' and 'evening dew' are given in that country to those of exquisitely fine texture.

**Musquash**, also called Musk-rat, or Ondatra (Fiber zibethicus), a rodent quadruped, a native of North America, from the Rio Grande to the Arctic regions. The genus to which it belongs contains only one other species, F. alleni, from Florida. They belong to the family Muridae. The musquash is in shape nearly similar to the brown rat; the head and body are about 15 inches in length, the tail 10 inches. The whole body is covered with a short, downy, dark-brown fur, intermixed with longer and coarser hairs. It is a very aquatic animal, seldom wandering from the rivers, lakes, or marshes in which it makes its abode. It is chiefly a vegetable feeder, but like other Muridae will occasionally take animal food—the moulusc Unio is a favourite delicacy. The fur is in demand, and forms an article of commerce—skins in large numbers being still exported from America to Britain and other European countries. The musquash burrows in the banks of streams and ponds, the entrances of its burrows being always under water. In marshes the musquash builds a kind of hut, collecting coarse grasses and mud, and raising the fabric from 2 to 4 feet above the water. The flesh of the musquash, at those seasons when it is fat, is in some request among the American Indians, and is said to be not unpalatable.

**Mussel**, a name applied to several common bivalves or Lamellibranch molluses. (1) The Common Sea-mussel (Mytilus edulis), very important for bait and not infrequently used as food, is widely distributed in crowded 'beds' between high and low water marks. It is usually sedentary and firmly anchored by yellowish silken 'byssus,' but it is also able to shift its quarters and even to climb by slowly extending the range of the byssal thread exuded from the 'foot.' (2) The Horse-mussel (Modiolus modiolus) is nearly twice as large as the above, and lives a more active burrowing life below the low-water mark. It is never used for food, and is not available for bait. Both these sea-mussels are representative of large genera, and are included in one family—Mytilidae. (3) Quite different from the above are the fresh-water mussels, Unioidei, widely distributed in lakes and rivers, where they plough their way slowly along the bottom from one resting-place to another. As good representatives of the Unioidei, the Pond-mussel, Anodonta cygnea, the Painter's Mussel, Unionia pictorum, whose shells were once used for holding water-colour paints, and the Pearl-mussel, Margaritana margaritifera (see Pearl), may be noted. For the structure and general characters, see BIVALVES.

The common edible mussel abounds on the Atlantic seaboard of the United States, but is used neither as food nor as bait. In England it is largely used as human food; in Scotland it is not so used, but enormous quantities are required for bait, especially by haddock fishers. The chief objection to mussels as food is that they are occasionally poisonous. Mussels especially which are unheathy or dead are very apt to contain dangerously poisonous waste-products; care should accordingly be taken that those used for food are thoroughly fresh. A French Commission reported in 1889 that the poison is due to the presence in the mussel of a volatile alkaloid developed under the influence of a particular microbe, which is only found in mussels growing in stagnant and polluted water. Sewage fairly free from the pollution of manufactories is distinctly

beneficial to mussel culture. It is said on good authority that mussels lose any poisonous properties they may have if cooked for ten minutes with carbonate of soda. The wasteful and unregulated consumption of mussels from the scalps on the British coasts, the reckless destruction of immature mussels, and the wholly inadequate efforts to check the wasteful force of the fishery, have caused an immense anxiety over some parts of Britain a mussel famine, and necessitated large importations from abroad. Great natural scalps on the British coasts are those of the Wash, Morecambe Bay, and the estuary of the Clyde. The last, from which it is computed that the catch is not of 200,000 tons is now exhausted and unproductive. The cultivation is practised in the Thames estuary and the Medway, in the Teign and Exe, at Montrose, and elsewhere; but large supplies are imported from Holland. Scotland imports from England, the north of Ireland, and Hamburg. In one year the Ecmouth fishermen have used nine hundred and twenty tons of mussels, mainly imported, and costing £1,000. Yet in Lancashire and Norfolk mussels are wastefully used as mutton in stews, and therewith either on natural beds—especially where clean gravelly bottoms are exposed to low water, and where salt and fresh water mix—by transplanting spat and protecting young mussels; or in deep water, where transplantation may also be practised. In north Germany, mussels are cultivated on wicker-work attached to pilacles. The Dutch artificial beds are mainly provided with spat from the coasts of Essex and Kent.

Musselburgh, an old-fashioned town of Midlothian, near the mouth of the Esk in the Firth of Forth, 5 miles E. of Edinburgh by a branch-line (1847). Since 1832 it has united with Leith and Portobello, which formerly belonged to Musselburgh including the large fishing-suburb of Fisherrow, with a small tidal harbour, and the pretty village of Inveresk, whose conspicuous spired church was rebuilt in 1895 by 'Jupiter' Carlyle, and occupies a Roman praetorium. Musselburgh's chief features are its celebrated golf links (since 1817 also the Edinburgh racecourses), Loretto school (marking the site of a famed place of pilgrimage), Pinkie House (1613), the 'Roman bridge, the quaint tolbooth, and a statue of David Hume. The sea front is made by various nautical leather, &c. Pop. (1841) 6366; (1881) 7566; (1891) 8888. See Paterson's History of Musselburgh (1857).

Muset, Alfred de, one of the most striking figures in the literature of modern France, was born in Paris, 11th December 1810, the son of an official who rose high in the War Office. He was unusually impulsive from his childhood, and precocious in sensibility and in genius, and grew up handsome in person and fascinating in manners, though he retained something of the spoilt child all his life. He thought first of law, next of medicine, then of art, but at eighteen discovered himself to be a poet, and scarcely a year after published his Contes d'Espagne et d'Italie, a collection of unequal poems, which secured him a literary reputation, and to which at least are still remembered. A splendid and brilliant youth, of equal grace and assurance, he was warmly received into Victor Hugo's Océane, the inner circle of militant Romanticism; was crowned with all the flatteries by the wider world of society; and in his twentyninth year for public experience at once thung himself recklessly into the eager pursuit of pleasure in every form. He was eager to feel, and feeling brought suffering in his train, but gave him the impulse out of which came his verse—ever a part of himself, the answering echo of his own emotions. His piece La Nuit Vénitienne failed at the Odéon in 1830, and thus turned him from a career in which he was yet to gain triumphs without seeking for them. In 1832 he published Un Spectacle dans un Fourreau, comprising two short plays—La Coupe et les Lèvres and À quoi récent les Jeunes Filles, as well as the poem of Nommons, written hastily to eke out a slender voice of applause. The next year appeared the Revue des Deux Mondes two of his very greatest works, the tragic comedies André del Sarto and Les Caprices de Marianne. It was of Marianne that her creator replied, when asked where he had found her character, 'Nowhere and Nowhere.' Next followed the famous poem of Roland, which has not sustained the applause with which it was received. Then came the fatal journey to Italy with George Sand. He first met her in the summer of 1833, and the intimacy quickly blossomed into love. The projected tour was at first opposed by De Musset's mother, but George Sand took the extraordinary step of calling upon her one evening, and in a moment of emotion gained her consent. They set out for Venice at the beginning of winter. About this time his friend Baudelaire and his mistress, Delphine, with whom he was then in intoxication and brother ceased; for six weeks there was silence, then on the 10th April he reappeared alone, broken, in health and sunk in the deepest depression of spirits. A quarter of a century later, and soon after his death, she gave the world, in the guise of a novel, the account of a series of incidents which led to the catastrophe. Paul de Musset at once retorted with Lui et Elle (1859), a book poor as fiction, but which rings like truth. His account was that she had been grossly unfaithful to him, and that his discovery of this in a state of weak health had thrown him on an abject brain-fever; she, on the other hand, explained the infidelity as but a delusion of the fever itself. It is at any rate unsuspicious that but one of the pair suffered deeply, while the other went on calmly writing romances, and utilising the experience at once as impulsive and material. The Jacques Laurent of her story bears many a trait of the true De Musset. Despite or, more probably, in consequence of his sufferings, the five years that followed his return were his best years of production.

Another book followed—his departure was unhappy; and that again was succeeded by a series of unworthy and often sordid entanglements, which distracted his heart and were followed by periods of deep depression which alcohol did little to allay. The patronage of the Duc d'Orléans, the warmth of his friends, and his appointment in 1838 to be librarian at the Home Office did something to take him out of himself, but he was ever a capricious in character as in genius, and the feverish activity that sometimes seized him sooon exhausted itself in splendid projects and unfulfilled hopes. Even his famous Confession d'un Enfant de Série (1835), like most of his works, was begun, laid aside, and then finished under a cloud of sorrow. It is not an autobiography, though it owes its sombre colour to its author's personal experience. It is a striking study of man's vanity, hate and weariness, an expression of cynical contempt for the world and of the misery of hopeless doubt; but, as a work of art, it breaks down pitifully at the close into weakness and platitude. When De Musset's health gave way about 1840 his literary career began to decline also. He was already, in Helène's phrase, 'a young man who had a splendid past;' he felt himself an old man at thirty, and to the end he was never blessed with anything of the serenity of the Olympians, nor was he even one of those artists who find consolation in their art. The success of Un Caprice at the Théâtre Français in 1847 recalled
hun for some time to life and hope, but during his last half-dozen years he wrote nothing of importance. He was elected to the Académy, but not without difficulty, in 1852, and Sainte-Beuve then said to Maubuée: "'N'aie pas peur de la répétition, s'absente trop,' said a member on one occasion; 'il s'absente trop,' was the response. He died of heart disease, May 1, 1857.

Of De Musset's poetry the four pieces entitled Nuits mark the highest reach of his lyrical talent. The Nuit de Mars, that 'October is pure and immortal poems, like Milton's H. Penefrioso with passion added, says Sainte-Beuve. The Nuit de Décembre is a subtle realisation of that other self that had shadowed all his life. These poems quiver with the quick pulse of life and the throng of suffering, yet the poet's eyes are open throughout to all the innumerable beauties of the universe. The Ode à la Mélodie is a splendid tribute of admiration to a great actress; the Lettre à Lamartine, to a master in his own art; L'Esprit en Rien, a noble expression of the longing of the human soul for certainty; the famous Rhin Allemand, a spiritual retort to Nikolaus Becker's too patriotic German poem, which brought him a crop of challenges from foolish German officers. The greatest merit of these poems is that they thrill with real, not simulated, passion, and are verse. "Non dans mon verre" was his own judgment of himself, and so far as regards his genuineness it is true. He is the poet of a certain range of personal emotions, of youthfulness, and, above all, of passion, in which respect he follows close upon Byron in power, while far surpassing him in unaffectedness and reality, if not always in finish and exquisiteness of art.

His dramatic work is unique in 19th-century literature of its kind for originality, intensity, and variety, linked to brilliant wit and real dramatic genius. It consisted of comédies, or regular dramas, full of tragic quality and ending with tragic abruptness, and proverbes, the latter short dramatic illustrations of some common saying. Of the former class are André du Sart, perhaps his greatest work; Lorenzaccio; Les Caprices de Madame de S.; Le Chandelier, or the Amoureuse. To the class of proverbes belong Fantasie and Barberine, both bright and graceful, if fantastic; Le Chandelier, slight in structure, but absolutely perfect in art; Il ne faut jurer de Rien, more serious, but no less successful; Les Caprices, graceful, finish, with; Il y a une Partie de cards ouverle ou fermée, bright and charming; Louison, in verse, less interesting; On se saurait penser à tout, an extravagance; Carnavals, a charming little masterpiece of romance in miniature; and Bétone, a lively little drama.

Of his longest although not greatest prose work we have already spoken. It remains only to speak of his brilliant and inimitable Nouvelles or short stories and his Contes. To the former belong Les Deux Mautifuls, in which Valentin is said to have based his novel, and others like him; En Save; Le Fil du Tigre, perhaps his finest work in prose; Frédéric et Bernette, which grew out of an unworthy liaison of his own; Croissades; and Margot. The Contes are Pierre et Camille; Mademoiselle Mimi Pasin, a charming study of the best aspect of the feminine of modern Paris; and a work of art an absolute masterpiece; Le Secret de Javotte; Le Merle Blanc; and Lettres de Dupuis et Cotonet. His Mélanges and Œuvres Posthumes are less valuable. De Musset's whole work fills but ten small volumes (Lemercier, 1876), but it is not too much to say that these include some of the noblest poetry, greatest plays, and best short stories French literature has yet produced.
it is usual to mix the two, so as to fully develop the action of the latter. The use of boiling water is of course inadmissible in forming such a poultice, as it rots the flesh; the vinegar, or the vinegar-dressing, on the virtues partly depend (see Blisters). "Mustard papers," used as vesicants, are made of mustard flour deprived of its fixed oil. The cake that remains after the oil is extracted must be given to cattle as a condiment. The Mustard-tree of Scripture has been supposed to be Satureja perrisera, a small tree of the natural order Salvadoraceae; but other interpreters insist that the ordinary black mustard is meant in the proverb.

**Mustelidae**, a family in the bear section of the Carnivora, or, when not artificially divided into otter-like (Lutrini), badger-like (Molinae), and weasel-like (Musteline) sub-families. See the articles on these and related types.

**Musulman** (Persian form of Arabic Muslim), a Moslem or Mohammedan. We need hardly add that the termination 'fan' has nothing to do with our word men, and that a further English plural Muslimes, instead of Muslumans, is both barbarous and absurd.

**Muta Nzige**, a lake of Equatorial Africa discovered by Stanley in 1876, and again seen by him in 1889, and renamed the Albert Edward Nyanza. It occupies the southern end of a vast natural depression, of which the Albert Nyanza (q.v.) fills the southern extensity.

**Mute**, a small instrument used to modify the sound of the violin or violincello. It is made of hard wood, ivory, or brass, and is attached to the bridge by means of a slit, its three legs standing between, but clear of, the strings. The use of the mute both softens the tone and imparts to it a peculiar muffled and tremulous quality, which is sometimes very effective. Its employment is indicated by the letters c.s., or con sordino, and its discontinuance by s.s., or senza sordino. A mute, consisting of a pear-shaped leather pad, is sometimes used for the horn and trumpet. It is inserted into the bell of the instrument, thereby softening the sound and producing the effect of a sordino.

**Mutiny**, as defined by British military law, is 'collective insubordination,' or the combination of two or more persons to resist or induce others to resist lawful military authority. The punishment laid down in the Army Act of 1881 for this crime under failing when present to use the utmost effort to suppress, or when knowing of an actual or intended mutiny, failing to give notice of it to the commanding officer, is death or such lesser punishment as a court-martial shall award. It may be pointed out that, in view of the above legal definition, one man alone cannot be guilty of mutiny, but may be charged with 'insubordination,' a crime which, in its worst forms, is also punishable by death. On board ship the mutiny of the Bounty (see Pitcairn Island) in 1789 is memorable, and of that on board the Demid frigate in 1800; the greatest naval mutiny at the Nore (q.v.) in 1797 is dealt with specially. The Indian Mutiny is a common name of the Sepoy rebellion of 1857. See India.

**Mutiny Act** was an act passed by the British parliament from year to year, to regulate the government of the army. The navy and marines, when not in commission, are under Naval Discipline Acts, 1861 and 1879. The successors of Articles of War first enacted under Charles II., which, unlike the Mutiny Act, remained in force for an indefinite time. By the Bill of Rights the maintenance of a standing army in time of peace, unless by consent of parliament, was declared illegal, and from that time the number of troops to be maintained, and the cost of the different branches of the service, have been regulated by an annual vote of the House of Commons. In time of war or rebellion, were always subject to military law; but the occurrence of a mutiny in certain Scottish regiments soon after the Revolution raised the question whether the same law could be enforced in time of peace; and it was decided that, in the absence of any statute to the contrary, a soldier in time of peace was only amenable to the common law: if he deserted, he was only liable for breach of contract; or if he struck his officer, to an indictment for assault. The authority of the legislature became indispensable to the maintenance of discipline, and parliament, from 1689 till 1879, conferred this and other powers in the Mutiny Act, limited in its duration at one time to six months, but latterly to a year. Although it was greatly changed from the form in which it first passed, the annual alterations of the code, at first, and, later, a fixed form. The preamble quoting the above declaration from the Bill of Rights added that it was judged necessary that a force of specified strength should be continued, while it gave authority to the sovereign to enact Articles of War for the government of the Army. The act specified the persons liable to its provisions, treated of courts-martial crimes and punishments, and of military prisons, furlough, Enlistment (q.v.), stoppages, billets, and the conveyance and entertainment of troops. For years prior to 1875 attention had been drawn in parliament and elsewhere to the shortcomings of the act, as well as to those of the Articles of War (q.v.) by which it was accompanied, explained, and amplified. These representations culminated in the appointment of a parliamentary committee which in 1881 made a Bill to supersede the Mutiny Act, and, like it, to be passed annually as the 'Army Discipline and Regulation Act.' The Marine Forces when serving on shore were under the Marine Mutiny Act up to 1879; then they were brought under the 'Army Discipline and Regulation Act.' In 1881 this was slightly modified and called the 'Army Act of 1881.' It is brought into force annually by a short act called the Army Annual Act, which lays down the number of troops to be kept up for the ensuing twelve months, the prices to be paid in billets, and the conditions of enlistment in the Army Act itself. The latter is accompanied by Rules of Procedure for its administration, and contains the whole military law of Great Britain.

**Muttra**, or MATHURA, a town of India, in the North-west Provinces, is situated on the right bank of the Jumna, 50 miles above Agra. For centuries it was a centre of the Buddhist faith, and the surrounding country teems with traditions of Krishna (or Vishnu, q.v.) and his brother Balarama. There are numerous temples and mosques; the river is lined with magnificent flights of stairs, leading down to the bathing-places in the sacred river; large numbers of pilgrims resort to the city on the occasion of its religious festivals; and troops of monkeys and turtles are supported by the charity of the gentle-hearted people. The city has passed through a long series of misfortunes; it was sacked by Mahan Shah of Oraon in 1651, and the great temple was destroyed by a native sultan in 1560, and by Aurungzebe in 1669; and it was plundered by the Afghans in 1746. In 1803 it passed into the hands of the British. Pop. (1881) 57,724; (1891) 61,185.

—The district contains an area of 1,332 sq. m., and a pop. (1881) of 671,696; (1891) 772,974.

**Myscas.** See Colombia.
Muzaffarnagar, a municipality in the North-Western Provinces of India and capital of a district (area, 1656 sq. m.; pop. in 1891, 772,574), 80 miles N.E. of Delhi by rail. Pop. 15,080.

Muzaffarpur, a capital of a district (area, 3093 sq. m.; pop. in 1891, 2,711,445) in Bengal, on the Little Gandak, 140 miles N. by rail of the Ganges and Doab. Pop. 20,000.

Myall Wood, the hard violet-scented wood of the Australian Acacia homophylla, much used for making whip-handles and tobacco-pipes.

Mycale, a woody promontory of ancient Ionia, over against Samos; in the channel between them, Leuctridhes the Spartan and Xanthippus the Athenian defeated the Persian fleet, 479 B.C.

Mycelium, the vegetative part of fungi which is not concerned in spore-bearing. It may consist simply of a much-elongated cell growing from the spore, or of a chain of cells, but in the majority it is a tissue of interlaced branched filaments or hyphae, loosely united in many moulds, membranous in dry-rot, compact and tuberous in mushrooms. See FUNGUS.

Myce'lia, a very ancient city in the north-eastern part of Argolis, in the Peloponnese, built upon a craggy height, and said to have been founded by Perseus. It was the capital of Aegamemon's kingdom, and was at that time the principal city in Greece. About 465 B.C. it was destroyed by the inhabitants of Argos, and never rose again to anything like its former prosperity. In Strabo's time its ruins alone remained; these are still to be seen in the neighbourhood of Kharravi, and are noble specimens of Cyclopean architectural work. The most celebrated are the 'Gate of Lions,' chief entrance to the ancient Acropolis, and the 'Treasury of Atene.' Excavations prosecuted at Mycenae by Dr Henry Schlie mann brought to light in 1876 another subterranean treasury and several ancient tombs, containing, with architectural fragments, terracotta vases, weapons, gold death-masks (see MASKS), and other ornaments of thin hammered gold. Good authorities say these objects show a type of art derived from Mesopotamia through Phoenicia and Asia Minor, with little or no trace of Greek tastes, beliefs, or usages. Their date seems to be about that of B.C. 1500 (see GREECE, Vol. V. p. 380). See Schliemann's Mycenae and Tiryns (trans. 1877) and The Mycenaean Age (1897) by Tsountas, Marrett, and others.

Myctozoa. See MYXOMYCETES.

Myellitis (myelos, 'marrow') is the term employed to signify inflammation of the substance of the spinal cord. It may be either acute or chronic, but the latter is by far the most common affection. The chronic form begins with a little uneasiness in the spine, somewhat disordered sensations in the extremities, and unusual fatigue after any slight exertion. After a short time paralytic symptoms appear, and slowly increase. The gait becomes uncertain and tottering, and at length the limbs fail to support the body. The paralysis finally attacks the bladder and rectum, and the evacuations are discharges involuntarily; and death takes place as the result of exhaustion, or occasionally of asphyxia if the paralysis involves the chest. In the acute form the symptoms are those of the chronic form, but they occur more rapidly and with greater severity, and death sometimes takes place in a few days. Pain may be present in the spine, or in the parts of the body whose nerves pass over the diseased area of the spinal cord; but it is not usually a prominent symptom when the morbid process begins in the cord itself.

The most common causes of this disease are falls, blows, and strains from over-exertion; but sexual abuses and intemperate habits occasionally induce it. It may also result from other diseases of the spine (as epleies), or may be propagated from inflammation of the corresponding spinal parts.

The treatment, which is much the same as that of inflammation elsewhere, must be confided entirely to the medical practitioner; and it is therefore unnecessary to enter into any details regarding its application. There has, however, been little hope for, but in the early stage the disease is often checked by judicious remedies.

Mygale. See BIRD-CATCHING SPIDER.

Myilitta, a Babylonian goddess of fruitfulness, procreation, and birth, in whose honour, according to Herodotus, every girl had once in her life to give herself up to the embraces of a stranger.

Mylodon (Gr. 'grinder-teeth'), a genus of huge fossil sloths, whose remains are found in the Pleistocene deposits of America, associated with the Megatherium and other allied genera. A complete skeleton of the best-known species (M. robustus), dug up at Buenos Ayres, measured 11 feet from the forpart of the skull to the end of the tail. Another species from the same region was considerably larger, and was found rambling about with the remains of one species (M. Harlani) having been found in Kentucky. Although like the modern sloth in general structure and dentition, the immense size of Mylodon forbids us to suppose that it could have had the same arboreal habits, and the modifications of its structure seem to have fitted it for the uprooting and prorattng of the trees, the foliage of which supplied it with food.

Myna (Acrithotheres, or Gracula of Cuvier), a genus of birds of the family Sturnidae, of which there are seven species ranging over the whole oriental region and Celebes. The head is more or less crested, and some have a naked space behind and under the eye; the bill is rather short, stout, and compressed; the tail is rounded; the feet are strong, the toes long, and the claws moderately enveloped. The Common Myna (A. tristis), which is found in the east coasts of Anna and Burma, measures about 10 inches in length, and is of a glossy black colour on the head, neck, and breast; the rest of the plumage is smutbrown, darkest on the back and wing-coverts, and lightest beneath; the wing-quills are black, with a white spot at their base, their outer pair is blue-splashed, the tail is black, with a white tip; the bill is deep yellow; and the legs are dull yellow. It is one of the commonest birds of India, where it is found in large numbers, being eminently sociable in its habits. It feeds chiefly on insects, grain, and fruit. It makes its nest in nooks and caves of walls and in holes in the walls of houses and ruins. The eggs, which usually number four or five, are pale bluish green in colour. It has a variety of notes, some musical and pleasing, others harsh. It is often domesticated, when it becomes patient and tame, and makes a good imitator of the human voice, in this respect excelling parrots. This bird was introduced into Mauritius to destroy the grasshoppers, which it did very effectually; but in its turn, when naturalized there, it became a pest through its ravages among fruit trees. — The name Hill Myna is given to those species of this genus which are the original races of birds belonging to the genus Enulas of Cuvier, or Gracula of Linnaeus, one from Southern India, another from Ceylon, a third from the Himalayas and Burma, and the last from Malaysia. They are birds of fine glossy plumage with prominent yellow wattles behind the ears. This genus contains thirteen species found in the oriental region as far as south-west China, Hainan, Java, and India.
in the Australian region in Flores, New Guinea, and the Solomon Islands.

Myopis. See Eye.

Myosin. See Globulins.

Myositis. See Forget-me-not.

Myrica, a genus of trees of the natural order Myrtales, to which belongs the Wild Clove or Wild Cinnamon of the West Indies (M. aérea), a handsome tree of 20 or 30 feet high. Its timber is very hard, red, and heavy, capable of receiving a fine polish, and much used for cogs of wheels. Its leaves have an aromatic cinnamon-like smell, and are used as astringents, and are used in sauces. Its berries are round, and as large as peas, have an aromatic smell and taste, and are used for culinary purposes. The leaves, berries, and flower-lights of _M. pimentoides_ have a hot taste and fragrant smell, and are also used for culinary purposes.

Myrica. See Canglerry.

Myriopoda (Gr., 'myriad-footed'), a class of terrestrial Arthropods with numerous and very unusual appendages. The head is distinct and bears a pair of antennae, while mandibles and maxillae form the true mouth-appendages. The legs themselves have six or seven joints, and end in a claw. Respiration is discharged by air-tubes or tracheae. The class includes two orders, which differ considerably among themselves: the Centipedes (Chilopoda), with flattened body, a pair of legs on each ring, the second pair behind the mouth with powerful poison-claws; and the Millipedes (Chilognatha), with cylindrical body, and two pairs of legs on most of the rings. The Centipedes are carnivorous, and their venemous 'bite' is sometimes dangerous; the Millipedes are destructively vegetarian, but otherwise harmless. Generally they avoid the light, and live in the ground, under stones, among moss, under bark, or in similar hidden habitats. A few have a quite ancestral-like simplicity of structure. Fossil forms appear in Carboniferous strata. See Centipede.

Myristicaceae. See Nutmeg.

Myrtaceae. See Ane-eater.

Myrtillidae, the followers of Achilles in the Trojan war, they were an old Thessalian race who colonised the island of Eginia. According to Greek legend Zeus peopled Thessaly by transforming the ants into men; hence myrtillids (myrtilleus = an ant').

Myrobalans, the astrigent fruit of certain species of Terminalia, trees of the natural order Combretaceae, natives of the mountains of India. _T. bellerica_ produces great part of the myrobalans of commerce of that name; the fruit is about the size of a nutmeg, very astrigent, with bitter kernels, to which intoxicating qualities have been ascribed. It is also said to be tonic, but is now scarcely used in medicine. The bark of the tree abounds in a gum, resembling gum-arabic, which is soluble in water and burns away in the flame of a candle. The kernel of the fruit is said to yield an oil which encourages the growth of the hair. Other forms of myrobalans are the Chelularia, the fruit of _T. chebula_; the Citrene, the fruit of _T. citrinus_; and the Indian, which are the small purple fruits of either or all of the preceding. They are all chiefly in request by tanners, dyers, and the manufacturers of ink. Embile myrobalans, the leaves of _Eugenia_ of the natural order Euphorbiaceae, are used in India as tonics and astringents, in tanning, and in the making of ink. For Myrobalan Plum, see Plum.

Myron, Greek sculptor, a native of Eleutherae, flourished about 430 B.C. He was a fellow-pupil of Phidias, and excelled in modelling athletes, animals, and figures in motion. His most cele-brated works were the 'Discobolus,' 'Ladas the Runner,' 'A Cow,' and 'Athene and the Satyr.' Copies have survived of the first and last only. Myron worked principally in bronze.

Myrrh (Hebr. myrrhe), a gum-resin produced by _Balsamodendron_ (q.v.) _myrrha_, a tree of the natural order Amyridaceae, growing in Arabia, and also in Solomon Islands. The myrrh-tree is small and shrubby, spiny, with white-gray bark, thinly-scattered small leaves, each consisting of three oborate leaflets, with obtuse toothlets, and the fruit a smooth brown ovate drupe, somewhat larger than a pea. Myrrh is exchanged for myrrh bark in oily yellowish drops, which gradually thicken and finally become hard, the colour at the same time becoming darker. Myrrh has been known and valued from the most ancient times; and was amongst the presents which the wise men from the East brought to the infant Jesus. (The 'myrrh' of Gen. xxxvii. 25, Heb. led, was probably Ladanum, q.v.) Myrrh appears in commerce either in tears and grains, or in pieces of irregular form and various sizes, yellow, red, or reddish brown. It is brittle, and has a waxy fracture, often exhibiting whitish veins. Its smell is balsamic, its taste aromatic and bitter. It is used in medicine as a tonic and stimulant, in disorders of the digestive organs, excoriations from the mucous membranes, &c., also to cleanse ulcers and promote their healing, and as a dentifrice, particularly in a spongy or ulcerated condition of the gums. It was much used by the ancient Egyptians in embalming. The best myrrh is known in commerce as Turkey Myrrh, but practically all myrrh comes either from Aden or from Bombay.

Myrtaceae, a natural order of exogenous plants, consisting of trees and shrubs, natives chiefly of warm, but partly also of temperate, countries. The order, as defined by the greater number of botanists, includes several sub-orders, which are regarded by some as distinct orders, particularly Chamalinaceae (in which are contained about fifty known species, mostly beautiful little bushes, often with fragrant leaves, natives of Australia and Tasmania), Barringtoniaceae, and Lecythidaceae. Even as restricted, by the separation of these, the order contains about 1300 known species. The leaves are entire, usually with pellidoid dots, and a vein running parallel to and near their margin. Some of the species are gigantic trees, as the Eucalyptus or Gum Trees of Australia, and different species of Metrosideres, of which one is found as far south as the Auckland Islands, in 50°S lat. The timber is generally compact. Astringeey seems to be rather a prevalent property in the order, and the leaves or other parts of some species are used in medicine as astringents and tonics. A fragrant or pungent volatile oil is often present in considerable quantity, of which
Oil of Cajeput and Oil of Cloves are examples. Cloves and Pimento are amongst the best-known products of the order. The berries of several species are occasionally used as spices in the same way as the true Pimento. A considerable number yield pleasant edible fruits, among which are the Pomegranate, the Guava, species of the genus Eugenia, and some species of the genus Myrta.

**Myrrh (Myrtus), a genus of Myrtaceae, the characteristics of which are well illustrated in the accompanying figure. The Common Myrtle (M. communis) is well known as a beautiful evergreen shrub, or a tree of moderate size, with white flowers. It is a native of all the countries around the Gulf of Genoa, and of the temperate parts of Asia, often forming thickets, which sometimes occur even within the reach of the sea-spray. The leaves are ovate or lanceolate, varying much in breadth. They are astrangent and aromatic, contain a volatile oil, and were used in medicine by the ancients as a stimulant. The berries are also aromatic, and are used in medicine in Greece and Italy. Myrtle wine is also made. Myrtle-bark is used for tanning in many parts of the south of Europe. Among the ancient Greeks the myrtle was sacred to Venus, as the symbol of youth and beauty, was much used in festivals, and was, as it still is, often mentioned in poetry. The myrtle endures the winters of Britain only in the mildest situations in the south. The Small-leafed Myrtle of Peru (M. micropyllea) has red berries of the size of a pea, of a pleasant flavour and sugary sweet-ness. Those of the Luma (M. luma) are also palatable, and are eaten in Chili, as are those of the Downy Myrtle (M. tomentosa) on the Neelgherry (Nilgiri) Hills, and those of the White-barred Myrtle (M. leucocarpa) in Greece and Syria. The berries of this species or variety are larger than those of the common myrtle. A very humble species of myrtle (M. nummularia) spreads over the ground in the Falkland Islands, as thyme does in Britain. M. Ugni, a native of Chili, was about 1865 highly extolled as a fruit-bearing shrub adapted to the warmest districts of Britain; but it proved unfit for open-air culture, though it fruits freely in an unhunted greenhouse. The fruit emits an aromatic fragrance which pervades the atmosphere around the plant continually, and the juicy pulp of the berries possesses a rare mixture of sweetness and spiciness which is very agreeable.

**Myrtle-wax. See Candleberry, Wax.**

**Myxus**, a genus of podophilous (stalk-eyed) crustaceans, of the order Stomatopoda, much resembling the common shrimps in form.

**Mysore**, or Mysore, a native state of Southern India, is surrounded entirely by districts of the Madras Presidency. The area is 24,700 sq. m. Pop. (1871) 3,655,412; (1891) 4,844,984. Mysore is an extensive tableland bounded by hills and deep ravines, and is divided into two portions, a little north of 13° N., by the watershed between the Kistna and the Kaveri rivers. Numerous isolated rocks (deargi), rising to 4000 or 5000 feet, are a peculiarity of the country, and stand the streams in their course from the mountains. The rivers are used for irrigation purposes, but are not navigable. The climate of the higher districts is during a great portion of the year healthy and pleasant. The annual value of the exports, chiefly betel nut and leaves, coffee, ragi, gram, cotton, piece-goods, castor-oil seeds, rice, and sugar, is above £1,200,000. The imports, consisting mainly of piece-goods, cloth, wheat, silver, gold, cotton, rice, silk, betel-leaves, and pepper, are over £1,500,000. The ruinous misgovernment of the native prince led the British to assume the administration in 1818; but in 1881 Mysore was restored to the native dynasty. The famine years (1876-78) told with great severity on that state. Chief town, Mysore; but the British headquarters were at Bangalore. For the history of Mysore, see HYDER ALI, TIPU SABIR, and JAHANGIR.

**The capital of the state, Mysore, is situated amid picturesque scenery on a dellcivity formed by two parallel ranges running north and south, 245 miles WSW. of Madras. A prosperous, well-built town, it has broad, regular streets, and substantial houses and public buildings. On a level site stands the fort, which encloses the rajah's palace; its chief object of interest is a magnificent chair or throne of fig-wood, overlaid with ivory and gold. Pop. (1881) 60,292; (1891) 74,048. The gold obtained by companies working at Kolar in the east of Mysore increased in 1875-79 from 15,500 ounces to 72,000 ounces per annum.

**Mystagogue (Gr. mystés, 'an initiated person,' and ago, 'I teach'), the name in the Greek religious system of the priest whose duty it was to direct the preparations of the candidates for initiation in the several mysteries, as well as to conduct the ceremonial of initiation. The same word is applied by the Christian mystics nearly as early as the 4th and 5th centuries to the catechists or other clergy who prepared candidates for the Christian mysteries, or sacraments, of baptism, confirmation, and the eucharist, especially the last.

**Mysteries** (Gr. from mioo, 'I close the lips or eyes'), also called Telestai, Origo, or, in Latin, Initia, designates certain rites and ceremonies in ancient, chiefly Greek and Roman, religions, only known to, and practised by, congregations of certain initiated men and women, at appointed seasons, and in strict seclusion. The origin, as well as the real purport of these mysteries, which take no unimportant place among the religious festivals of the classical period, and which, in their ever-changing nature, designate various phases of religious development in the antique world, is all but unknown. It does seem, indeed, as if the vague speculations of modern times on the subject were an echo of the manifold interpretations of the various acts of the mysteries given by the priests to the inquiring disciple—according to the lights of the former or the latter. Some investigators, themselves not entirely free from certain mystic influences (like Creuzer and others), have held them to have been a kind of mystic orb around a kernel of pure light, the bright rays of which were too strong for the eyes of the multitude;
that, in fact, they hid under an outward garb of mummeryn a certain portion of the real and eternal truth of religion, the knowledge of which had been derived from some primeval or, perhaps, the Mosaic revelation; if it could not be traced to certain definite sources in the remote past, yet it owed its peculiar character to an ever-regenerating and essentially eastern sources. To this kind of lazy talk, however (which we only mention because it is still repeated every now and then), the real and thorough investigations begun by Lobeck, and still pursued by many competent scholars in the latter day, have, or ought to have, put an end. There cannot be anything more alien to the whole spirit of Greek and Roman antiquity than a hiding of abstract truths and occult wisdom under rites and formulas, songs and dances; and, in fact, the ancients were anything but exclusive, either with respect to sex, age, or rank, in point of initiation.

It was only the speculative tendency of later times, when Polytheism was on the wane, that tried to symbolise and allegorise these obscure ceremonies. The very fact of their having to be put down in later days as public noises the in that herself speaks volumes against the occult wisdom inculcated in secret assemblies of men and women.

How it was that in the best times of Greece these mysteries had such a hold on such large numbers of people is a point about which there need be no question. Whether the Greeks had at any time had no revealed religion, no authoritative teaching on this point. Yet the religious sentiment required some external support for this aspiration, craved some confirmation of this hope. And pursued by many competent the men and women whose thoughts were fixed upon the next world found his or her faltering hope strengthened by the sympathy of thousands who were present from the same motives and in the same faith. That this is the secret of the mysteries is sufficiently proved by the resurrection of various gods which was most prominently set before the eyes of the initiated; and still more by such expressions as that of Pindar (fr. 137), "Blessed is he who has seen them before he goes below ground;" or of Sophocles (fr. 718), "All is good, lights who have been initiated before they die, for theirs is the lot of life, and evil is it with the others;" or of the chorus of the initiated in Aristophanes (Rham. 455), "We alone enjoy the holy light, we, who were initiated and led a life of godliness toward both kin and stranger;" or of the stone record (Ephest. arch, 188), "To the initiated death is not an evil: it is a gain."

The mysteries, as such, consisted of purifications, sacrificial offerings, processions, songs, dances, dramatic performances, and the like. The mystic forms of worship also, the censorship of Dracon, Lysanias, and other alike, the Litiaries, &c., were held holy secrets, and could only be communicated to those who had passed the last stage of preparation at the mystagogue's hand. The hold which the nightly secrecy of these meetings, together with the ceremonial, must have had upon minds more fresh and childlike than our advanced ages can boast of was increased by all the mechanical contrivances of the effects of light and sound which the priests could command. Mysterious voices were heard singing, whispering, and music; voices were heard in stately order, lights of various colours from above and below, figures appeared and disappeared; the mimic, the tonic, the plastic—all the arts, in fact, were taxed to their utmost to make these performances (the nearest approach to which, in this country, is furnished by transformation-scenes, or sensation-dramas in general) as attractive and profitable (to the priests) as could be. As far as we have any knowledge of the plots of these Mysteries, as also of other religious ceremonies generally brought the stories of the special gods or goddesses before the spectator—their births, sufferings, deaths, and especially their resurrections. Many were the outward symbols used, of which such as the Phallus, the Thymbra, Flowers, Baskets, Mystic Boxes, in connection with special deities, told more or less their own tale, although the meanings supplied by later ages, from the Neo- platonists to our own day, are various, and often very amazing. The most important Mysteries were, in historical times, those of Eleusis and the Thelemophorian, both representing—each from a different point of view—the rape of Proserpina, and Ceres' search for her; the Thelemophorian mysteries being also in a manner connected with the Dionysian worship. There were further those of Zeus of Crete (derived from an ancient demiurge, or partly Roman colonists took their Labers and Penates all over the antique world. The Eleusinian mysteries can be traced back to the 7th century B.C. (cf. Homerik Prytan to Demeter. l. 173 ff.) In the time of Herodotus (480-430 B.C., the period of Athens' highest power and of the Eleusinian mysteries' greatest fame, the number must have been much greater. When, towards the end of the classical periods, the Mysteries were reformed, the numbers of the most shameless kind, their days were numbered. The most sublime metaphysicians, allegorise and symbolise as they might, failed in reviving them, and in restoring them to whatever primitive dignity there might have once been inherent in their form.

See Lobeck, Apollonias (1829); Peller, in Panby's Essays, x. v.; Chr. Petersen, Der geheime Gottdienst (1848); Lehre, Populiare Aufsätze; Banmeister, Deuk- mader, u. v. Eleusinia; and P. Stengel, in Müller's Hand- buch der Klassischen Altertums-wissenschaft, vol. v. pt. 3.

Mysteries and Miracle-plays were dramas founded on the historical parts of the Old and New Testaments, and the lives of the saints, performed during the middle ages, first in churches, and afterwards in the streets on fixed or movable stages. Many were the late and miracle-plays from legendary subjects, but this distinction in nomenclature was not always strictly adhered to. We have an extant specimen of the religious play of a date prior to the beginning of the middle ages in the Christina Paschon, assigned, somewhat questionably, by Gregorovius (Dithyrambik, 221) to Cretan-Greek 4th-century Greek. Next come six Latin plays on subjects connected with the lives of the saints, by Hroswith (c. 920-961), a nun of Gandersheim, in Saxony, which, though not very artistically constructed, possess considerable dramatic power and interest; they were discovered by Konrad Celtes and by him first published in 1501 at Nuremberg. The performers were at first the clergy and choristers; afterwards any layman.
Mysteries

Many of the old religious plays sprang from a third class of religious plays, called *Moralities*, in which allegorical personifications of the Virtues and Vices were introduced as *dramatis personae*. These personages at first took part in the play along with the scriptural or legendary characters, but afterwards entirely superseded them. The oldest known English compositions of this kind are of the time of Henry VI.; they are more elaborate and less interesting than the miracle-plays. Morailities continued in fashion till Elizabeth's time, and were the immediate precursors of the regular drama.

The mystery-play was also regular in France, Germany, Spain, and Italy as in England; and indeed some of the *pastoreles* still acted among the Basques (q.v.) are mere survivals. A piece of the kind yet extant, composed in France in the 11th century, is entitled the *Mystery of the Wise and Foolish Virgins*, written partly in Provençal, partly in Latin. A celebrated fraternity, the Confrérie de la Passion, founded in Paris in 1350, had a monopoly for the performance of mysteries and miracle-plays, the exhibition of each of which took several days. Many of these are still extant.

It is a mistake to suppose that the hostility of the Reformers was what suppressed these exhibitions. The fathers of the Reformation showed no unfriendly feeling towards them. Luther is reported to have said that they often did more good and produced more impression than sermons; and Bishop Edse's *Briefe County of John Brugge* (1538) is an onslaught on the friars. The most direct encouragement was given to such plays by the foundeers of the Swedish Protestant Church, and by the earlier Lutheran bishops, Swedish and Danish. The utmost enthusiasm of the drama of the kind is ascribed to Gratins. In England, the Reformers were content that they received was from the rise of the secular drama; yet they continued to be occasionally performed in the times of James I. and Charles I., and it is well known that the first sketch of Milton's *Paradise Lost* was a sacred drama, where the opening speech was Satan's Address to the Sun.

Mysticism

A degenerate relic of the miracle-play may yet be traced in some remote districts of England, where the story of St George, the dragon, and Beelzebub is rudely represented by the peasants. Strange to say, it was in the Catholic south of Germany, where these uncultivated peasants knew nothing of most of their old religious character, that the severest blow was levelled against them. In 1779 a manifesto was issued by the Prince-archbishop of Salzburg, condemning them, and prohibiting their performance, on the ground of their licentious mixture of the stepping beyond the bounds of narrative acting in the serious parts, the distraction of the lower orders from more edifying modes of instruction, and the scandal arising from the exposure of sacred subjects to the ridicule of freethinkers. This ecclesiastical denunciation was followed by vigorous measures on the part of the civil authorities in Austria and Bavaria. One exception was made to the general suppression. In 1633 the villagers of Ober-Ammergau (q.v.), in the Bavarian highlands, on the cessation of a plague which desolated the surrounding country, had vowed to perform every tenth year the play which the people had created in gratitude, and as a means of religious instruction; a vow which had ever since been regularly observed. The plauds of a deputation of Ammergau peasants with Maximilian of Bavaria saved their mystery from the general condemnation, on condition of every-thing that could offend good taste being expunged.

It was then and afterwards somewhat remodelled, and is perhaps the only mystery or miracle-play which has survived to the present day—taking place every ten years (1570, 1886, 1890, &c.). The inhabitants of this secluded village, long noted for their skill in carving in wood and ivory, and a deep regard for artistic cultivation with perfect simplicity. Their familiarity with sacred subjects is even beyond what is usual in the alpine part of Germany, and the spectacle seems still to be looked on with feelings much like those with which it was originally conceived. What would elsewhere appear impious, is to the alpine peasants devout and edifying. The parson of Christ considers his part an act of religious worship; he and the other principal performers are said to be selected for their holy life, and consecrated to their work with prayer. The players, who are all villagers, are directed by an archdeacon, or, in place of an archdeacon, by a group of villagers, who, though they have no artistic instruction except from the parish priest, act their parts with no little dramatic power, and a delicate appreciation of character. The New Testament narrative is strictly adhered to, the only legendary addition to it being the St Veronica handkerchief. The acts alternate with *tableaux* from the Old Testament and choral odes. Many thousands of the peasants are attracted by the spectacle from all the parts of Tyrol and Bavaria, among whom the same devout demeanour prevails as among the performers. The plays only from subjects in legendary or sacred history, are not unfrequently got up by the villagers around Innsbruck, which show a certain rude dramatic talent.

Hasse, trans. by Jackson (1880); A. W. Pollard, *English Miracle-plays*, *Moralities*, and *Interludes* (1890); the classified list of *References for Students of English Drama plays and Mysteries* (1897), compiled by S. A. Stoddard (Berkely, U.S.A. 1887); and, for the passion-play at Oberammergau, now by Seguin, Tweedie, Farrar, and others.

Mysticism is not such a definite system of thought as a tendency of religious feeling, cher-
lished more or less at different periods in most religions by individuals or groups: the essential element being the effort to attain to direct and immediate communion with God or the divine. The tendency appears in the Mysteries (q.v.) of the Gnostics, those found in the情形 contemporary of various Hindu sects, in Sufism, and is the most prominent feature in Neoplatonism and some of the Gnostic systems. But it is also especially to Christian writers of the middle ages that the name of mysticism is to be given, one of the earliest being Pseudo-Dionysius; the Gnostics, and the Brethren of the Common Life (to whom Thomas à Kempis belonged), and the Anabaptists. Less theological and more philosophical are Paracelsus, Bruno, Campanella, Jacob Boehme, Schelling, and Swedenborg. In England, the system was most developed; and some of the Cambridge Platonists like Henry More were to some extent mystical in their religious teaching. Millenarianism has produced several types; from Jansenism sprang the Conviservatories. In modern Catholicism St. Thomas More must rank among the mystics, and Bourignon may be specially mentioned. Most of them are discussed in separate articles.

See Boheme, Eckhart, &c., in this work; also Illuminati, Rosicrucians, Theosophy; Vaughan, Hours with the Mystics (1855); 3d ed. 1860; Du Prél, The Philosophy of Mysticism (trans. by Massey, 1889); and German works on the subject by Görres (1846), Heßlerich (1842), Noack (1853), Preger (1881).

Mythology. A myth is a story told about gods or heroes. Mythology is a term sometimes applied to the collection of deities and gods, sometimes to the scientific study of myths. Mythology in the latter sense of the term has for its object not to ascertain why men believe in gods—that is rather the business of the science of religion—but, granted the belief, why men tell these (somewhat) extraordinary stories about them. The first nation to busy itself with this enquiry was the nation whose mythology had the most luxuriant development, the Greeks. From very early times they started their enquiry with the assumption that there must be something behind the myths as known to them—that there was some meaning in a myth. Thus far, they were as regards most myths quite right. The mistake, however, which the Greek philosophers who undertook to recover the original meaning of various myths made was that they imagined the authors of these myths to be, like themselves, prone to the use of allegory. They imagined that not only was there a meaning concealed behind myths, but that that meaning had been intentionally concealed, and that myths were the vehicles by which philosophical teaching had been conveyed, and in which it might still be detected. Myth was idealized and allegorized.

The particular branch of philosophy supposed to be veiled by mythology depended on the taste of the particular mythologist. Anaxagoras discovered psychological teaching behind the veil; Empedocles discovered a doctrine of union and division; Heraclitus discovered a form of self-regulation; the religions of the East discovered a form of self-purification; the Gnostics discovered a form of salvation; the Stoics discovered a form of friendship. This was the case with Heracleides, who first attempted to demonstrate the identity of the gods and the serpent. The object of this error was to reconcile the necessity not only of throwing aside our modern, civilised, artificial ideas, but also of,

And speaking generally, we may say that from that day to this the magic mirror of mythology has never failed to show to every enquirer that which he wished to see in it. The next attempt at interpretation, which also proceeded from Greece, was to strip mythology of its mystery. In the hands of the Greeks, mythology was reduced to a system of arbitrary fictions. The attempt to make mythology consist of what had not been intended by the authors of the myths, has not been altogether successful. It is interesting to note that in India an independent attempt was made by the Alhíslakí school to explain the mythology of the Vedas as history elapsed in the garb of the supernatural. The two modes of activity were, as has been already described—the allegorical and the Euhemeristic—continued to be the only methods applied throughout Rome and Christian times to the present century, nor can they be said to be wholly extinct even now. At Rome the States, developing systematically what had been rather suggested than definitely formulated by Empedocles, endeavoured to explain all myths as but allegorical descriptions of physical facts. They failed, however, to explain just those myths which most required explanation. Modern men of the Spirit of the Age have given up the attempt to apply the elementary and bestial myths, for examples of which we may refer to Vol. V. p. 385 of this work. Their failure was the more remarkable inasmuch as in India the same key had been applied by the native grammarians with considerable apparent success; but it has required experience derived from a study of all the scientific methods of investigation, before it has been possible to prove and illustrate. It led to a thorough investigation of the assumptions on which the allegorical theory was based; and an era in the history of mythology as a science is marked by the demonstration given by Lobeck in his Aglaophamus (1829), of the utter untenability of these assumptions. What is implied in any theory which explains myths as truths conveyed in the form of allegories is the existence of a caste or class of priests or philosophers, possessing a recondite knowledge and teaching it by means of parables. Now the example of such a society is not a matter which requires to be proved, and of which the proof must satisfy the canons of historical criticism. And it may safely be said that there is absolutely no evidence whatever to show that such a class ever existed amongst the Greeks or any other Indo-European nation.

The establishment of this negative conclusion by Lobeck paved the way for the next step forward in the science of mythology. Scholars had hitherto assumed that the authors of myths were men of learning, and that a sort of magic art of this error, the next step was to recognise the necessity not only of throwing aside our modern, civilised, artificial ideas, but also of,
endeavouring to see the myths in the light in which they presented themselves to the Homeric era. Here, however, the necessity manifests itself, after the time of Lobecck, in Grote, from whom the quotation in the last sentence is made, Lehrh (Gott, Götter, and Dämonen), and Renan (Études de L'histoire Religieuse). Now, if we try to see myths as primitive man saw them, on this thesis alone do the Greek of Homer's time or Hesiod's Aphrodite must have presented herself as the ideal of female beauty, Demeter as the perfect type of motherhood, and so on. Thus far it was thought, by Grote and others, possible to go in the way of interpretation: to the nature of mythological personages and the times they are given to anthropomorphism. But to go further and try to explain not only the individual figures of the gods, but the relations in which those figures are represented by myth as standing to each other, was, by a natural reaction against the exploded system of allegorical interpretation, considered futile. Primitive man is but a child; he lives in a world of dreams and fancies which are to him as real as the waking world of facts. As for coherence or meaning in what he chose to dream about his gods, you may as well undertake to decode the music the bells say. The imagination knows no law, or at the most is subject only to the laws of poetical and aesthetic consistency. It is vain to endeavour to go beyond the myth, or behind it. It is like the curtain of Zeusis, which was itself the picture. There is nothing behind it. This, as we have said, was a natural reaction, but the pendulum swung too far. No one at the present day would think of denying that in many cases there is something behind the veil—that most myths have a meaning of some kind. Nor would any one now admit that myths possessed poetic or aesthetic consistency; on the contrary, one of the problems of scientific mythology is to explain the inconsistency of feeling which is to be found in myths relating to the same subject, to explain, for instance, the repulsive origin attributed by mythology to Aphrodite, the type of feminine beauty, or the amount carried on by Demeter, the ideal of motherhood, in the shape of a mare, with Poseidon.

A partial solution of this problem was afforded by the brothers Grimm (q.v.), whose labours mark a new era in mythology. While collecting their famous records of the oral tradition, they were forced to the conclusion that many a tale which had hitherto only been known in a literary form had existed orally long before it had been put on paper or shaped into verse, and the further inference from this became the wide-reaching conclusion that mythology was not, as the allegory theory had falsely taught, the work of the superior few, but the production of the people. It was the way in which the many expressed their religious feeling. It was their only mode of expression, and it was then exclusively. The current of mythologies is then, even from the lower classes of society to the upper. Here we have an explanation of the incongruity existing in the myths told of Aphrodite or Demeter, for instance; for myths could not be perpetually retold in one generation after another without being reshaped to suit the changing condition of the people. The old was thrown off, and the new was put on. But it will be also noticed that, granting that the current of mythology is upwards from below, we are no nearer an answer to the question, Why do men tell the extraordinary stories they do tell about their gods? The quarter, however, in which an answer to this question might be looked for was indicated by Grimm.

One and the same myth may be found, in different forms, amongst different Aryan peoples (see Vol. I. p. 471), and although some such myths may have been borrowed by one people from another, the question of their connexion manifests itself, after the time of Lobecck, in Grote, from whom the quotation in the last sentence is made, Lehrh (Gott, Götter, and Dämonen), and Renan (Études de L'histoire Religieuse). Now, if we try to see myths as primitive man saw them, on this thesis alone do the Greek of Homer's time or Hesiod's Aphrodite must have presented herself as the ideal of female beauty, Demeter as the perfect type of motherhood, and so on. Thus far it was thought, by Grote and others, possible to go in the way of interpretation: to the nature of mythological personages and the times they are given to anthropomorphism. But to go further and try to explain not only the individual figures of the gods, but the relations in which those figures are represented by myth as standing to each other, was, by a natural reaction against the exploded system of allegorical interpretation, considered futile. Primitive man is but a child; he lives in a world of dreams and fancies which are to him as real as the waking world of facts. As for coherence or meaning in what he chose to dream about his gods, you may as well undertake to decode the music the bells say. The imagination knows no law, or at the most is subject only to the laws of poetical and aesthetic consistency. It is vain to endeavour to go beyond the myth, or behind it. It is like the curtain of Zeusis, which was itself the picture. There is nothing behind it. This, as we have said, was a natural reaction, but the pendulum swung too far. No one at the present day would think of denying that in many cases there is something behind the veil—that most myths have a meaning of some kind. Nor would any one now admit that myths possessed poetic or aesthetic consistency; on the contrary, one of the problems of scientific mythology is to explain the inconsistency of feeling which is to be found in myths relating to the same subject, to explain, for instance, the repulsive origin attributed by mythology to Aphrodite, the type of feminine beauty, or the amount carried on by Demeter, the ideal of motherhood, in the shape of a mare, with Poseidon.
form a literary mythology which is nothing like so near to the myth-making stage in the history of a people as are many of the popular traditions of the peasantry of Europe. On the other hand, although Max-Müller and his school have been guilty of many offences against the canons of comparative philology in their desire to identify the names of mythological figures, Grimm undoubtedly has gone too far in asserting that comparative philology lends no support whatever to the belief that the Aryan possessed any gods at all. Zeus, Aurora, and Agni may safely be said to have been known to the Aryan, and to have been attached to them in all the events of the mythological life.

Another series of attacks has been made upon the Kuhn and Müller school on the ground that, if the comparative method is to be applied, it should be applied to the whole of the facts, and not to one particular section of them. In other words, we must not confine ourselves to Aryan myths, but must open our eyes to the fact that nearly every Aryan myth can be paralleled by similar tales from the remotest quarters of the globe. No explanation which explains only a part of the phenomena and leaves other exactly similar phenomena unexplained can be the final explanation. Obviously, therefore, it is impossible to find the key to all the mythologies in any peculiarity of language, for such peculiarity or "disease" would only affect the mythology of the nations speaking that language or family of languages. The mythologist has not only to ask himself the question why men tell their extraordinary tales about the gods, but also the question why do they all tell the same sort of story, no matter what race or clime they belong to.

The theory that all myths are derived from a common centre, from the very fact of existence of all mankind, the face of the earth by borrowing, would explain the similarity in the myths; but, until that theory is more fully elaborated than it is at present, the field is held by a theory of mythology of which the most distinguished champion in England is Mr. Andrew Lang (q.v.). It is briefly, that myths are survivals from a primitive stage of culture through which all races pass, and in which they much resemble each other. Ez einand ezemad. Primitive man, whether of the stone age or on this side of the world on the other side of his present development in much the same way; and no one thinks of accounting for the resemblance between the implements thus manufactured by any theory of borrowing or of common descent. It is obvious that the same causes acting on the same organisms produce similar results, and this is as true of mental and moral culture as of material culture. Here, too, we have the explanation of the strange nature of many myths; what seems brutal to us does not seem brutal to the savage. There is therefore nothing surprising in the fact that the gods and heroes of the savage are, like himself, savages. Above all, the same problems presented themselves to primitive peoples in all parts of the world, and were solved by the aid of the same analogies. What was the origin of man? of the world? What causes rain? Why does the sun behave as he does? Why are certain customs observed? The answers which commanded themselves to primitive man constitute mythology. At the same time there is no reason to believe that primitive man was not as fond of hearing and telling stories as civilised man is of reading novels. And though most myths may be the explanations which were invented to explain what seemed to primitive man to need explanation, some myths probably were from the beginning designed solely for the gratification of the imagination.

In addition to the works of Creuzer, Lobeck, Grote, Lehrs, Rosan, Grimm, and Gruppe referred to, see Max-Müller's various works, and particularly his Biographies of Words; Mannhardt, Wald and Feldkultur; Schneider, Prehistoric Antiquities of the Aryan Peoples; E. B. Tyler. Early History of Mythology in Primitive Culture; A. Lang. Custom and Myth and La Mythologie (Paris, 1886); Canon Taylor, Origin of the Aryan; Chantepie de la Saussaye, Religionsgeschichte; C. Petersen, article Mythologie in Ehrich and Gruber; L. D. Dahl, Griechische Mythologie der Griechen alter, Mythologien der Griechen und Römer, Mythologie de la Grèce antérieure; and Roscher's Lexikon der Mythologie. See also the articles in this work on such mythologists as Euhemerus, Cox, Gubernatis, Lang, Max-Müller; those on the several gods; and the following: Ancestors, worship of. | Domestology. Animals, worship of. | Divination. Animism. | Egypt (religion). Auguries. | Greece (religion). Beat-fables. | Homer. Bilateral. | Homer. Consonony. | India (p. 104). Myxcedema is the name generally accepted for a diseased condition first described by Sir William Gull in 1873. It occurs in adults, generally females, and is characterised by a thickening of the subcutaneous tissue, most noticeable in the face (which becomes enlarged, swollen-looking, and expressionless) and the hands, with a simultaneous dulling of all the faculties and slowing of the movements of the body. A precisely similar condition occurs in many cases where the thyroid gland has been removed for disease. Myxectenma is very slow in its progress. It greatly resembles cachexia, and the mental condition is much less affected. In 1890-91 Horsley and others treated cases successfully by grating in the thyroid gland of a calf, or by injecting the juice of animal thyroids. Since then remarkable success has been attained by giving the patients calves' thyroids to eat, or administering the extract by the mouth. The improvement, which is swift and marvellous, lasts only so long as the sufferers continue to take the remedy. See monograph by A. M. Wilson (1893).

Myxomyceetes, or MYCETOZOA, a class of very simple organisms, sometimes claimed by botanists as fungi, and by zoologists as primitive Protozoa. They live on damp surfaces exposed to air, especially on rotting wood, and feed on organic debris. They form composite masses or plasmodia, in which numerous units are fused, or in rare cases simply combined in close contact. On the margins of such a mass amoeboid processes of living matter flow in and out, with streaming internal movement, and the plasmodium spreads towards moisture, food, and warmth, or away from the light. Drought, cold, or scarcity of food produce a dormant encysted stage. At other times part of the plasmodium divides into spores, each enclosed in a coat, which bursts and liberates a swarm spore, sometimes flagellate, always eventually like a little ameba. A number of these minute amoebae unite to form the plasmodium from which we started. About two hundred species have been described. See: Fungus, De Bary, Die Mycetozoen (1864); Zooph, Die Schleimpilze, in Schenk's Botanik, iii. (1887).

Mzensk, a town in the Russian government of Orel, 200 miles SSW. of Moscow. Pop. 15,067.
the fourteenth letter in our alphabet, is derived from the hieroglyphic sign for water (see Alphabet). When taken over by the Phoenicians it was called nun, 'the fish.' The earliest Greek form was Ν, which afterwards became N. Our script form, Ν, is derived from the old Roman cursive. The sound of n is defined as a nasal dental. It is produced when the organs are in the position for pronouncing d, and the breath is allowed to pass into the nose. Hence n attracts d, as in exposed from exposo, sound from sonus, or in thunder and hind from Old English thanor and hine. Our two nasals m and n also interchange according to the nature of the following consonant. If it is a labial m changes to n, as in hemp from Old English hune, or comfort or comfortare; but if it is a dental m changes to n, as in aunt from Old English aemate, or count or computare. We also find an intrusive n before gutturals and dentals, as in nightside from Old English niddelde, messenger from messenger, passenger or passer from passer, or lantern from laterna.

**Naas**, a garrison town of Kildare county, Ireland, 20 miles SW. of Dublin by rail; pop. 3508. Once the capital of Leinster, Naas obtained charters from Henry V., Elizabeth, and James I., but was disfranchised at the Union.

**Nabatæans**, a people of northern Arabia, generally considered to have been of pure Arab blood, though some authorities, identifying them with the Ishmaelite tribe of Nebiatha, regard them as having been closely akin to the Edomites. They took possession of the country once occupied by the Edomites; and in the beginning of the 5th century B.C. they were one of the most powerful amongst the Arab tribes, warlike, with a force of 10,000 fighting men, nomadic, and busy carriers of merchandise between the East and the West. In 312 B.C. Antigonus, the general of Alexander, made an attack, unsuccessful, upon their desert fastness of Selma or Petra (q.v.). By the 1st century B.C. they had shaped their power into a kingdom; in the time of St Paul their king Arethas, who died in 40 A.D., after a reign of forty-eight years, was master of Damascus and Cades-Syria. They were in antagonism successively to the Syrian monarchs, the Macedonian rulers of Juden, and the Romans, but eventually acknowledged the supremacy of these last. Nevertheless Trajan, in 105, captured their stronghold and put an end to their kingdom. They possessed a certain measure of culture, derived from the Syrians. The language of their coins and inscriptions is Aramanic. See Charles Doughty, *Documents Épigraphiques recueillis dans le Nord de l'Arabie* (1884), and books cited at Edom.

**Nabhi**. A Sikh principality under the political control of the Punjab, sis-Sultej, to the E. of Patiala and S. of Lodiana; area, 928 sq. m. Pop. 201,821.

**Nabulis**, corrupted from the Greek Neapolis, the ancient Shechem, a town of Palestine, stands on the highest part of the pass, between Mounts Ebal and Gerizim, that leads from the Mediterranean to the Jordan. In the same valley or gap are Jacob's Well, the Tree of the Sanctuary, and Joseph's grave. At first a Canaanite city, it was destroyed by Alâmelech, a son of Gideon the Judge. Here Rehoboam was crowned king of Israel. The place became the religious centre of the Samaritans (q.v.). The Greek city gave birth to Justin Martyr, and suffered much during the Crusades. See Memoirs of Palestine Exploration Fund, vol. ii.

**Nabool**, an Anglo-Indian corruption of the word Nusub ('deputy'), was the title belonging to the administrators of provinces under the Mogul empire. The title was continued under the British rule, but it gradually came to be applied generally to natives who were men of wealth and considered to be the zenith, nadir, and more of the essence critically to those who, having made great fortunes in the Indies or in foreign parts generally, return to their native country, and live there in oriental splendour.

**Nabonassar**. See BABYLONIA.

**Nachtigal**, Gustav, German traveller, was born 23d February 1834, at Kielstedt, between Magdeburg and Wittringen, studied medicine, and served as army surgeon until 1863. In that year he went to North Africa, suffering from a chest disease. In 1868, through the influence of Rohlfs, he was selected to carry presents from the king of Prussia to the sultan of Bornu. Starting from Tripoli in 1869, he travelled by way of Fezzan and Tisesti to Bornu, made excursions into the states of Borgo and Bagirmi, and returned home by way of Wadjai, Dar-Fur, Korodfan, and Cairo, where he arrived on 22d November 1874. This long and successful journey, in the course of which he visited, the first of Europeans, the native states of Tisesti, Borgo, and Wadjai, put him in the forefront of the savant-travellers. His vast collection of most valuable information was written down in the three vols. of *Sahara und Sudan* (1879–80). In 1884 Nachtigal was commissioned to annex for Germany Togoland, Cameroon, and Lüderitzland (Angra Pequena) on the west coast of Africa. He died on the return journey off Cape Palmas, 19th April 1885, and was buried on that rocky promontory; but in 1887 his bones were removed to German soil in the Camerons. See *Dorothea Berlin's Erinnerungen an Nachtigal* (1887).

**Nacre**. See PEARL (mother of).

**Nadir** (Arabic ناصر), that point in the heavens which is diametrically opposite to the Zenith (q.v.), so that latitude and longitude are in one straight line. The zenith and nadir form the poles of the Horizon (q.v.).

**Nadir Shah** of Persia, the Conqueror, belonged to a Turkish tribe, and was born in Khorassan in 1688. He entered the service of the governor of Khurassan, and soon obtained high promotion; but, having been degraded for some offence, he betook himself to a lawless life, and for several years was the daring leader of a band.
of 3000 robbers, and gradually extended his terri-
torial authority. Persia was at this time ruled by
Ashraf, an Afghan, whose grinding tyranny and
cruelty produced in the mind of every Persian a
deathly hatred of the very name Afghan. Nadir
having avowed his intention of expelling the hated race from the country, and putting the old
dynasty, its renum bers flocked to his standard, and
Meshed, Herat, and all Khorassan were speedily
reduced. Ashraf, signally defeated in several en-
gagements, fled before the avenger, who, with a
celebrity only equalled by its thoroughness, purged
Persia of her invaders, and put an end to half a
century of misgovernment. He then returned with
Nadir, the last of the great Safawids, to conquer
and subdue that vast and populous country.

The name when used without qualification, a
vascular nevus or overgrowth of capillary blood-
vessels is generally meant, and the term is used
of the tumors which almost always occur in
(children. The smallest form is sometimes called
port-wine stain, and is sufficiently described by the
name: there is just so much overgrowth as to pro-
duce a deep red discoloration, without appreciable
swelling of the part affected. Frequently the
abnormal tissue forms a distinct tumour, either in
the skin, when it is of a dark red colour, or beneath
it, when it may sometimes be recognised by a blue
or purplish tinge. The most frequent situations of
these vascular nevi are the skin and subcut-
naneous cellular tissue of the face and head; but
they may occur elsewhere. The popular belief
is that they are caused by the longing of the
mother during her pregnancy for a lobster, or
strawberry or raspberry, or some other red-coloured
article of food, and that the influence of her
mind has impressed upon the fetus a more or
less vivid resemblance of such a food, hence the
name of mother-spot. Sometimes these
 tumours waste away spontaneously, and give no
 trouble; but frequently they increase rapidly,
invade the adjacent tissues, and ulcerate or slough,
and thus become dangerous to life by hemorrhage.
When these tumours do not show a tendency to
increase no treatment is necessary, except to
remove the disfigurement. When treatment is
desirable many different methods may be employed,
according to the form and situation of the tumour:
e.g. removal by knife or ligature; coagulation of
the contained blood by electrolysis; production of
inflammation by application of caustics or,
in infants, by vaccination upon the nevus.

Nagiya, capital of a district in Bengal, on the
Bhagirathi River, 63 miles N. of Calcutta; pop.
14,105. It was the residence of the last independent
Hindu king of Bengal (till 1205).

Neuvius, Gneas, with the exception of Livius
Andronicus, the earliest of the creators of Latin
literature, was born, probably in Campania, about
265 B.C. In his youth he served in the first Punic
war, and, having been wounded at Rome, was
disabled, and restored to public life by
Tiberius Gracchi. In the year 177 he
recovered, and with the young Cnidos, he
was for thirty years. Of his life we know little, save
that he was very decidedly attached to the plebeian
party, and in his plays satirised and lampooned
the Roman nobles with all the virulence and
indiscretion of a hot-blooded and unsparing Campanian—that
Gaison of ancient Italy. He incurred the especial
hostility of the Metelli, and was imprisoned at
their instance, as we learn from a passage in the
Miles Gloriosus of Plautus. He was ultimately
successful in retiring to Utica in Africa, where he died
after a few months. Besides his dramatic writings, comprising
both tragedies and comedies, he wrote an epic
poem, De Bello Punico, in the old Saturnian metre.
His work bore the stamp of the national genius,
and its vigour and invention gave pleasure to Cicero
and to Horace. Only a few very unimportant
fragments remain of the various editions which have
been formed of them. The most
recent edition is that of Vahlen (1854) and
Ribeck, Seneca Poesis Romana.; Römische Frag-
mente (2d ed. 1871-73). See also Sellar's Poetae of
the Roman Republic, and Ribeck, Die Römische
Tragöde (1875).

Neurus (Lat., 'a mole'; known variously as
mother-spot or birth-mark) is a congenital mark or
growth strictly on a part of the skin. The most
frequent form is the pigmented nevus, or mole.
This may be simply a darker pigmentation of a
circumscribed portion of skin; or the pigmented
skin may be thickened and rough as well, and is
often thickly covered with hair. Moles do not
seem to increase, and do not need to be treated
unless for the sake of appearance. In that case,
removal by knife or destruction by caustics must
be resorted to.

Nagasaki, seaport of Kyushu, Japan, and
for more than two centuries the only gate of
communication for that empire with the outer
world. Its harbor is ample for its needs, and
inlet about 3 miles in length. Near its head,
below the native town, is the low, fan-shaped
island of Deshima, where the Dutch factory was
situated. From 1637 to 1859 the Dutch traders
were the only human visitors to the
monastery of their lives being varied by the arrival
of the yearly ship from Batavia, and the annual
journey to Yedo, when presents were made to the
Shōgun. Chinese traders were also permitted to
carry on a limited trade. In 1859 Nagasaki became
one of the five open ports. The great Takashima
coil-mine, situated on an island 8 miles seaward of
the entrance to the harbour, serves to give importance to Nagasaki as a coastal station. Nagasaki also possesses a fine dockyard and patent slip. The foreign settlement is situated on the flat land and the hills that surround the bay. Catholic Church has a strong mission here, and in one of the valleys in the neighbourhood is a community of historical native Christians. Protestant missions are represented by the English Church Missionary Society, and the American Methodist, Episcopal, and (Irish) Reformed Church missions. At the mouth of the harbour is the small island of Pappenborg (Takakubo), from which 300 Christians are said to have been hurled in the frightful persecutions of the 17th century. Pop. (1895) 72,321.

Nagina, a town in the North-west Province of India, 48 miles NW. of Moradabad. Pop. 20,503.

Nagpur, a city of British India, the seat of administration for the Central Provinces, 450 miles E.N.E. of Bombay by rail. It lies enshrouded in trees, has several handsome tanks, gardens, and temples, and extensive suburbs, but is not a healthy city, the mean temperature being 78° F. Fine cloth fabrics are woven, and there is an active trade in the products of the cotton gardens. Here, on the 26th and 27th November 1817, a British force of 1350 men, commanded by Colonel Scott, defeated a Mahrratia army of 18,000 men. Pop. (1872) 84,441; (1891) 98,300; (1901) 117,014. The district of Nagpur has an area of 3843 sq. m. and a pop. of 2,982,507. Chota Nagpur (q.v.) is a division of Bengal.

Nag's Head Consecration, a lunatick legend first circulated by Roman Catholics forty years after the event with respect to Archbishop Parker's consecration (1559), to the effect that he divined in the name and regular manner in the Nag's Head Tavern, Cheshpide. The facts of the case are that the election took place in the chapter-house at Canterbury, the confirmation at St Mary-le-Bow's Church in Chespide, and the consecration in the chapel of Lambeth Palace, the consecrating bishops being Burton, Scory, Coverdale, and Hodgkin.

Nahant, a summer-resort on a small, rocky peninsula of Massachusetts Bay, 12 miles NE. of Boston. Pop. (1900) 1152.

Nahun. The seventh of the twelve minor prophetic books of the Old Testament is included in the collection of Nineveh, the life of Nahum the Elkoshite. The opening verses speak (i. 2-8) in general terms of the certainty and awfulness of the divine judgment against the enemies of God, and of his unrelenting goodness to those who put their trust in him; these principles are then applied (i. 9-15) on the one hand to some power, not yet named, that imagineth evil against the Lord; and, on the other, to Judah (i. 15), who, though now afflicted, is to be afflicted no more. The second chapter opens with a rapid sketch of a military armament—the red shields, scarlet uniforms, flashing chariots, brandished spears—hurriedly summoned from the defensive war; then Nineveh, first named in ii. 8, is seen as a ruined site which an inundation has swept bare, and the great spoil of the ‘dwelling of the lions’ is indicated rather than described. The subsequent picture of the capture of Nineveh—i.e. not later than 605 B.C. The explanation of i. 11 by former interpreters as alluding to Sennacherib is thus excluded; the reference must rather be to some actual or threatened invasion of Judah in the reign of Manasseh, and most probably to that of Assurubalit about 647 B.C., in which Manasseh was not himself active. The prophecy is written in classical Hebrew, and is characterised by a bold and vivid originality of style, if also by a conscientious sometimes bordering on obscenity; in more than one expression it has been thought that the writer betrays personal acquaintance with Ninevite airs, and it is conjectured that he may have been either an Israelite of the northern kingdom who in early youth had been deported after the fall of Samaria, or a Judahite who had been carried captive along with Manasseh. Of his personal history nothing is actually known; the name, which is not a very common one, reappears in Luke, iii. 25, and in the name of the Galilean Capernam (‘village of Nahum’). He is described as a native of Elkesh, by which perhaps is to be understood the modern El-Kusheh, near Hannah in Upper Galilee, though others think it is Al-Kush near Musul, on the left bank of the Tigris, where the grave of the prophet has been shown since the 16th century. See commentaries by O. Strassm. (1853), C. A. Blomquist (1853), F. Gilly (1800), M. Breitenicher (1861), L. Reinike (1867), and E. Mahler (1880), and works mentioned under Hosea.

Naiads. See NYMPHS.

Naihni, a town of Bengal, 239 miles NW. of Calcutta by rail. Pop. 21,925.

Nails are flattened, elastic, horny plates, which are placed as protective coverings on the dorsal surface of the terminal phalanges of the fingers and toes. Each nail consists of a root, or part concealed within a fold of the skin; a body, or exposed part attached to the surface of the skin; and a free anterior extremity called the edge. The skin below the root and body of the nail is termed the matrix, from its being the part from which the nail is produced. This is thick, and covered with highly vascular papillae, and its colour is seen through the transparent horny tissue. Near the root the papillae are smaller and less vascular, and the portion belonging to this part is of a whiter colour; from its form, this portion is termed the lunula. It is by the successive growth of new cells at the root and under the body of the nail that it advances forwards, and maintains a due thickness, whilst at the same time the portion surrounding in a proper eonnection is ensured. The chemical composition of the nails is given in the article HORN, to which class of structures they belong. According to the observation of Bean, the finger-nails grow at the rate of about two-fifths of an inch in a week, while the toe-nails only grow with about one-fourth of that rapidity. When a nail has been removed by violence, or has been thrown off in consequence of the formation of matter (pus) beneath it, a new nail is speedily formed, provided the matrix has not been seriously injured.

There is a very common and troublesome affection popularly known as growing nail. Its most usual seat is by the side of the great toe. It does not in reality arise from any alteration of the nail, but from the adjacent soft parts being constantly pressed by the shoes, and from the perspiration of that part. These parts become swollen and inflamed; suppuration ensues, and an intensely sensitive ulcer is formed, in which the nail is imbedded. Surgical advice should at once be resorted to in these cases, as there is no probability that the ulcer will heal spontaneously. The nail should then be removed, and the inflammation permitted to move about, and thus keep up irritation. In obstinate cases it is not unfrequently necessary to
NAILS

NAIRNSHIRE 377

remove a portion of the nail, an operation attended with much pain, although quickly performed.

Nails. The making of nails by hand has been an established manufacture in the Birmingham district for 300 years. Before the successful (but very gradually) introduction of machine-made nails, men, women, and children, to the number of 60,000, were engaged in the industry. They all worked, as nailers who forge nails by hand still do, in small shops or sheds attached to their houses. In 1891, when the number employed at this work had dwindled down to 28,000, nearly one-half were females. At the village of St Ninians near Stirling in Scotland, where within the memory of persons still living 400 hands were employed in forging nails, there are now scarcely a dozen. After the introduction of slitting mills into England in 1865, which supplied nail-rods of the proper section to nail-makers, the trade became localised where it still is and gradually prospered. Iron plates are cut up into nail-rods by a pair of slitting rolls with square grooves on their surface.

In making nails by hand, the nailer heats the end of the nail-rod at his small forge, and brings it into the form of the spike of a nail by a few strokes of his hammer on the anvil. It is then cut to whatever length is wanted on a chisel, leaving it still attached to the rod. Dropping it next into open hot at the bolster, and knocking it from the rod, the nailer forms the head from the projecting end by a few more strokes of his hammer, and then the nail is finished. Dies or 'swages' are required for the heads of ornamental nails.

Nail-making machines are complicated and can hardly be understood without a number of illustrations and a lengthy description. We can only name the principal parts of one for making wrought nails from 'ridge' rolled iron plate, which, though not of very recent design, has been much used. From a strip of this sheet or plate, which has a single or double ridge along its edge, the machine cuts the nails crosswise and partially forms the head of each from the ridge at right angles to the spike. These cut pieces or blanks are next moulded to the required form between suitable dies or forming tools, and other tools come into play to shape and finish the heads. In this process the nails are formed while the iron is heated. A brief description of the machines in use at one of the largest English nail-works is given in the Engineer, 31 September 1893.

Nails are formed from strips of cold iron, the breadth of which corresponds to the length of the nail, and the fibre of which runs the long way of the nail. In cut nails the production of shank and point is done at the same time, but an additional operation is necessary if they require to be headed. The annexed diagram shows how these nails are made without waste of material.

Horseshoe-nails, which are formed of the best charcoal iron, have hitherto been the most difficult to forge, but machine-made nails even of this kind are now made, again taking the market. A very large proportion of cut nails, as well as other kinds, are now made from Bessemer and Siemens-Martin steel, and the quality of these is superior to most of the old wrought-iron nails. Cut nails are made for horticultural purposes, and for nailing laths to hold plasters. Some cast nails are annealed, and are then almost as tough as wrought nails. Cast nails are also made in brass. Wire nails, which are of French origin, are made by a machine in which the end of a reel of wire, while held for a moment by cam grippers, receives a blow from a punch to form the head. The wire is then passed through the length of a nail and two punches advance to form the point, when a 'knocker-off' throws out the finished nail.

Since 1880 nails have been successfully made in America from template scrap. This substance is sheet-iron, usually of excellent quality, and its coating of varnish lends an advantage for some, if not for most kinds of nails. Moreover, scraps of it accumulate in large quantity wherever template goods are extensively made. For one size of nail, a blank of template about 1th inch by 6th inch is crushed up or flattened edgewise into the form of a nail spike much in the same way as a fan is folded up; or the blank can be rolled up into a round nail. The machine for making these is the invention of Mr G. H. Perkins of Philadelphia, and has passed through several experimental forms. It performs the cutting, crushing, gripping, and bending operations.

Nairn Tal, the summer-resort of the lieutenant-governor of the North-west Provinces of India, nestles between spurrs of the Himalaya, beside a beautiful lake 6140 feet above sea-level, 70 miles N. of Bareilly. By a disastrous landslip here in 1880, 150 lives were lost. There is a military convalescent hospital. Pop. 5676, but over 10,000 in the season (September).

Nairn, CAROLINA OLIPHANT, BARONESS, song-writer, was born 16th August 1766, at the 'auld house' of Gask in Perthshire, the third daughter of its Jambite laird. In 1806 she married her second cousin, Major William Murray Nairne (1757-1830), who in 1824, by reversal of attainted, became the second Lord Nairne. She had three sons before one son, William (1808-37). They settled at Edinburgh, and after her husband's death she lived for three years in Ireland, then for nine on the Continent, returning at last to the new house of Gask—the old one had been pulled down in 1801. Here she died, 27th October 1845. Her eighty-seven songs appeared first under the pseudonym 'Mrs Bogan of Bogan' or 'A.R.' in The Scottish Minstrel (1821-24), and posthumously as Lays from Strathmore. Not a few of them are mere Bowlderisations of 'indelicate' favours; but four at least live, and will live, to which they are wedded—the exquisite 'Land o' the Leal' (c. 1798), 'Culler Herrin', 'The Laird o' Cockpen,' and 'The Auld House.'

See Charles Rogers' Life and Songs of Lady Nairne (1869), and T. L. Kington Oliphant's Jacobite Lairds of Gask (Grantam Club, 1870).

Nairnshire, the fourth smallest county of Scotland, is washed on the north by 10 miles by the Moray Firth, and elsewhere bounded by Elgin and Inverness shires. Till 1891 it consisted of a main body, with a maximum length of 18 miles, a mean breadth of 11, and an area of 103 sq. m., and also of five detached portions situated in Elgin, Inverness, and Ross shires, which, having a total area of 31 sq. m., were annexed to Nairnshire in 1746, but disjoined therefrom by the Boundary Commissioners in 1891. The chief rivers are the Nairn and the Findhorn, the former rising in Inverness-shire, and the latter in Caithness, flowing into the Moray Firth. The surface has a generally southward ascent from the fertile and well-wooded 'laich of Moray' near the coast, till at Carn Glass on the southern boundary it attains 102 feet. Loch Loyd (1½ by ½ mile) is the largest of seven small lakes. Less than one-tenth of the cultivated land is under crops. More attention being paid to stock than to crops. The chief antiquities are Kilravock (1400)
NAIRS

and Cawdor Castle (q.v.) at Aultbea, near Nairn, Montrose (q.v.) won his fourth victory. Nairn, Elginshire, by rail EXE, one mem-
ber; and with Inverness, &c Nairn town returns another. Pop. (1801) 8322; (1841) 9217: (1851)
Nairn, the county town, stands on the west-
bank of the river Nairn at its mouth in the Moray
Firth, the capital of Inverness-shire. The village
is a pleasant little water-place, with a small har-
bour, it was constituted a royal burgh by William the
Lion. Grant, the African traveller, was a native.
Pop. (1841) 2883: (1881) 4161: (1891) 4651.
Nairs, a Mohammedan caste in Malabar, who
have peculiar marriage customs, described under
Family (q.v.). Colonel H. Drury tells much about
the Nairs in his Reminiscences (1890).
Nala is a legendary king of ancient India, whose
love for Damayanti, the daughter of Bhima, king
of Videgarha, and the adventures arising therefrom,
forms a celebrated episode of the Mahabharata
(q.v.), as also of a separate poem, the Natledaga,
attributed to Kalidasa, as its own, that of the
Namas, the principal existing tribe of the
province, usually known under the name of Hotten-
tots (q.v.). They inhabit the region called Great
Namaqualand, north of the Gariep or Orange
River, and the country a few miles south of it,
as far as the Klaasiebergen. They are a pastoral
people of migratory habits, and live under the
rule of their chiefs.
Great Namaqualand, or Namaland, is the
extensive region in South Africa north of the
Cap Colony, extending from the Orange River to
Damarloand (q.v.) northwards, and stretching
 inland from the west coast to 29° E. long., the
 borders of British Bechuanaland. Since 1885 a
German possession, with the exception of the small
British coast territory of Walvisch Bay (q.v.), it
has an area estimated at 460,000 sq. m. It is
mainly a most sterile and barren region, and along
a coast-line of upwards of 400 miles does not pres-
ent a single running stream; but a few little bays
along the coast, such as Angra Pequena (q.v.),
Sandwich Harbour, and Walvisch Bay, afford safe
anchorages. The Rhenish Mission, which has long
been active here, has six stations in Namaland
with resident agents. There was a war between
Namaqua and Hereros (see Damarloand). Little Namaqualand is a harren dis-
cet of Cape Colony (q.v., Vol. H. p. 738), south of the
Lower Orange River. Much copper is mined
here.
Names are usually classed as either local or
personal, but neither class can be profitably studied
apart from the other; since the names of places
are frequently derived from the names of persons, while
numerous personal names prove ultimately to be
derived from local names. Thus, Washington, the
capital of the United States, derives its name from
George Washington: his father's first name in
turn was derived from that of a Durham village,
where his ancestors resided; and this village itself
obtained its name from the Wasings, a Teutonic
clan. Names must therefore not be regarded as
arbitrary signs—they have a meaning and a history,
though in many cases the meaning and the history
may be lost, and the meaning may be unascertained
with certainty.
Local names are usually either descriptive, like
Red River; personal, like Charleston; historic,
like Point Tournagain; or transferred, like New
South Wales; the name of the first person named
may be drawn between the names of physical
features, such as rivers and mountains, which are frequently
the memorials of extinct or very ancient races,
and the names of villages and hamlets, which are
usually of more recent origin, and to a large extent
derived from the names of modern nations.
Thus, in the United States, while the Red
Men have disappeared, or have been withdrawn to
remote reservations, they have left behind them
such familiar names as Niagara, Ohio, Potomac,
Mississippi, Missouri, Huron, Erie, Michigan,
Connecticut, and Massachusetts, the whole province
having bear modern names, like Brownsville,
Granston, or Madison, derived from the names of
settlers or politicians. In England also the names of
rivers are chiefly ancient and Celtic, while those
of places of habitation are mainly recent and Ten-
donic. Avon, a word which in Celtic means 'river,'
while from the Celtic word uige or wyeg, 'water,'
we derive the names of the Esk, the Usk, the Exe,
the Axe, the Ash, and the Wye; and from dube, defor,
or dur, 'water,' we have the Dove, the Dovy, and
probably the four Derwents; while tom, 'wide,'
gives us the Tame and the Thames. On the
other hand we know that Clapham was the
'home' of the Osgod Clapa, in whose house
Haracthsorn drank himself to death, while Addle-
thorpe was the place where Afulaft settled.
Many local names contain 'N' and 'S' as the home
names departed or absorbed. Thus, we find traces of Slavs
and Celts in Germany, of Romans and Celts in
Gaul, of Phoenicians on the Mediterranean coasts,
of Arabs in Sicily and Spain. Not a few names
attest the early extension of Phoenician commerce.
Such are Nair, 'the refuge;' Catania, 'the olive
harbour, in Sicily; Carthage, 'the new town:'
Carthagena in Spain is Carthago Nova or New
Carthage; Seville is the city 'on the plain:'
Malaga, 'the place for salting fish;' Tarragona
is 'the palace;' Cordova, the olive-press; and
Lisbon, 'the walled' town. Arabic names are
naturally more numerous both in Sicily and Spain.
In Sicily, besides Marsala, 'the port of Allah,'
we have several names containing the word kalat, 'a
castle,' and res, 'a cape,' such as Caltanissetta,
Cafulorgen, Calasellato, Calatalauni; together
with Rastacanzir, Rasicillo, and Rasacarmi.
In Spain numerous rivers exhibit the Arabic wordi, 'a
river' or 'valley,' in the Spanish form Gran. Such are
Guadalquivir, 'the great river;' Guadalaviar,
'the white river;' Guadalupé, 'the river of the
bay;' and many others. We find the Arabic Atlantic,
not always for that matter, in Atlantic, which is the
same name as Algiers; as well as in Almazan, 'the plain;' Almaden, 'the mine;'
Alezar, 'the palace;' Alcántara, 'the bridge.'
The province of Algarve means the 'west:'
Alcaia is 'the castle;' Kalat, 'castle,' so
common in Sicily, reappearing in the names of Cala-
trava and Calaburra. The word Modina, 'a city,'
is seen in Medinaceli and Medina Sidonia; while
Gibraltor, 'the mountain of Tarik,' preserves the
name of one of the earliest invaders.
French cities, unlike those in England, frequently
preserve the names of the Gaulish tribes of which
they were the capitals. Thus, Paris was the
capital of the Parisi, Romen of the Rotomagii,
Amiens of the Ambiani, Arras of the Atrabates,
Evreux of the Eluvovices, Beauvais of the Bellovaci,
Lisieux of the Lexovii, Chartres of the Carnutes,
Poitiers of the Pictovii, Le Mans of the Chamau-
Sens of the Senones, Saintes of the Santones,
Soissons of the Saciosii, Troyes of the Tricasses,
Lione of the Lemovices, Poitiers of the Pictenes,
Tours of the Turones, Calais of the Cadurci,
Tombe of the Tolosates, while Berri and
the other towns of the Juras are rare nowhere,
but Trévors (Trier) preserves the name of the
Treviri, Turin of the Taniri, Venice of the
Veneti, Worcester of the Huicii, Devon of the
Dannones.
The way in which the dominion of Rome was established by the foundation of colonies and privileged cities can be traced over the greater part of Europe. The names of Colonia Agrrippina, Lincoln of Lindum Colonia; Lodii was Lutum Pompeii, Pompeluna was Pompeiopolis. Fruli and Fréjus are variant corruptions of Forum Juli, Forii of Forum Livii. Jülich of Julicenum, Lillebonne of Juliolonna, Beauvais of Orbis Coloniae; Pax Augusta, Merida was Augusta Emerita, Saragossa was Cesarona Augusta. Angouleme, Aosta, Aonit, Augst, and Athis are corruptions of Augusta, Antun of Augstodunum. Klagenfurt was Claudii Forum, Flora was Forum Aurelii, and Orleans was Aurelia. We find the name of Valentia in Valenciennes, of Gratian in Grenoble, of Hadrian in Adrianople, of Constantine in Constantinople; while Constance and Contances bear the name of Constantius. Of the same class are Alexandria, Scanderbono, Antioch, and Seleucia, which recall the dominion of Alexander and his successors.

The Roman cities in Britain are commonly designated by dialectic variations of the Anglo-Saxon ceaster (a word derived from the Latin castra), which is usually appended to a fragment of the primitive Celtic name. Thus, in the Saxon region we have such names as Melton Mowbray, Dorchester, Rochester, and Colechester. In Merica we have Gloucester, Worcester, Leicester, Manchester, and Chester. In the English district we find Taunton, Leicester, Doncaster, and on the Welsh or Western side, whither we add Exeter. But many of our larger towns grew up in post-Roman times near the great fords over rivers; such are Oxford, Hereford, Hertford, Bedford, Chelmford, Guildford, Stafford, Stratford. That only the smaller streams were bridged is shown by the names of Cambridge, Tumbridge, Weybridge, and Uxbridge.

The nomenclature of Tontonic lands—Germany, England, and north-eastern France—fully bears out the description given by Tacitus of the Germans, "Nulla Germanorum populis urbes habebatur, nulla notam ex omnibus, sed Jacobus, gen. Jacobatos, tam in campo quam in silvis aedificavit. Colunt discreti ac diversi, ut fons, ut campus, ut menus placuit." Hence the local names in Italy and Germany differ essentially from those of Italy, France, Spain, Wales, and Ireland in one important respect. The first element is frequently the name of the ancient settlement who settled and remained at home in field or forest. Round these isolated dwellings villages grew up, and became known as the ton, ham, thorpe, or by of the first settler and his family. Thus, to take a few village-names from a small district in Yorkshire, we find that a man named Askot settled at Assby and another at Haisthorpe, Anlaf at Anlaby, Bardolf at Barby, Dagdale at Duggleby, Fulchra at Foggathorpe, Gamal at Ganton, Lambi at Langthorpe, Molf at Millington, Rether at Raishorpe, Hirlf at Rowlston, and other names. The major part of the names of places in Tontonic territory is thus of the same origin as the names of the earliest Teutonic settlers. Thus, we find Hrudulf at Rudelsheim, Rudisleben, and Rüdelshagen; Wolfbert at Wolfershausen; Dietrich at Dietersheim, Dietershansen, and Dietersdorff; Hululf at Rappolswell; and Rathef at Rappertswell.

On the other hand, in Celtic lands—Cornwall, Wales, Ireland, Scotland, and parts of France—a more religious spirit has caused the villages more commonly to bear the name of some local hermit or evangelist, or of some patron to whom the church is dedicated. In Teutonic lands such names are rare, and, as in the case of St Albans or St Edmundsbury, St Gallen or Glarus (St Hilarus), they commonly refer to a town which has grown up under the shadow of some great monastery. In many parts of France such names are more common, as in the case of St Omer, St Denis, St Cloud, St Malo, St Pol, St Tropez, St Tibault, and of 6000 other names. In Ireland some 2700 names begin with Kil, which denoted a church, or a monastic cell. Thus Kilkieran is the church or cell of St Ciaran, Killkenny of St Canice, Kilbride of St Brigid, Kilskeer of St Scitre, Killaloe of St Laois, and Kilkes of St Canute; and the Celtic part of Scotland we have a fair number of such names, though not so many as in the Isle of Saints; such, for instance, are Kilnarmock, Kilfinan, Kilpatrick, and Kilsyth. Kirk ('church') is common in the Teutonic part of Scotland, as in Kirkend, Kirkby, and Kirkpatrick. This prefix is also found in the north of England, where we have 31 villages called Kirkby or Kirky ('church village'). In the south of England church occasionally is found as a suffix, as in Bonchurch and Whitechurch; while in Axminster, Kidderminster, Leominster, and Westminister the suffix denotes a monastic foundation. In Wales the ecclesiastical prefix is usually Llan, meaning 'an enclosure.' Thus, Llandudno is the church of St Tudno, Llanheren of St Peris, Llangollen of St Colen, Llanfair of St Mary, Llanbadarn of St Pedern, Llanhylwy of St Illyd, Llanwonnie of St Asaph, and Bangor ('the white choir'), are named from churches, whereas every English see, except the modern see of St Albans, bears a name of secular origin. A very large number of Indian towns take their names from the temple of some deity; but where there are, for instance, Kilkhampton or Kingsbourn, Kilmuir or Muir of Mauch, a goddess to whom an ancient temple was dedicated, and Callicent is Kali's fortress.

Names derived from conspicuous trees or the nature of the vegetation are everywhere common. From this root we have such English names as Acton, Aclam, and Aukland; such Celtic names as Derry, Kildare, and Darrock; while there are about 200 Slavonic places called Dubran. Those in England named from the ash, such as Ashby and Ashton, amount to nearly the same number; but there are only from the chestnut, Chesterton, Cheston, and Cheston, named from the apple, and IV from the birch. The Slavonic name of the birch (brusa) gives its name to 40 places; the lime (lipa), to upwards of 200, including Leipzig, while in England we have Lyndhurst, Linton, and a few more. We obtain Alder or alder from the alder (Alenum), thorn, Thundon, Thon; Bromley from the broom; Rusholme from the rush; and Fernham and Fairbrough from the fern. Selinus, one of the greatest of the Greek cities in Sicily, took its name from the wild parsley. There are also names from animals; for instance, we have Lochemady, Todmorden, and Foxholes. Many towns take their names from the rivers on which they stand. In England we have Exeter on the Exe, Axminster on the Axe, Oxford on the Oke, Taunton on the Tone, Maid, Lathum on the Medway, Plymouth, Dartmouth, and Falmouth on the Fal, among others. Piton and Pitney, Pitfour and Pitfour Bridge, Pitmeddie, and Pitmedon, properly Kingston-upon-Hull, has usurped the name of the river Hull. In Asia the Russian Tomsk, Tobolsk, and most of the chief towns are thus named.

The commonest suffixes in English place-names, denoting habitation or enclosure, are -ton, -ham, -worth, -stone, and -bury in the south, and -by, -thorpe, -oft, -garth, and -theale in the north. The patronymic suffix -ing, either alone, as in Woking and Barking, or combined with -ton or -ham, as in Southwark and Southwark, denotes the settlement of a family or clan. The more usual suffixes not denoting habituation are -ey, -ley, -field, -ford, and -bridge. One of the commonest English village-names is
Newton. There are 129 Newtons, 17 Newbiggins, 12 Newports, 11 Newholds, 11 Newmasons, and 10 Newcastles. Burton, which means an enclosure on a 
burrn or hill, occurs 66 times; Barton (berc-tun), a grange or enclosure for corn or barley, occurs 45 times. Hutton, an enclosure on a 
head or projecting head of a hill and plains, occurs 280 times. There are also 
77 Suttons, 57 Norms, 36 Westons, and 14 Eastons. The settlements of the Danes in Ireland are marked by the names of such important towns as Waterford, 
Wexford, Carlingford, Limerick, and Wicklow; and three out of the four Irish provinces, Leinster, Ulster, and Munster, are still in part 
denoted only the plain of Ephesus, Africa the plain of Carthage, Europe the plain of Thebes. India derives its name from the people who dwelt on the 
banks of the Indus; Switzerland from the village of Schwyz; Peru from a small stream near Panama, 
800 miles north of the present boundary; Italy from a district of Etruria, which became known to the 
Greeks; Greece from a tribe in Epirus, probably not of Greek race, who first came in contact with the 
Romans; Russia from a Finnic corruption of the Swedish name of the vikings who occupied 
Novgorod; Hungary, Bohemia, and Bavaria from a disjunctive portion of the lands that became known to the 
Scots, an invading Irish seaf; England from the Angles; France from the Franks, a 
German tribe whose chiefs founded the ruling dynasty; 
Sweden and Denmark from the Suiiones and the 
Danes; Palestine from the Philistines who occu-
pied the portion of the coast which first became 
known to the Greeks; and Portugal from Oporto, 
the first part of the modern kingdom to be con-
quered from the Moors. Spain is the land from 
which the Phoenicians obtained the skins of 
rabbits; Brazil is the land which yielded the 
teak, a valuable dye-wood; Peru, Ecuador, 
Bolivia, Chile, Patagonia, and Argentina, 
which denote 

NAMES

The black 

sea.

It's "Irish "

The name 

of Wends, 

which means "foreigners," applied by Teutonic races to non-

Teutonic tribes. We apply it to the Cymry, 

the 

Germans apply it to Italians. Cornwall, properly 

Corn-wales, is the land inhabited by the Welsh of 

the horn; Wallon and Wallachian are Teutonic 

names used to denote neighbouring races speaking 

neo-Latin dialects. Those whom we call Lapps 
call themselves Sabame. Those whom we call 

Finns call themselves Quains or Saamalaitse, 

and by the Russians are called Tschuds, which means 

foreigners. Those whom we call ourselves either Slavs, the 'speakers,' or Serbs, 

kinnavec, were called by the Germans Wends, 

which means 'foreigners' or 'strangers.' 

The map abounds with names which record recent 

discovery or settlement. The Straits of 

Magellan, Torres Strait, the Bermudas, the islands 
of Juan Fernandez and Fernando Po bear the 
names of Spanish and Portuguese explorers; Cape 

Horn, the Orange River, New Zealand, New 

Holland, the Gulf of Carpentaria, and Tasmania 
or Van Diemen's Land bear witness to the expe-
ritions of Dutch, French, and English navigators. 

Orleans, Louisiana, and St Louis to French coloni-

sation in America; Behring Strait bears the name 
of a Dane in the Russian service; while Hudsen 

Bay, Baffin Bay, Davis Strait, Cook Strait, Bass 

Strait, Vancouver Island bear the names of
English explorers. Jamestown, Charleston, Caro-
linu, Albany, New York, and Pennsylvania date from
the time of the Stuarts, while Virginia points to
England, and Georgia to a later period. In the
first syllable, is the genitive of the proper
name Bithriith, and that the second syllable is not
ton but stone, the name probably referring to a
stone house built by an early Saxon settler. So
Thonsthorne is shown by its old form to have
nothing to do with the thorn-tree, but to be the
thorp of Thoggrimr, while Westow is the 'woman's
place.' Drypool is Driptop, the muddy or dirty
pool and not the dry pool; Thixendale takes its
name from the sixteen dales which form the town-
ship; Durham is an assimilated form from Dun-
holn, and Stepney from Stron Stepney. The old
dative or locative suffixes which occur in
the early forms of so many English and German
names have been either disused or assimilated to
other usual suffixes. Thus, the locative Wellow
(Lowelu, Lieve) has become Howshall, Column
('at the summits') has now Cowlam, Chillon ('at the
springs') has become Kilham, Alcuu ('at the
oaks') is now Acklam, Fivehac ('five pools') is
Filey, and Rodlestan ('rood-stone') is now Rud-
sdon. Sometimes the English or German
name is of little use to guess at the meaning of the
name from more modern forms; it is only when
the ancient form of the name has been recorded
that the meaning can be ascertained with certainty.

Personal names as a rule are less obscure in their
original sense. Their elements, owing to their
tendency to transference and migration, are
more liable to degradation and mutilation.
Thus, John, Ginn, Hans, and Ivan are derived from
Joannes; Sandy and Abe from Alexander; Jim,
Jago, James, and Hamish from Jacob; Benno,
Seppi, Eino, and Jole from Joseph; Peggy,
Gretchen, Maggie, and Madge from Margarett.
The origin of most of our names now in common
use is either Semitic, Greek, Latin, Teutonic, or
Celtic. To these five classes we may therefore
draw our principal types.

The old Semitic names were frequently com-
ounded with the names of deities, as is seen in
the names of Babylonian and Assyrian monarchs.
The name of Nebuchadnezzar is a prayer, 'Nebo
defend the crown;' Nebushashmon means 'Nebo
save me;' Merodach-baladan is 'Marduk gave a
son;' Abednego means 'the servant of Nebo;' Mordecai
is 'belonging to Marduk;' Shalmaneser, 'Shalman
is favourable.' The names of the
Assyrian kings, Assur-hani-pal, Assur-dan, Assur-
atis-pal, contain the name of the eponymous god
of the city of Assur, and are derived from the
same principle. Thus, Obudiah means 'the
servant of the Lord' (Jehovah); Abiel, 'the
servant of God' (Elohim); Tobias or Tobioh, 'the
Lord is good;' Abijah, 'the Lord is a father;' Abijah, 'the Lord is a brother;' Jedu, 'the Lord is
a son;' Josiah, the Spanish name, from Joseph;
Jos, 'the Lord is God;' Elijah, 'God is the Lord.'
Many Hebrew names thus compounded, such as
Elizabeth, Samuel, Daniel, Josiah, Joshua, and
John (Jehohanan, 'whom Jehovah gave; Gr.
Josthen); have become common among ourselves,
and are found together with a few, Alice, Ann,
and Thomas, which do not contain the divine
names. Modern Arabic names are derived either
from those of the Old Testament, as Yacoub, Yusuf,
Suleiman, and Ayoub (Job); or, like Ali, Hassan, Fatima, and Mohammed, from
the family of the Prophet; or from bynames of
the Prophet, like Acmhet (Ahmed), 'the praised.'

Many are compounded with multiples, like Abdul-
Kader, 'the servant of the Holy One;' or Abdul-
Raman, 'the servant of the Exalted One.'

A Greek, like a Hebrew, bore only one name,
though he might be described, for distinction, by
the name of his father or of his birthplace, as
Thoneydile of Sparta, or Aristocles, son of
Clinias. The name of the eldest son was fre-
quently the name or a variation of the name of
that of the paternal grandfather. The usage of bearing
only a single name led to the great variety of Greek
names. In the invention of which much ingenuity
was displayed. Such are Aristarchus, 'the best
governor;' Agathocles, 'good fame;' Alexander,
'the helper of men;' Philipus, 'the horse lover;
Philemon, 'the lover of thought;' Aristobulus,
'best council. Of similar construction are
Demeosthenes, Plotarch, Calliocrates, Archimedes,
Archimichus, Anaxander. There are also patre-
nymics in -ides, as Aristides and Anaxandrides.

The Romans seem at first to have borne only
one name, but at a very early period they adopted
the Sabine practice, using a prenomen or personal
name, such as Duflus, Quintus, or Marcus, followed
by a gentile or tribe name, e.g. aedilis, gens, as
Julius, Claudius, or Tullius. This, in the case of
patricians, was followed by a cognomen, usually
derived from some personal peculiarity, such as
Cesare, Cicero, Nesso, Torquatus. Thus, in
the case of Marcus Tullius Cicero, Cicero is the
prenomen, Tullius the nomen, and Cicero the
cognomen. Occasionally, in the case of distinguished
personages, an honorific cognomen, or second
cognomen, was added, such as Africannus or
Germanicus. A man might be called by the prenomen or the
cognomen, or by the two combined, e.g. Julius
Cesar, or Julius Cesar, by our modern appellation
Julius Caesar would have been contrary to
Roman usage.

The Teutonic names were compounded of
two elements, a substantive and an adjective, usually
expressing the characteristics most prized
by a fierce and warlike race. The commonest
components are born, 'bear;' wulf or wulf, 'wolf;' arm,
'sword;' heaer, 'hearth;' scild, 'shield;'
helmet, 'guard;' swast, 'stone;'
iron, 'iron'; power, 'might;' mund, 'protection;'
roth or red, 'counsel;' grim, 'fierce;' hard, 'stern;'
bold, 'bold;'
wed or weth, 'noble;' hrodd or rodd, 'glorios;
birt, 'bright. Thus, Bernard is 'the stern bear;
Arnold, 'eagle strength;' Roger, 'glorious spear;
Richard, 'stern might;' Robert, 'glorious
brightness;' Albert, 'noble brightness;' Alfred, 'noble
peace;' Athelstan, 'noble stone;' Edmund, 'noble
protection;' Ethelred, 'noble counsel.'

The Teutonic name system prevailed among the
Franks, as well as among the Goths and Lombards In
the Gothis and Lombers in Italy and Spain, as
well as in England, Germany, and Scandinavia.
Hence we get such French names as Louis
(Lothar) and Lothair (Lothair, Lateochar), with Italian
names, such as Humberto and Garibaldi, and
Spanish names, such as Gil Elías and Pedro.
In England a complete change came in with
the Norman conquest. In the early entries in
the Durham Liber Vite we find only such Anglo
names as Hereebald, Cynbert, Edwin, Arkel, and
Bemulf. In the Durham Boldon book, compiled after
the Conquest, many names, such as William,
Robert, Walter, and Ralph, are usual among
men, while the fathers of these men,
when their names are recorded, are mostly of
the old English type, such as Osbert and Turkil.
In 1380, when Bishop Hatfield made his survey of the townships of the English names had disappeared. No less than 40 per cent. of the men are named John, followed by William with 22 per cent., while, if we add Robert and Thomas, 80 per cent. of all the men's names are accounted for.

In the West Riding poll-book of 1379 John also heads the list, and more than half the men are called either William, Thomas, or Richard. In the 13th century William is the commonest name, in the 14th and following centuries John is first, with William second, till after the Revolution of 1688 William resumed, and has ever since retained the first place. This popularity of John, a name largely due to be found in the 17th century, Roger, and Richard. In the 14th century Charles, John, and George are almost unknown, and even Henry is unusual. Charles only became popular after the execution of Charles I., and George came in with the Hanoverian dynasty. In the 14th century Mary, Sarah, and Anne, now so common, are scarcely to be found, and Elizabeth usually appears in the form of Isabella. One-third of the women are named either Agnes or Alice. If to these we add Joan, Margaret, Isabella, Cecilia, and Matilda, 75 per cent. of the women are accounted for. The great vogue of names, Alice in particular, is explained by popular metrical legends. In the time of Charles I. Agnes has descended from the first place to the tenth, and Alice from the second to the sixth. Ann and Elizabeth now head the list, followed by Jane, Margaret, Mary, Alice, Isabel, Dorothy, and Ellen, in the order named, while Sarah is seventh. It may be noted that it was not till after the Restoration that two baptismal names were given to the same person.

Surnames were of very gradual introduction. In the case of Ethelred the Unready, Edmund Ironside, or Harold Godwinson, we have hereditary surnames, which were nicknames, which did not descend to the children. Hereditary surnames make their appearance in the 12th century, in the 14th they are usual rather than exceptional, and even now in the mining districts of England and in some parts of Wales they are not unusually used. It is easy to detect the process by which surnames were introduced. Thus, at the end of the 14th century we have Richard Johnson, son of John Richardson, where Johnson and Richardson are plainly descriptions or designations, but not true surnames. In the 15th century we find Johnson, Johnson. In the same century we find families whose members are designated as John Smyth, son of Thomas Wright, Agnes Smythwyf, and Alice Smythgolder. We may detect the origin of such surnames as Wood, Green, Lane, Townend, and Water, which are derived from the name of the first entry. In the 15th century John at the Wode, William by the Green, Alice in the Lane, Agnes at the Townend, Richard by the Kirkgate, Thomas atte the Welle. Other names, chiefly those of tradesmen and artisans, indicate recent migration, such as John of Doncaster, Richard of Wells, and George of Frankfort, and esquires we find territorial surnames such as John de Cawood of Cawood. In addition to these residential and territorial surnames, patronymics, such as Jones, Johnson, and Jenkins, are innumerable. There are also nicknames, such as White, Hogg, and Godfellow, which have become hereditary surnames, such as William le Mayor and Robert le Falconer; and a very large class of names of occupation. Thus, the surnames Lister, Walker, Dyer, Fuller, Tozer, Tucker, and Webster all refer to the manufacturers of buckles, Skinner, Barker, Lorimer, and Sadler to that of helmets.

The oldest Celtic names resemble the Teutonic names in their construction. Thus Dunnonrix may be translated 'the world king,' Towntorix, 'the tribe king,' Verguldefor, 'the excellent judge;' Canoblotwine, 'the war chief;' Besodica, 'the victorious.' Among the less restricted names of another description, such as Radulhr (Anglicised Rory), 'the red;' Buidhlic (Anglicised Boyd), 'the yellow;' Cumara, 'the sea-hound;' (whence MacNamara); Scolalhile, now Scully, 'the reciter;' or 'story-teller;' Bhairl, now Baird, 'the bard;' Tailbg, now Teague and Tigue, 'the poet;' and Liah, now Logie, 'the physician;' or 'leich.' With the introduction of Christianity we get names of another class, as Taggart (a corruption of sacerdos), 'the priest.' From giola (Anglicised as gillie), 'a youth;' or servant, 'we obtain Kelly, 'the servant;' Gilchrist, 'the servant of Christ;' Gillespie, 'the servant of the bishop;' Gilil, 'the servant of St. Paul;' Gilbride, 'the servant of St. Bridget;' Gilroy, 'the red-haired servant.' Mac or Mac, 'son,' which in Welsh becomes Map and Ap, has given rise to a host of patronymic surnames. Maclean is Mac-guil-in-Ean, 'the son of John;' ex Macgillainn, 'the son of the Macgillainns;' Kegan is MacEgan, Quain is MacAin (Johnson), Kow is MacHugh, Kenry and Carey are MacCiarl, Quin is MacCoom, Quirk is MacCore, Kane and Caine are MacCathnin, Cleg is MacLenn, Culey is MacCualaladh, and Macpherson means 'son of the person.'

In Wales Price and Bryce are Ap Rhys, Powell is Ap Howell, Pugh is Ap Hugh, Parry and Barry are Ap Harry, Bowen is Ap Owen, and Sevan is Ap Evan (Johnson). The Irish mr, 'grandson;' or descendent, 'which has become O, has also given rise to many surnames, but is not found in Scotland or the Isle of Man. It may be mentioned that in England any one may take another surname or as many surnames as he pleases without either an act of parliament or royal license.

The literature of the subject is very extensive, but for the most part is either obsolete or uninteresting. Three painstaking monographs, Förstenmann's Alte deutsche Namebuch, Joyce's Origin and History of Irish Names of Places, and Moore's Surnames and Place-names of the Isle of Man, may be almost unreservedly recommended. The Etymologisch-geographisches Lexicon of Dr Egi is fairly comprehensive, dealing with more than 17,000 names, and, though not invariably accurate, is a useful book of reference. Dr Taylor's Words and Places and Mr Barsby's English Surnames are less technical, and cover a wide field. Lower's Patronymics Britanniae, Cocheri's Les Noms de Lieu, Battman's Die Deutsch sprechenden Ordentlich und Wissentliches, and also Mr Blagge's Dictionary of Place-names, Miss Blagge's Dictionary of Place-names, and two books by Mr Ferguson, Surnames as a Science and the Teutonic Surname System, may also be consulted, always with caution, though valuable.

NAMUR (Flamand Neeuw), a city of Belgium, at the confluence of the Sambre with the Meuse, 35 miles by rail SE. of Brussels. With the exception of the picturesque Citadel (1784), the old fortifications have been razed since 1866, their place being taken by a cordon of seven forts. The town itself,
NANTES

has suffered so much by war that it offers little of interest—the cathedral, completed in 1772, with the grave of Don John of Austria; the Jesuit church of St Loup (1653), a large military school, an antiquarian museum, monuments of Leopold I. and the geologist Omalins d'Halloy (1783-1873), &c. Namur is noted for its cutlery, and also manufactures embroidered linen. Pop. (1872) 24,630; (1891) 30,674. Namur was captured by Louis XIV. in 1692, but recaptured in 1695, after a ten weeks' siege, by William III. and his uncle Toby.

The road from Namur, on the French frontier, lying between Hainault and Luxembourg, has an area of 1414 sq. m. Fertile and rich in minerals, it is watered by the Meuse, Sambre, and Lesse, and traversed by wooded spurs of the Ardennes (2000 feet). Pop. (1871) 313,653; (1891) 336,543.

Nanaimo, a town on the east coast of Vancouver Island, 74 miles by rail NW., of Victoria. There are large coal-mines in the district, and the town is the chief seat of this trade. Pop. (1891) 4695.

Nana Sulih, the name under which Danilu Panth, adopted son of the ex-pesishna of the Mahrrattas, became known as the leader of theBundle Mutiny in 1857, was the son of a Brahmin in the Deccan, and educated as a Hindu nobleman, he was bitterly disappointed that when the pesishna died in 1851 the latter's pension was not continued to himself; and, instead of benefiting and improving his countrymen, he made himself a pest to them, and soon was responsible for the massacres at Cawnpore (q.v., and see INDIA). After the suppression of the rebellion he escaped into Nepal.

Nancy, a beautiful French town, capital of the department of Meurthe-et-Moselle, on the Meurthe, 220 miles by rail E. of Paris and 94 W. of Strassburg. It comprises, besides several suburbs, the old and new towns, and contains many fine squares and imposing edifices. Here are statues of Stanislas Leszcynski (1677-1766), twice king of Poland, General Drouot, Thiers, and others, and among its noted institutions are the hotel-de-ville, bishop's palace, theatre, cathedral (1742), numerous churches, the 16th-century ducal palace, a university, &c. Nancy, which has grown much in importance since the German annexation of Alsace-Lorraine, has manufactures of cotton and woollen goods, artificial flowers, silks, and other products, and the local industries are embroidery on canvas and muslin. Pop. (1872) 52,955; (1886) 79,629; (1891) 87,092. Nancy, dating from the 12th century, was the capital of the duchy of Lorraine (q.v.). Here occurred the death of Charles the Bel (1477), and the birth of Callot and Claude Lorraine. See works by Cayon (1846), Lepage (1866), and Courbe (1886).

Nanda Devi. See Himalaya.

Nankeen Cloth is a very durable fabric made of a kind of cotton grown in China which is naturally of a buff-yellow colour, and this is also the colour of the cloth. The plant which yields it is a mere variety of Gossypium herbaceum. In the first half of the 19th century Nankeen cloth was much used for ladies' and children's attire, and also for men's trousers, but now the name, when applied to certain kinds of cotton goods, is not confined to fabric made from Nankeen cotton.

Nanking, capital of the province of Kiangsu, formerly the capital of China, on the Yangtsé River, 130 miles from its mouth. Its name signifies the Southern Capital. Since the removal of the capital to Peiping (q.v.) in the beginning of the 15th century, the official name has been Kiangning, though the old name is preferred popularly. From 1853 to 1864 it was the capital of the Taiping rebels, who destroyed nearly all the magnificent public buildings for which the city was once famous. Preyous to that time the walls enclosed an area nearly 20 miles in circumference, and reached in many places an elevation of 175 feet. The walls and gates of the ruined buildings were the Porcelain Tower, described under CHINA (Vol. III. p. 186; see also PAGODA, p. 604), the summer palace, and the tombs of the kings, with remarkable sepulchral statues. Since its recapture by the Chinese imperialists, in 1864, it has remained as the seat of the viceroyal government, and an arsenal has been established. In 1842 it was captured by the British. Although specified in the treaty of Tientsin (1858) as a river-port to be opened to foreign trade, little has come of this concession. Pop. 150,000.

Nansen, Fridtjof, Ph.D., a distinguished Norwegian scientist and explorer, was born at Great Fosen, Norway (near Christiania), October 10, 1861. At the age of nineteen he entered Christiania University, giving his attention there chiefly to biological investigations, in the pursuit of which, in 1882, he made a voyage in a sealing craft to the North Atlantic sealing-grounds, and, in 1883, crossed the continent of Greenland, returning in 1889. Following 1884, he matured a plan for a polar journey, a vessel (the Fram) was built, designed especially for encountering the drift-ice, and on June 24, 1893, with a crew of eleven men, he set sail from Christiania for the polar regions, the design being to reach the North Pole by letting the ship get frozen into the ice north of Siberia and drift with a current setting towards Greenland. They reached the New Siberian Islands in September, and in 1886 were in lat. 84° 4'. There, accompanied by Johansen, Nansen left the Fram in charge of his officers, and, paranoiac and pushed across the ice to Franz Josef Land, where he wintered. Here, on June 17, 1886, he met the Jackson-Harmsworth Expedition, with which he returned to Vardø, having in his cruse penetrated to lat. 86° 5', circumnavigated the Nova Zembla, Faroes, and Spitzbergen, and by this time was carried northwards and reached a point about 225 miles from the pole. One week later the Fram reached Vardø. See Nansen's Farthest North (1897), and his Life by Brogger and Røsset (1897).

Nantes, the seventh largest city of France, capital of the department of Loire-Inférieure, lies on the right bank of the Loire, 77 miles wide, and, joined by the navigable Erdre and Sèvre-Nantaise, 35 miles from the sea, and 248 by rail SW. of Paris. The natural beauties of the site have been much improved by art, and, the old town having been demolished between 1866 and 1870, Nantes is one of the handsomest cities of all France, with its noble river, quays, bridges, shady boulevards, squares, and statues. The unfinished cathedral (1484-1822) contains Colbert's splendid monument (1607) to the last Duke and Duchess of Brittany, and another (1879) to General Lamoricière. The ducal castle, founded in 985, and rebuilt in 1466, was the occasional residence of Charles VIII. and most of his successors, the prison of Cardinal de Retz and Fouquet, and the place where on 13th April 1588 Henry IV. signed the famous Edict of Nantes, which granted freedom of religion to the Huguenots (q.v.), and whose revocation by Louis XIV. on 18th October 1685 drove 400,000 French into exile. Other noteworthy buildings are the splendid church of St Nicholas (1854), the palais de justice (1863), the theatre (1877), and the National Museum (1889), with a museum, a picture-gallery, and a library of 50,000 volumes. Between 1831 and 1887 £180,000 was
expenditure on harbour-works, but the rise since 1845 of the price of coal (q.v.), near the mouth of the Lea, and the increased difficulty in the navigation of the river, have combined with depression of trade to reduce the commercial importance of Nantucket; to restore which is the object of the ship-canal (1891) between the two places. The chief exports are hardware, cereals, and preserved provisions, of which the principal are cement, Erica, canes, and wines; and their value respectively in 1872 was £2,200,000, and £2,300,000, in 1889 only £500,000 and £2,100,000. Shipbuilding also has greatly fallen off, but still is one of the leading industries, together with the preparation of sardines, and the manufacture of cement for iron, cement, and machinery, &c.; whilst 10 miles below Nantucket is the vast government steam-engine factory of Indret, employing from 2000 to 3000 hands, and familiar to every reader of Daudet's Jack.

Pop. of Nantucket (1872) 112,947; (1891) 115,600. The Portus Neposetem of the Romans, and the former capital of Brittany—a rank it disputed with Rennes—Nantes has witnessed the marriage of Anne of Brittany to Louis XII. (1499), the embarkation of the Young Pretender (1745), the 'noyades' of the execrable Carrier (q.v.), the fall of the Vendéens in 1792 (1793); and the last visit of the Duchess of Berri (1852). Fouché was a native. See works by Travers (1844) and Mellier (1872).

Nantucket, an island (15 miles long) off the south-east coast of Massachusetts. On the north shore is Nantucket town (pop. 3000), with a nearly landlocked harbour. It was formerly a great seat of whaling fishery, but is now mainly noted as a summer-resort.

Nantwich, a market-town of Cheshire, on the Weaver, 4 miles SW. of Crewe. It has some quaint old timber houses; a fine cruciform parish church, Early English to Perpendicular in style, with a central octagonal tower, 110 feet high; a Gothic town-hall (1588); a market-hall (1587); a grammar-school (1611); and Brine-hall (1858). The Haden Groes ('white salt town') of the Welsh, Nantwich was once the second largest town in Cheshire, the seat of 300 salt-works in Leland's day, a number reduced to 100 through the discovery of better brine-pits in other parts of the county. In 1628, a small distillery in the town in dudh industry has gradually quite died out. Boot and shoe making now is the principal industry. A great fire (1583), and its siege by the royalists under Lord Byron (1641) are the chief events in its history. Pop. (1851) 5241; (1861) 5753; (1891) 7412. See works by Platt (1818) and Hall (1855).

Naphtha is derived from the Persian word nafata, 'to exude,' and was originally applied to liquid hydrocarbons which exude from the ground in the neighbourhood of the Caspian Sea; in like manner it was applied to the natural oils found more or less plentifully in nearly all countries of the world, and to those obtained from the bitumen head mineral in Scotland. But the inconvenience and danger of classing all these oils indiscriminately as naphthas became apparent after the Scotch paraffin and the American petroleum refined oils began to be used for domestic illumination. This, and the somewhat still vague and vague sense, and has no specific application either scientifically or commercially to any particular liquid; but since the more general application of the words paraffin and petroleum to mineral oils the sense in which the word naphtha is used has changed. The various classes of naphtha are classified under the various British Petroleum Acts since 1862 have also aided in the interest of public safety in emphasising the wise distinction now made between the heavier and safer hydrocarbons on the one hand, and the volatile and unsafe hydrocarbon spirits or naphthas on the other.

Commercially, naphtha is now understood to apply to the inflammable distillates of crude mineral oils and coal-tar. For trade convenience the volatile distillates of petroleum and shale oil are known respectively as petroleum spirit and shale spirit, to distinguish each from the other, and both from coal-tar naphtha, which also embraces distillates of India-rubber, bones, peat, and wood, the last of these being known as wood-spirit or methyl alcohol. A few words with regard to each of these naphthas may serve to indicate more particularly the nature and method of production, and also the uses to which they are applied.

Petroleum spirit is obtained from crude petroleum in the process of refinement by distillation. The first or lightest portion of the oil which passes over from the still, being highly inflammable, is not allowed to mix with the oil, but is run into a separate or naphtha tank. American crude petroleum yields from 15 to 20 per cent. of crude naphtha, which in some of the refineries is separated into gasoline, sp. gr. 640 to 650; benzine, sp. gr. 580 to 600; and a spirit, sp. gr. 710 to 730. Russian crude petroleum yields a comparatively small proportion of naphtha, about 5 or 6 per cent., which is separated into light benzine and heavy benzine, varying in sp. gr. from 730 to 775. Shale spirit is a product of the crude oil distilled from shale, which is one of the important mining and chemical industries of Scotland. This crude oil contains 4 to 5 per cent. of naphtha, having a sp. gr. of 715 to 740; but some of the shale-oil works produce a small quantity of gasoline with a sp. gr. of 640 to 650. Coal-tar naphtha is distilled from coal tar, and is one of the most important of the man-made products of the world in the production of illuminating gas and coal-gas works. The production of tar is 10 to 12 gallons per ton of coal put through the retorts. This tar on distillation yields from 5 to 20 per cent. of naphtha according to the quality of coal used. Gas-tar from Newcastle coal gives only 5 per cent. of naphtha, while the tar from some cannel coals yields as much as 20 per cent. Coal-tar naphtha has a sp. gr. varying from 850 to 950, and is thus much heavier than the naphthas obtained from crude mineral oils. Coal-tar naphtha may be fractionated into a variety of hydrocarbons of specific gravity ranging from 132 to 350; but the two of the greatest commercial importance are benzole and ordinary naphtha. Benzole is a naphtha obtained by the destructive distillation of coal-tar or India-rubber. It also may be fractionated into a number of hydrocarbons of different densities and boiling-points. Bone-naphtha is obtained by the distillation of bones in the manufacture of animal charcoal. It is known also as bone-oil, or Dippel's animal oil. Owing to some neutral or nitrogenous substance as yet unknown, it possesses a peculiar offensive smell, and until the latest minute oil is obtained by removing this very objectionable feature bone-oil can never become of much use as a naphtha. The crude naphthas obtained from these various sources are all refined or purified by similar processes—viz. simple distillation by means of steam, as in America, and more frequently by 'coking,' in which the heavier spirits a treatment with sulphuric acid and then with caustic soda, and a subsequent washing with water are necessary previous to redistillation.

The uses to which in the industrial arts the diverse species of naphtha as applied are very numerous. The lighter spirits, such as benzole and benzine, being solvents of grease and oil, are used for detergent purposes. Benzine was for some years burned pretty generally by the poorer classes.
in cheap benzoline or sponge lamps; but its use in this way has happily been greatly restricted, if not quite superseded, by the low price at which petroleum and paraffin oils have for some years been obtainable. The light naphthas are also used for extracting the perfumes of flowers and plants, and the oil from various seeds. Gasoline is employed exclusively for carburizing gases. The bulk of the coal-tar naphtha, and much of the shale and petroleum spirit, are employed as solvents in the manufacture of india-rubber and gutta-percha goods. They are also solvents of wax, and fatty and resinous bodies generally, and are so used in many other branches of the trade. Large quantities are consumed in naphtha, torch, and other flaring lamps for outside use. They are also used as a substitute for turpentine in the preparation of paints; and in Scotland the solvent action of shale spirit is turned to account in the preparation of an anti-damp or stone- and timber-preserving fluid called Alexlinton. A considerable percentage of paraffin wax is dissolved and held in solution by the spirit; and if this liquid be applied to freestone, brick, or wood, it passes into the pores of the mate-

rial, leaving the spirit behind, so that the wax becomes permanent in the stone or wood, so that water cannot be absorbed by it. While for these various purposes all the naphthas produced in Britain find a ready market, in America and Russia petroleum spirit is made in such quantities that it has a greater share of the Western Indies market than all; and although large quantities in many petro-
llem refineries are consumed as fuel under the stills, yet much of the crude naphtha has to be burned in waste pits to get rid of it.

Naphthalene, C_{10}H_{8}, is a solid substance obtained from Coal-tar (q.v.). It forms thin, trans-
parent, brilliant plates which are quite harmless to the touch. It melts at 176° (80° C.), and boils at 422° (217° C.), but it readily sublimes at a much lower temperature. Although not very inflammable, it is used (as in the Albo-carbon light) to increase the illuminating power of coal-gas, the naphthalene being placed in a metal receiver heated by the gas-flame, and the illuminating gas passed slowly through. A smoky but brilliant light is thus obtained which under some circumstances may be useful. Naphthalene is of most importance from a scientific standpoint. Its molecule of C_{10}H_{8} may be regarded as two aromatics, benzene and naphthalene, two atoms of carbon in common; but for further information on this point, see AROMATIC SERIES.

Naphthalene forms an extensive series of derivatives in which one or more atoms of hydrogen are replaced by NO_{2}—chlorine, bromine, &c.

Napier, the chief port and city of the provincial district of Hawke's Bay, New Zealand, on the east coast of the North Island. Port Ahuriri (or Scinde Island), where most of the wholesale stores are situated, is within the municipal boundary. A railway, intended eventually to connect with Wellington, was open to Woodville (97 miles) in 1889. The deepened harbour is capable of accommodating large vessels. There is a considerable ex-
port of timber and wool, timnel and frozen meat. The value of the exports in some years greatly exceeds a million sterling (mainly wool). Pop. of Napier, which is the seat of a bishop (1891), 334.

Napier, Sir Charles, English admiral, was captured by the band of Sind and the historian of the Peninsular war, born 6th March, 1786, at Merchiston Hall, near Falkirk. At thirteen he went to sea as a naval volunteer. In 1808 he received the command of the Recruit, 18 guns, and had his thigh broken by a bullet. He kept his ship in the action in order to fire a French line-of-battle ship, and assisted in her capture. This obtained him a post-captaincy, but being thrown out of active service, he served ashore as a volunteer in the Peninsular army, and was wounded at Busaco. Commanding the Thames in 1811, he inflicted an incredible amount of damage upon the enemy in the Mediterranean. In 1814 he led the way in the hazardous ascent and descent of the Pyrenees; and he took an active part in the operations against Baltimore. In 1829 he received the command of the Galatea, a 42-gun frigate, and was employed on particular service on the coast of Portugal. Becoming acquainted with the leaders of the Constitutional party, he accepted the command of the fleet, and on the way fighting the Mignelite fleet he concluded the war, and placed Donna Maria on the throne. He was made admiral-in-chief of the Portuguese navy, and attempted to remodel it; but official and corrupt influence was too strong for him, and he returned to England. In the war between the Porte and Mehemet Ali he organised a land force, with which he stormed Sidon and defeated Ibrahim Pasha among the heights of Mount Lebanon. He took part in the naval attack on Acre, blockaded Alexandria, and in the engagement with Mehemet Ali. In 1847, now a K.C.B., he received the command of the Channel fleet. When the Russian war broke out he was sent out to command the Baltic fleet; but the capture of Bomarsund failed to realise the high expectations formed, and he was deprived of his post. He was elected for Berwick, for the parliament, for Marylebone and Southwark, and, until his death at his Hampshire seat, Merchiston Hall, November 6, 1860, helaboured to reform the naval administration. See his Life and Correspondence (1862).

Napier, Sir Charles James, the conqueror of Sind, was great-grandson of the fifth Lord Napier and a descendant of Napier of Merchiston. He was born at Westminster, 10th August 1782, and, having received a commission in his twelfth year, served in Ireland during the rebellion. He commanded the 50th Foot during the retreat on Corunna; and at the fatal battle in which Sir John Moore fell he was wounded in five places and made prisoner. Marshal Ney dismissed him, with permission to go to England, where he engaged in literary work, and even wrote an historical romance, published in 1811 by J. Murray in London. At Corujo, where he fought as a volunteer, he had two horses shot under him. At Busaco he was shot in the face, having his jaw broken and his eye injured. He recovered in time to be present at the battle of Fuentes d'Oñoro and the second siege of Badajoz. He took part in a fighting cruise off the Chesapeake, capturing American vessels, and making frequent descents upon the coasts. He did not return to Europe soon enough for Waterloo, but was engaged in the storming of Cambray, and accompanied the army to Paris. After the peace was, in 1818, made governor of the island of Cephalonia, the affairs of which he administered with great energy and intelligence; but, being of an excessively combative disposition, he became embroiled with the authorities at home. In 1838 he was made a K.C.B. He was ordered in 1841 to assume the command of the army of Bombay against the ameers of Sind. His destruction of a fortification called Emna Ghur, in 1843, was a most remarkable military feat. The fearful battle of Meecanees (q.v.), on 17th February, followed where the British, on 29th, defeated 22,000 Baluchis, strongly posted. The ameers surrendered, except Shere Mohammed, who brought 25,000 men into line of battle at Hyderabad. Napier had only 5000 men, but in three hours his little army gained a decisive victory. A few days afterwards Napier was in the palace.
of the amees, and master of Sind; and after the annexation Lord Ellenborough made him governor of Sind. He gained the respect and reverence of the inhabitants, but soon became engaged in an attempt which, instead of benefiting the Sikhs, brought upon them much suffering. In 1847 he returned to England. After attending a series of festivals in his honour, he lived in retirement until the disasters of the Sikh war caused the eyes of his countrymen to be turned to the hero of Sind. He went to India, but found on his arrival that the Sikhs had been routed. He now turned his attention, as commander-in-chief of the army in India, to the subject of military reform, and quarrelled with LordDalhousie. He made a final adieu to the East in 1851, and returned to his native country, where he resided (revived ed. 1811, 5th ed. 1828-40) at his seat, at Oaklands, near Portsmouth, on 29th August 1853. He had then attained the rank of lieutenant-general, was G.C.B., and colonel of the 22nd Foot. It must be remembered to his honour that he was the first English general who ever received in his despatches the names of private soldiers who had distinguished themselves, side by side with those of officers. Brave to rashness, ready alike with tongue, pen, and sword, quarrelsome with his superiors, but beloved by his soldiers, and, to crown all, of wild yet noble and striking appearance, was one of the most remarkable and able men of his time. See the biography by his brother (4 vols. 1837), that by W. Napier Bruce (1885), and the short Life by Sir W. Butler (1890).

His brother, Sir William Francis Patrick Napier, K.C.B., was born 17th December 1835, served in the Peninsula, and became lieutenant-general. Besides his famous History of the War in the Peninsula (6 vols. 1828-40), he published The Conquest of Scinde (1845), and the Life of his brother Sir Charles (1857). He died at Clapham, 12th February 1860. See his Life by H. A. Bruce (1864).

Napier, JOHN, Laird of Merchiston, was born at Merchiston Castle, near Edinburgh, in 1550. He matriculated at St Andrews in 1563, and travelled for some time on the Continent, returning to his native country highly informed and cultivated; but, declining all civil employments, he preferred the course of a religious life devoted to literary and scientific study. In 1593, however, he was one of a deputation of six to the king regarding the punishment of the 'Popish Rebels;' and in the same year he published his Plain Discovery (or 'Interpretation') of the whole Revelation of Saint John (1593; 5th ed. 1645). In the dedication to King James VI. he gave his majesty some very plain advice regarding the propriety of reforming his 'house, family, and court;' and the work went through numerous editions in English, Dutch, French, and German. In July 1594 he married Margaret Logan of Restalrig for the discovery of treasure in Fast Castle. About this time he seems to have devoted much of his time to the invention of warlike machines for the defence of the country against Philip of Spain, and a list of the same exists at Lambeth Palace, dated 1596. Like other eminent men of the time, Napier, though a strict Presbyterian, seems to have been a believer in astrology and divination. In 1596 he proposed the use of salt as a fertiliser of land. In 1614 he gave to the world his famous invention of logarithms (q.v.), in a treatise entitled Mirifici Logarithmorum Canonis Descriptio (4to, Edin.). Napier's next work was Rhabdologia seu Numerationis per Virgulas libri duo (Edin. 1617), detailing an invention for simplifying and shortening the processes of multiplication and division mechanics by means of the device subsequently known as Napier's Bones—an arrangement of narrow slips of bone, ivory, metal, or pastel-colored, inscribed with figures. This ingenious contrivance, however, was superseded by his logarithms. He also prepared a valuable work on logarithms, showing their mode of construction and application, and containing several propositions of spherical trigonometry, and those formulas which are now known by his name. This work was published after his death (4th April 1617) by his son Robert in 1619. There is an English translation by W. R. Macdonald, The Construction and Operation of Logarithms, with a catalogue of the various editions of Napier's works (1889). Napier's eldest son, Archibald, was raised to the peerage as the first Lord Napier by Charles I. in 1627, and his descendants still bear the title—the ninth Baron Napier having in 1872 become also Baron Etrick in the peerage of the United Kingdom.

Two Lives of Napier have been published, the one by the Earl of Buchan (1787), and the other by Mark Napier (1834), who also edited Ars Logistica, 'The Baron of Merchiston's Treatise on Logarithms' (1594; 4th ed. 1838), reprinted from a manuscript copy for the British Museum Library. This work had been originally transcribed from Napier's notes by his son Robert.

Napier, Macvey, born at Glasgow, 11th April 1776, was called to the Bar in Edinburgh, and in 1799 became a writer to the Sicilian and German Librarian (which post he retained till 1837), and in 1824 first professor of Conveyancing. He edited the supplement to the fifth edition of the Encyclopaedia Britannica (6 vols. 1816-24), and in 1829 succeeded Jeffrey as editor of the Edinburgh Review (q.v.). Among his contributors were Macaulay, Carlyle, J. S. Mill, Sir William Hamilton, and (as for the editor !) Brougham. He died 11th February 1847. See his interesting Correspondence (1870).

Napier of Magdala, Lord. Robert Cornelius Napier was born in Ceylon, 6th December 1810, and was educated at the College at Addiscombe. He entered the Bengal Engineers in 1826, served in the Sutlej campaign, was wounded while acting as chief-engineer at the siege of Multan, and had a prominent share in the battle of Goojerat. As chief-engineer of the Magdala, he received the rank of lieutenant-general. He greatly developed the resources of the country. During the Indian Mutiny he was chief-engineer in Sir Colin Campbell's army, and especially distinguished himself at the siege of Lucknow, and was made K.C.B. He received the thanks of Parliament in 1858. As commander of the expedition in Abyssinia (q.v.) in 1868, he achieved a brilliant success, both by his whole management of the short campaign and in the storming of Magdala, which ended it. On his return he received the thanks of Parliament in a connected address. He was created Baron Napier of Magdala. In 1870 he was appointed Commander-in-chief of the forces in India, and nominated a member of the Indian Council. In 1876-82 he was governor of Gibralter, and on resigning was made Field-marshal, in 1886 Constable of the Tower. He died 14th January 1890.

Naples owes its foundation to a body of Greek colonists, two settlements, Palaeopolis and Neapolis, existing for many years side by side as one community, Partenope. In 202 B.C. both were subdued by Rome; from that time Palaeopolis disappears, whilst its neighbour was made an ally of Rome. Palaeopolis was destroyed, but fell through treachery into the hands of Sulla's partisans (82 B.C.), who massacred the people. Under the empire it was a favourite place of residence for the emperors and the upper classes of Rome, and of the poets Virgil, Statius, Silius Italicus, luxury and pleasure, and its beautiful
climates, being the sources of attraction. After Rome fell, it sided with the Goths, but was seized by Belisarius (£360), and six years later by Totila. Narses recovered it soon after for the Byzantine emperors, who made it the seat of a duchy. Thus in the beginning of the 8th century asserted its independence, and retained it until the whole country was subdued by the Normans (q.v.) in the 11th. The Norman dynasty succeeded that of the Hohenstaufen. But their arch-enemies, the popes, conferred the sovereignty of Naples upon Charles of Anjou, who in the battle of Benevento (1266) annihilated the power of the imperial (Guelf) party. The predominance of the papal (Guelph) party during the reign of Robert I., who was the patron of Dante and Boccaccio, the depraved libertinism of his heiress and grand-daughter Joanna, the ravages committed by German mercenaries and by the plague, futile attempts to recover Sicily, and the feats of rival claimants to the throne, are the leading features during the rule of the Anguine dynasty, which expired with the profligate Joanna II. in 1435. It was succeeded by that of Aragon, which had ruled Sicily from the time of the Sicilian Vespers (1282). During the 14th and 15th centuries, various unsuccessful attempts were made by the House of Anjou to recover their lost sovereignty; and the country, especially near the seacoast, was repeatedly ravaged by the Turks. Between 1443 and 1514 the French and Spanish disputed between them the possession of Naples, and victory inclined to the latter. Naples was united with Sicily, forming the kingdom of the Two Sicilies, and was governed by viceroys of Spain down to 1707. The most striking episode during this period was the revolt of Masaniello (q.v.). During the war of the Spanish Succession (q.v.), Naples was wrested from Spain by Austria (1707); but in 1735 was given to Don Carlos, third son of Philip V. of Spain, who founded the Bourbon dynasty. In 1789 the troops of the French Republic invaded Naples and converted it into a Parthenopean Republic (1799). For Nelson's share in Neapolitan politics at this time, see Nelson. A second invasion by Napoleon (1806) ended in the proclamations of his brother, Joseph, as king of Naples; and, when Joseph assumed the Spanish crown in 1808, that of Naples was awarded to Josephin Murat. On the defeat and execution of Murat in 1815 the Bourbon monarch, Ferdinand IV., was restored. The insurrectionary movements of 1821 and 1848 were the forerunners of the overthrow of the Bourbon rule by Carabelli (q.v.) and the Sarдинians, and the incorporation of Naples into the kingdom of Italy (1861).

Naples (It. and Lat. Neapolis, Ital. Napoli) till 1860 the capital of the kingdom of Naples, is the largest of Italian cities, and, with the doubtful exception of Constantinople, the most beautifully situated in Europe, 161 miles by rail SE. of Rome. It is the seat of an archbishop. Pop. (1881) 463,172; (1895) 539,500. Naples is one of the busiest ports of the kingdom, exporting wine and olive-oil (£254,150), chemicals and perfumery (£285,800), live animals and animal products (£253,700), hemp and flax (§258,450), cereals (£304,700), curriery (£190,900), &c., to the annual value of £1,672,000; and importing cereals (£1,303,500), metals (£736,800), cottons (£707,250), woollens (£386,300), live animals (£354,900), earthenware, glass, &c. (£336,150), curriery (£253,250), silks (£179,500), groceries (£185,400), specie, hemp and flax, dyes, chemicals, &c., to an average total of £5,563,000. She trades principally with Britain (annual total, £2,266,400) and France (£1,861,900). Naples has many employments but few industries, and these insignificant, consisting mainly of woollen, silk, and linen manufactures, gloves, soaps, perfumery, jewellery, earthenware, hats, and carriages. Macaroni (q.v.) is almost indigenous to the Neapolitan seashore. Fishing supports many of the inhabitants. The neighbourhood is the market-garden of Italy.

Its attractiveness, due not only to its site, but to its tonic and bracing climate, specially delightful in autumn and winter, and, thanks to the sea-breeze, quite tolerable in the summer-heat, has inspired the well-known proverb, 'See Naples and then die.' Its charms have remained proof against innumerable sanitary drawbacks, defective drainage, impure water-supply, and the fever preserves of its poorer quarters with their subterranean dens, in course of removal since June 1889. The impetus to this work was given by the fearful cholera explosion of September 1884, when in one night nearly 2000 people were attacked, and about 1000 of them died. The new drainage-works carry the sewage to Cuma, thus relieving the sea-margin, under the principal hotels, of the liquid poison that used to stain the water black hard-by the most frequented marine-baths, and infect the oysters moored in baskets near the shore. An aqueduct opened in 1885 furnishes pure drinking-water to every part of the city. Along the quay considerable improvements are in progress—a new harbour, solid embankments, and commodious promenades following up the handsome squares, planted with trees and parterres, new streets cut through the more populous quarters, a fine embankment carried along the sea-front, and the Corso Vittorio Emanuele, a road traversing all the heights above the city—these latter improvements begun and partly finished under King Victor Emanuel.

Naples occupies the base and flanks of a hill-range rising, amphitheatre wise, from the sea, and divided into two unequal parts by the Capodimonte, S. Elmo, and Pizzofalcone heights, the latter ending in the small ridge crowned by the
Castell dell'Ovo. The most ancient and populous part of the city lies in the eastern crescent, and is intersected from north to south by the Via Toledo (now Via di Roma), the main historic street of Naples, more densely populated than any other of equal length. Modern buildings have lately been built on this side of the city. A fine quay extends eastward to the Castel del Carmine. To the back of this lies the poorest and most populous quarter, now being dismantled. Westward runs the less ancient city, smaller in extent, but freer space and air. Population and frequented by the more favoured classes, resident and migratory. Along the sea-margin extend the royal gardens and the Riviera di Chiaia, the lower boundary of the comparatively new quarters built against the slope. On the Vomero Hill, in the north-west, house-construction is busily going on to accommodate the inhabitants of the dismantled 'rockeries' near the harbour, for whom dwellings have also been built beyond the railway station to the east of the city. Naples is three miles long and two broad. It has a modern look, but in spite of its largely built-up portion, is full of vivacious, mercurial life so astonishing and so oppressive in its monotony to the newcomer from the north. From the precocious street Arab to the gray-haired and vociferous mendicant, with a whole army of importunate pedlars, ehammen, merchants, girls, and singers, there is no pause night or day—that 'Naples never goes to bed' is indeed a scarcely exaggerated saying! The historic interest of the suburban quarters along the shore is greater than in the city. But its poverty in Greek-Roman antiquities is made up for by its National Museum, becoming, as it were, an archaeological treasure-trove from Pompeii, while its splendid aquarium teems with typical specimens of the flora and fauna of the Mediterranean, and forms the exhibition-room of its Zoological Station. Of architectural interest Naples has but little. Besides her five forts and four gates of medieval construction, she has upwards of 300 churches, including the cathedral (1272–1316) of St Januarius (q.v.), whose blood is said to liquefy in the phials containing it on three yearly festivals. The university (1224), with nearly 100 teachers and 4150 students, is one of the richest in Italy, and, still more, the law-courts are worth visiting. Naples is excellently equipped with libraries: the National Library (1804) has 275,000 books and 8000 MSS.; the University Library (1812), 150,000 books; and the Brancacciana (1673), 150,000 books and 3000 MSS. The San Carlo Theatre (chiefly for opera) is one of the largest in Italy, though much less popular than the San Carlo, sacred to 'Pulcinella' (the Italian Punch). In fine art Naples is poor—her music, in spite of her devotion to opera, adding nothing to the European repertory; the plaintive scenes of the Mediterranean as the Venetian barcarolle are of the Adriatic. The province has an area of 336 sq. m., and a population (1889) of 1,060,032.

Napoleon I., emperor of the French. Napoleon Bonaparte, the second son of Charles Bonaparte and his wife Letizia de Ramolino, was born at Ajaccio, in Corsica, on the 15th August 1769. In 1779 he entered the Royal Military School of Brienne le Château; there he remained till the autumn of 1784, when he was transferred to the Military School of Paris, according to the usual routine. An official report on him by the Inspector of Military Schools in this year speaks highly of his conduct, and notifies his great proficiency in mathematics and fair knowledge of history and geography, but says he is not well up in ornamental studies or in Latin, and, curiously enough, adds that he will make an excellent sailor. Napoleon lost his father in 1785, and the same year he was commissioned as second-lieutenant of artillery, in which capacity he served at Valence and other garrisons. He spent his periods of leave in Corsica, and appears to have wished to remain there for life, taking part in the history of his native island, showing the first signs of that intrepid and energetic character. During the critical times following the first French Revolution, he at first joined the moderate party of Paoli; but, trying for military power, though by uniting activity and reckless audacity, issues ended in being elected lieutenant-colonel of the National Volunteers of Ajaccio, he failed in an attempt to seize that town and was obliged to return to France. Although he had forfeited his French commission by over-staying his leave, the second Revolution of 1792 was now in progress, and the new government could not spare the few trained officers whom emigration had left, and his rank was restored to him. He returned to Corsica and accompanied an expedition which unsuccessfully tried to get possession of Sardina. The French government soon called him to France to command the same arm of war, with Corsican privileges, and the islanders rallied round the patriot. Napoleon now turned against him and attempted to seize the citadel of Ajaccio for the French; but failing again, with all his relatives he fled a second time to France.

From 1794 to 1797 he is chiefly engaged in service, looked to France for his career. The narrow horizon of his native island was no longer wide enough for him, but from its bracing mountain air and from the quick blood of his race he drew a magnetic force which imparted to his decisions and actions a rapid and energy that charmed by powerful before them, while at the same time a power of calm calculation, of industry, and of self-control enabled him to employ his genius to the best advantage. The force of his personality was so overwhelming that in considering his career the regret must ever be present that the only principle that remained steadfast with him, and is the key to his conduct throughout, should have been the care for his own advancement, glory, and power. Napoleon now joined the army under Carteaux, which acted against the Marseillais who had declared against the National Convention, and invested Avignon. At this time he became attached to the younger Robespierre, who was a commissioner with the army, and embraced his Jacobin principles. He was shortly promoted Chef de Bataillon, and commanded the artillery at the siege of Toulon, where he highly distinguished himself, and is generally believed to have been the author of the plan of attack which led to the fall of the place. He was then promoted general of brigade.

On the fall of the Robespierres, Napoleon incurred serious danger, but was saved by the influence enlisted in his favour. He was, however, ordered to take command of an infantry brigade in the Army of the West. This he considered would stiffen his military career, and neglecting to obey the order, he was in consequence removed from the list of efficient general officers. Disgusted with his apparent lack of prospects, he was now anxious to be sent to Turkey to reorganise the Turkish artillery. But on the eve of the 13th Vendémiaire (5th October 1795) he was appointed second in command of the Army of the Interior at Ajaccio. His promotion was expected, having given good service next day in repelling the attack of the Sections of Paris. Influenced partly by fear and partly by appreciation of his talents, the Directory appointed General Bonaparte to the command of the Army of Italy on 23rd February 1796. On 9th March he married Josephine Tascher
de la Pagerie, widow of General Viceconte Alexandre de Beauharnais, and left Paris for Italy two days later.

On joining the army Bonaparte inaugurated a new era in the wars of the Republic. Previously the leading motives had been pure patriotism and love of liberty; Bonaparte for the first time, in his youth, had displayed a cold spirit of self-interest and plunder, which was to dominate the whole policy of France for the next twenty years. Evil as were the passions which he aroused, Napoleon's great military genius flashed forth in its full brilliancy in this his first campaign. His intellect fully comprehended the most unusual decisions, and in the untiring energy with which he carried them out, confounding his enemies by the suddenness and lightning rapidity of his blows, which never gave them time to recover. He found the French army about 39,000 strong, distributed along the eastern part of the mountainous region from Nice to Savona, and opposing 20,000 Piedmontese under Colli and 38,000 Austrians under Beaulieu. These two generals had, however, differing interests; Colli's main object was to protect Piedmont, while Beaulieu, on the other hand, expected Bonaparte could penetrate the point of junction of the two armies, it was probable they would separate in their retreat, and could be beaten singly. He therefore attacked the centre of the allied line, and, driving back the Austrians from Montenotte on the 18th, forced them to evacuate the entire position and defeated them at Millesimo the next day. Losing no time he left a division under Augereau to keep the Piedmontese in check, and led the bulk of his army against the Austrians, defeating them heavily at Dego on the 14th. The allied army disintegrated in different directions, as expected, and Bonaparte, following the Piedmontese, beat them at Ceva and Mondovi, and forced the king of Sardinia to sign the armistice of Cherasco, leaving him free to deal with the Austrians. He crossed the Po at Piacenza on the 7th May, and ordered the Austrians to retreat to the Adige. Following them he forced the bridge of Lodig on the 11th May, and entered Milan amid the rejoicings of the people on the 15th. But his ill-concealed proclamation had done its work; violence and pillage were rampant in the French army, and he could do little to prevent it. Indeed, it was an example of plundering, though under more organised forms. Heavy contributions were exacted, curiosities and works of art were demanded wholesale and despatched to France; and the Directory, demoralised by the uncustomed wealth that flowed in upon them, became as eager as Napoleon for fresh conquests and their accruing spoils. Insurrections followed at Pavia and in the Milanese, but were ruthlessly put down, and on the 27th May the army left Milan to follow Beaulieu to the Minici. The Austrians defended the whole line of this river, but Napoleon, drawing the bulk of their forces northward by a feint, broke through their centre at Borghetto, and Beaulieu retreated into Tyrol, leaving the line of the Adige to Napoleon. He at once occupied, taking Verona and Legnano, the central line of Venice, from which he frightened into submission.

The Austrians still held Mantua, which Napoleon now besieged, occupying himself at the same time in consolidating his conquests. The Austrians made strenuous efforts to save the fortress. They had about 60,000 men in Mantua, and Wurmser advanced through Tyrol with 50,000 more, while the French were only some 45,000 strong including the siege corps. Wurmser moved in three columns: one descended the Adige and threatened Verona, another moving between the Adige and the Lake of Garda drove Soubre and Massena from Rivoli and Cumna, while the third under Quasdanovich moved west of the Lake of Garda and joined Brescia, threatening the French communications. Napoleon's position was very critical, but he made a rapid decision, raised the siege of Mantua, and destroying his stores, moved all the troops he could collect against Quasdanovich, who was then at Legnago, and defeated him. Wurmser moving on Mantua found no enemy there, and missed being at the decisive point at the right time. Napoleon, leaving a small force to watch Quasdanovich, turned rapidly back against the other two Austrian columns which were not able to advance or back off. Napoleon drew off his troops at Lonato again on the 3d August and Wurmser himself at Castiglione on the 5th, driving him back into Tyrol with the loss of half his army. Mantua was again invested, but, the siege-artillery having been lost, the operations against it were rescinded to a blockade. In the beginning of September Napoleon took the offensive against Wurmser, and passing boldly behind him defeated him at Bassano, cut off his retreat, and forced him to take refuge in Mantua on the 15th September. Again, after a long siege of 30,000, but mostly recruits, advanced under Alvinzi. Napoleon could now dispose of from 38,000 to 40,000 men, having in the meantime formed the Cispadane Republic and raised an Italian legion which set free most of his garrisons. Alvinzi longed to resume the war against Napoleon's former home, and Napoleon in his turn thought of recapturing it. The Austrians under Davidovitch moved by the eastern shore of the Lake of Garda. Napoleon hastily caused the positions of Rivoli and Corona to be reoccupied to check Davidovitch, and moved himself by night from Verona down the right bank of the Adige, crossed it at Rsmooth immediately, and following the three days' battle of Arcola, during which Napoleon had a very narrow escape, but which ended in Alvinzi's defeat and retreat on Tyrol. From Arcola Napoleon dated his firm belief in his own fortune. Once again, in January 1797, Alvinzi was invited to siege Mantua. Feinting against Legnago to deceive Napoleon, he intended to make his main advance between the Adige and the lake. But Napoleon was too skilful to take decided action without full knowledge, and keeping his reserve half-way between Legnago and Mantua, he listened for certain news. When he ascertained the direction of the real attack, he moved in full force on Rivoli and won a decisive battle there on January 14, the Austrian detachment on the Lower Adige having to lay down their arms next day at Roverella. Wurmser capitulated at Mantua on the 2d February, Napoleon treating him with generosity. This first Italian campaign was perhaps the most skilful of all those of Napoleon. Everything was done accurately and rapidly, and without throwing away chances. Some of his later campaigns, though equally brilliant, show him acting more with the gambler's spirit, running unnecessary risks with almost a blind reliance upon his star, in the hope of obtaining results which should dazzle the world.

In political matters during this time Napoleon was acting less as a servant of the French Directory than as an independent ruler. He entirely ignored the instructions he received from Paris, levying contributions, entering into negotiations and depositing princes at his own will, and writing that he is not fighting for those rascals in Italy. His policy was in fact regulated in accordance with his own ambitious schemes; and we find him adopting a conciliatory attitude towards Rome with an eye to the future support of the church.

When his position in Italy was secured by
the fall of Muntaha, and by treaties with Rome and Sardinia, he prepared to advance through Carinthia and Styria on Vienna. He pushed back the Austrians into Carinthia, and advanced till he reached Leoben in Styria on the 7th April 1797. Then Austria sued for peace, and the preliminaries of Leoben were signed on the 18th April pending the conclusion of a definite peace. But further negotiations dragged on, and Austria thought that a revolution might be impending in France from which she could obtain advantage. In fact a party was rising against the Directory, consisting mainly of moderates who were eager only for a respectable government, but containing also a few royalists. Their inclusion was fatal to the party. It gave a pretext for raising the cry that the Republic was in danger, and Angereau, sent by Napoleon to Paris, sided the Directory to carry out the coup d'état of the 18th Fructidor, when the Corps Legislatif was surrounded by troops and the obnoxious representatives arrested. This strengthened the Directory for the moment, but was a step towards military despotism under Napoleon. Austria, seeing the Directory again firmly seated in power, became more eager for peace, the negotiations were hastened, and on 17th October 1797 the treaty of Campo-Formio was signed. By this treaty Belgium and the Ionian Islands, Austria also acknowledging the Cisalpine Republic, and ceding to it Lombardy, and engaging to try and get the left bank of the Rhine for France from the Germanic body. As an indemnity Austria obtained Istria, Dalmatia, and the territory of the Venetian Republic, with whom, although neutral, Napoleon had managed to pick a quarrel with this end in view.

Napoleon returned to Paris on the 6th December 1797. The Directory, fearing his ambition, thought they could only keep him quiet by employing him, and gave him command of the so-called Army of England. But he was bent on the conquest of Egypt. He appears to have had something visionary in his temperament, and to have dreamed of founding a mighty empire from the standpoint of the East, the glow and glamour of which seem always to have fascinated him. He therefore employed the resources of the Army of England to prepare for an expedition to Egypt, and the Directory yielded to his wishes, partly no doubt through the desire of getting him away from France. But their aggressive policy was at this time beset by internal difficulties. The war. The expedition sailed from Toulon on the 19th May 1798, captured Malta from the Knights of St John by treachery, and, escaping by great luck from the British fleet under Nelson, arrived at Alexandria on the 30th June. The army was disembarked in haste, for fear lest Nelson should arrive, and on the 8th July Napoleon marched on Cairo. He defeated the Mamlukes at Chebriess and the Pyramids, and entered Cairo on the 24th July. He then occupied himself with organising the government of Egypt, but his position was dèrer very hazardous by the destruction of the French fleet on the 1st August by Nelson at the battle of the Nile, and he saw that his dream of founding an empire in the East could not be realised. He thought, however, that he might create a republic and he resolved to overtake the Turkish power and march in triumph back to Europe through Asia Minor and Constantinople. He accordingly entered Syria in February 1799 with 12,000 men, but was brought to a standstill before St Jean d'Acre. Failing to capture that fortress as it was looked on as vital, he now turned north, overthrew the Turkish power and marched in triumph back to Europe through Asia Minor and Constantinople. He accordingly entered Syria in February 1799 with 12,000 men, but was brought to a standstill before St Jean d'Acre. Failing to capture that fortress as it was looked on as vital, he now turned north, overthrew the Turkish power and marched in triumph back to Europe through Asia Minor and Constantinople.
in detail as many of Melas’ troops as he could encounter. But this would not have been a sufficiently brilliant triumph, as the bulk of the Austrian army might have escaped, and trust in his success would have shaken the existence of Barray on a gambler’s cast. Leaving Masséna to be starved out, he moved to the left on Milan, and occupied the whole line of the Ticino and Po as far as Piacenza, so as to cut off entirely the retreat of the Austrians. He next advanced in the Po area, concentrating as many troops as he could spare at Stradella. The strategy was brilliant, but the risk run excessive. His army was necessarily scattered, while Melas had had time to concentrate, and he was besides ignorant of the Austrian position. He sent Desaix with a column to seek information, and moved himself on Alessandria, where he found Melas. Next day, the 14th June, Melas marched out to attack the French on the plains of Marengo, and despite all Napoleon’s efforts had actually defeated them, when fortunately Desaix returned, and his advance, together with a cavalry charge by Kellermann, changed defeat into victory. Melas, losing his head, signed a convention next day giving up almost all North Italy, though Marmont says that if he had fought another battle he must have won it. Napoleon returned to Paris with the glories of the victory, and instantly set forth for Moreau, when his liberty of action was restored to him, had won the battle of Hohenlinden on 3d December 1800. Then followed the treaty of Lunéville with Germany in February 1801, the convention with Russia in July 1801, and the treaty of Amiens with England in March 1802, when Napoleon was able to figure as the restorer of peace to the world. He then devoted himself to the reconstruction of the civil institutions of France, employing in this great work the best talent that his island furnished him, and making that profession the stamp of his own genius. The institutions thus created, which still remain for the most part, were the restored church, the judicial system, the codes, the system of local government, the university, the Bank of France, and the Legion of Honour. The spirit of the new French republic, which under republic government, was gradually veering towards monarchical, and Napoleon knew how to take advantage of events to strengthen his position, and in due time establish his own dynasty. The plot of Nivose (24th December 1800), when his life was in danger, the birth of Pauline, his union with Josephine, the arresting and transporting 130 members of the Jacobin party, with which he had long since broken; and after the conclusion of the peace of Amiens a great step was taken when, as a mark of public gratitude for the pacification of the world, he was elected First Consul for life. But though he desired the credit of making peace, so as to enable him to establish his authority over France, when that end was secured he became again eager for war, with a view to further extension of his power. He also desired to humble England, a desire that led to the repudiation of the peace of Amiens in 1803. The immediate causes of this rupture were his aggressions in Holland, in the Cisalpine Republic, in Genoa, and Piedmont, and his monstrous demand that England should supply him with a large credit for settling the peace. Thus by buying and driving all French refugees from her shores. Having thus forced England to resume hostilities, he made vast preparations for her invasion, at the same time taking the first step towards establishing his ascendency in Germany by seizing Hanover in the event of the failure followed. Napoleon preparing the way with consummate cunning. He rid himself of Moreau, his most dangerous rival, by accusing him of conspiring with the royalists, into whom he then struck terror by the execution of the Duc d’Enghien. He thus succeeded in inspiring even republicans with the conviction that the best way of preventing the inauguration of a new and despotic monarchy was to confirm his position. He chose the title of emperor as least obnoxious to the republican feeling of the army, and the change was made by a decree of the senate of the 18th May 1804.

Preparations for the invasion of England had been steadily proceeding, but Napoleon’s aggressive demeanour after becoming emperor alarmed the European cabinets, so that Pitt was able to revive the coalition, and in 1805 Napoleon found himself at war with Russia and Austria, as well as with England. Forced by England’s naval supremacy to abandon the notion of invasion, he suddenly changed front in August 1805, and led his armies through Hanover and the smaller German states, disregarding the neutrality even of Prussia herself, and reached the Danube in rear of the Austrian army under Mack, which was at Ulm. The surprise was complete; Mack surrendered on the 19th October, and Napoleon then marched on Vienna, which he entered on the 13th November. But his position was critical. The Areluchian Charles was approaching from Hungary, a Russian army was entering Moravia, and Prussia, incensed at the violation of the treaty, was inclining to the coalition. A short delay would have surrounded Napoleon with his enemies, but the Czar was impatient, and the Russian army, with a small contingent of Austrians, encountered Napoleon at Austerlitz, December 2, 1805, and was signally defeated. This caused the break-up of the coalition; the Holy Roman Empire came to an end, the Confederation of the Rhine was formed under French protection, and the Napoleonic empire was firmly established. Napoleon then entered into negotiations for peace with Russia and England, desiring to consolidate those powers at the expense of Prussia. The negotiations failed, but Prussia was mortally offended, and mobilized her army in August 1806, about which time Russia finally rejected the treaty with France. Napoleonysteryed with as much prudence as he could to carry on a stubbornly-contested campaign with Russia. An indecisive battle at Eylau was followed by a hardly-earned French victory at Friedland, 14th June 1807, and the peace of Tilsit ensued, by which Prussia lost half her territory, and had to submit to various humiliating conditions, while Russia escaped easily, and indeed got a share of the spoils.

Napoleon was now at the zenith of his power; he was the arbiter of Europe and the paramount head of a confederation of princes, among whom the masters of his own family occupied the first place. To reward his partisans he at this time created a new noblesse, and lavished upon them the public money. Full of inveterate hostility to England, Napoleon endeavoured to cripple her by the so-called Continuous System (q.v.), which all the states under his influence engaged to close their ports to English ships, and he also tried to combine all the European navies against her; but England, perceiving his aim, took the initiative and herself seized the Danish fleet. The emperor also turned his eyes to the Peninsula, where the rise of the Bourbon, the capture of Cadiz, and the intrigues of ‘the Prince of the Peace’ (see ALCUDIA) gave him an opportunity. He sent an army under Junot to Portugal, and another to Spain, which, under Murat, took Madrid. Napoleon
then procured the abdication of the king of Spain and placed his brother Joseph on the vacant throne. But he did not foresee the consequences. The spirit of reform in Austria and Portugal was inflamed, a rebellion broke out, while a British army, under Sir Arthur Wellesley, landed in Portugal, defeated Junot at Vimeira, and forced him to sign the Convention of Cintra, evacuating Portugal. So began the Peninsular war which for the future was to paralyse half Napoleon's strength, for the two sides were henceforth to fight against each other without pause.

In Germany also a spirit of revolt against his tyranny was rising, Austria at first taking the lead, and this brought on the war of 1809 against that power. Prussia, already beginning to recover her strength under the military system of Scharnhorst and von Haynau, took the lead, and the French army, which had been massed before the Danube, was forced to retire. The Austrians, after a brilliant victory at Hohenlinden, occupied Munich, and, taking advantage of the neutrality of the Emperor of Austria, undertook the capture of Vienna, the seat of the Hapsburgs. Napoleon hesitated, but was at length forced to leave his troops in the possession of the city. The Austrians, however, did not take advantage of this, and returned to the Camp of Liégnico.

Napoleon declared war on the pretext that Austria was arming, and marching through Bavaria drove the Austrians out of Ratisbon, and entered Vienna on the 13th May. Eugène Beauharnais, at the head of the Army of Italy, drove the Austrians before him into Hungary, defeated them at Raak, and joined Napoleon. The emperor then tried to cross the Danube, but was checked at Aspern and obliged to retire to the island of Lobau. Five weeks of desperate fighting followed, and the war under Hoher being carried on in Tyrol, and then Napoleon made a fresh and successful attempt to cross the Danube, and won the battle of Wagram on the 5th July. This was followed by the armistice of Zaisn and the treaty of Schönbrunn, October 20, 1809, by which he obtained a heavy indemnity in money and considerable accession of territory in Carniola, Carinthia, Croatia, and Galicia. But he mortally offended the Czar by giving a large portion of the ceded territory of Galicia to the duchy of Warsaw—i.e. to Poland.

On the 16th December 1809 Napoleon, desirous of an heir, divorced Joséphine, who was childless, and married on the 1st April 1810 the Archduchess Maria Louisa of Austria. He had no doubt the wish also to get a footing in the circle of the legitimate reigning families of Europe. A son, to whom the name of Napoleon was given, was born on March 20, 1811.

Still bent on the humiliation of England, Napoleon now tried to effect his purpose by increasing the stringency of the Continental System, but this ended in bringing him into conflict with Russia. He first approached the Tsar of Russia, Alexander I., to give him command of their seaboards, and then prohibited English trade even when carried in neutral bottoms. The Czar, already estranged by Napoleon’s alliance with Austria and his conduct as regards Poland, refused to adopt this policy, and the relations between them gradually became so strained that war was inevitable, and Napoleon took the momentous resolve to invade Russia. With Maria Louisa, he arrived at Dresden on the 16th May 1812, and was there greeted by the emperor of Austria, the king of Prussia, and other sovereigns. His army for this gigantic enterprise numbered about 600,000, including French, Germans, and Italians. He crossed the Niemen on the 24th June, reaching Vilna, which was evacuated by the Russians, on the 28th; and he remained at Vilna till the 10th July, hesitating to take the offensive, new invasion tempting him in every way.

He made overtures for peace to the Czar, who refused to treat as long as an enemy remained on Russian soil. Foiled here Napoleon at last decided to go on with his enterprise; so he advanced, and at first the Russians were in no condition to meet him, their forces being scattered. If Napoleon could have advanced rapidly to Smolensk, he might have cut the Russian forces in two, but his vast host appears to have been unmanageable. Barclay de Tolly and Bagration succeeded in uniting at Smolensk, but were driven from it on the 18th August. A resolute attack of the French army at Smolensk Napoleon again hesitated as to whether he should go into winter-quarters, but eventually decided to press on to Moscow, trusting to the moral effect of the fall of the ancient capital. It seems as if, while his superstitions belief in his star still remained, his amities and irritations had caused a deterioration in his power of rapid decision and in his energy of action. Meanwhile, great discontent had been caused in Russia by the continued retreat of the armies. Kutusov was appointed to the chief command, and stood to fight at Borodino on September 7th. Napoleon, with his back to the wall, but with an unwonted and misplaced caution refused to engage his Guard, and the victory was almost fruitless.

He entered Moscow on the 14th September, and fire broke out the next night, the first effect of which was still further to alarm the Russians, who believed it to be the work of the French. The fire raged fiercely till the 20th, and a great part of the city was burned to the ground. Had the victory of Borodino been more decisive the Czar might now have yielded; but as it was he listened to the advice of Stein and Sir R. Wilson and refused to treat with the person of the emperor. His plans were always made on the basis of immediate success, and the course to be adopted in case of failure was not considered. Again he hesitated, with the result that when at last he resolved to retire from Moscow the winter, coming earlier than usual, upset his calculations, and the miseries of that terrible retreat followed. He left Moscow on the 18th October, and, reaching the Berezina with but 12,000 men, was joined there by Oudinot and Victor, who had been holding the line of the Dvina, with 18,000. His passage of the river was opposed, but he succeeded in crossing, and on the 6th December the miserable remnant of the Grand Army reached Vilna. Macdonald, Ney, and Schwarzenberg, with 100,000 men, on the Polish frontier and in the Baltic provinces, were safe, but this was the whole available remnant of the 600,000 which he had led into Russia. It might have been expected that Napoleon would now be anxious for peace, but his haughty spirit could not brook any diminution of his prestige, and, determining to try and efface the past with fresh triumphs, he returned to Paris to raise new levies. The Czar of Russia, although he had not the means of so vast a war would be of any avail, but that he must follow up what had been begun and carry the war into Germany the next year, raising the Germans to his aid. On the 30th December 1812 the Prussian contingent of the Grand Army, under York, came over to the Russians, and on the 22d January 1813 Stein procured the meeting of the estates of East Prussia, when the Landwehr was called out. Saxony also joined Russia, contrary to the wishes of the king, but Austria and the middle states still cling to Napoleon.

Napoleon left Paris for Mainz on the 15th April 1813, his object being Dresden, which was held by the Czar and the king of Prussia. Eugène Beauharnais was on the Lower Saale with 70,000 men, and Napoleon, with 150,000 men, well officered, though raw and short of equipment, marched on him by way of Gotha. Davout was holding insurrection in north Germany with 30,000. The allies at first had only 100,000 available, the process of calling out and drilling the people being slow. Napoleon moved on Leipzig, and won the battle of Nations on the 18 May 1813, which obliged Dresden to the king of Saxony. He then followed the allies, beat them, though with heavy loss, at Bautzen on the 20th and 21st May, and forced
them to retire into Silesia. The armistice of Poischwitz, signed on the 4th of June, closed the first period of the campaign. Austria then asked for certain concessions, which if Napoleon had granted he might have checkmated the coalition of Prussia and Russia; but he seems to have been unable to bring himself to accede, and contemplated rather war with Prussia, Russia, and Austria, than peace. Conditions offered were that he should withdraw from north-west Germany, dissolve the duchy of Warsaw, and cede Illyria. These terms were very moderate, but Napoleon seems to have thought his position insecure without fresh success in war, and procrastinated. An ultimatum was delivered to him on August 8, to which he paid no attention; so on the night of the 10th to 11th August the armistice was declared at an end, and the drama swept rapidly to its crisis.

Napoleon had now 400,000 men along the Elbe frontier, while his Austrian allies were weakened by the adhesion of Austria to the coalition, as she massed her troops in Bohemia, threatening Dresden and his communications. The allies had nearly 500,000 men in three armies, the Austrian under Schwarzenberg in Bohemia, the old Prussian-Rhenish army now under Blücher, and the bulk of the Prussian force under Bernadotte in Brandenburg. The French armies were discouraged, and the allies enthusiastic; but the latter had difficulties to contend with from their heterogeneous composition and diversity of interests. The campaign opened with the battle of Jena and Auerstadt, September 14. A blow from Berlin was parried by Biliow at Grose-Beeren on August 23. Napoleon himself forced Blücher back to the Kätzchen, but had to retire again to defend Dresden from the Austrians; and his lieutenant, MacDonald, was defeated in the battle of the Kätzchen on the 28th August. Napoleon inflicted a crushing defeat on the Austrians before Dresden on the 27th, but, while preparing to cut off their retreat, was disturbed by the news of Grose-Beeren and the Kätzchen and by sudden illness, and at Kuhl lost Vandamme with 20,000 men. September was spent in repulsing the Austrians, who now entered Silesia, and towards the end of the month the allies began their converging march on their preconcerted rendezvous at Leipzig. At the same time the Confederation of the Rhine began to dissolve. The kingdom of Westphalia was upset on the 1st. October, and on the 8th Bavaria joined Austria. The Austrians were closing round Napoleon, and between the 14th and 19th October he was crushed in that battle of the Titans at Leipzig, and, brushing aside the Bavarians who tried to stop him at Hayna, on the 1st November led back the remnant of his army, some 70,000 strong, across the Rhine to Mainz.

The allies now made overtures for peace on the basis of natural frontiers, which would have left France the fruits of the first Revolution viz. Belgium and the left bank of the Rhine. Napoleon offered this, but it was rejected, and the Austrians, which Nice; but Napoleon could not be content with such entailment of his power. Evading at first the proposal, he would have accepted it, but with suspicious qualifications, when too late. The invasion of France followed. The allies issued on the 1st December, commencing a general war against Napoleon alone, and advanced with three separate armies. Schwarzenberg led the Austrians through Switzerland, Blücher crossed the Middle Rhine towards Nancy, while the northern army passed through Holland. Napoleon had yet hopes of success on account of the forces he still had in the German fortresses, the mutual distrusts of the allies, and Austria that had espoused the cause of the emperor of Austria, and the patriotism which would be aroused in France by invasion. But the allies gave him no time to utilise these influences, and Paris was not fortified. Napoleon carried on a campaign full of genius, gaining what advantage he could from the mutinies of the army. He descended into North Germany, attacked Blücher and won four battles in four days at Cambrai (February 10, 1314), Montmirail (11th), Château-Thierry (12th), and Vauchamps (13th). These successes would have enabled him to make a reasonable peace, but his personal position forbade this, and he tried subterfuge and delay.

The allies, however, were not to be trifled with, and in the beginning of March signed the treaty of Chaumont, which bound them each to keep 150,000 men on foot for twenty years. The battles of Crommelynck and Lamo followed, in which Napoleon held his sovereignty of the island of Elba, and the large fleet of March, the conferences at Chatillon came to an end, and on the 24th the allies determined to march on Paris, Marmont and Mortier, with less than 30,000 men, could make no head against him, and as soon as Napoleon learned of their approach against their communications Joseph Bonaparte withdrew Marshal Louis and the king of Rome to Tourcoing. On the 30th March the allies attacked Paris on three sides, and in the afternoon the French marshals offered to capitulate. Napoleon, when he learned the real state of affairs, hurried up in rear of the allies, but was too late, and had to fall back to Fontainebleau. His position was desperate, and to add to his difficulties Wellington, whose career of success had gradually cleared the French out of the Peninsula, had now led his victorious army across the Pyrenees into France itself.

Napoleon therefore at first offered to abdicate in favour of his son, but, when he found that would not be sufficient, he signed an unconditional abdication on the 11th April 1814. He was given the sovereignty of the island of Elba, and the title of perpetual sovereign of Elba. The papers in the person of Louis XVIII. were restored to the throne of France. But the condition of affairs was very precarious. The return of the Bourbons was most unpopular. It indeed restored the parliament, but it unsettled the position of public men and the title to estates. The army, which was preparing at the appointment to commands of emigres who had fought against France. The church began to cause alarm to the holders of national property; and by the release of prisoners and the return of the garrisons of German fortresses very large numbers of Napoleon's soldiery became dispersed over France. The coalition, too, broke up, and fresh alliances began to be sought with a view to check the aggressive spirit which Russia seemed inclined to manifest. Altogether affairs in Europe and France were in such a state as to make it not impossible that the memory of Napoleon's name would replace him in power. He accordingly resolved on making the attempt, left Elba on February 26, 1815, and landed on the French coast on the 1st March. On the 20th he entered Paris, having been joined by the leaders of the army. He was hailed as a emperor, and declared to be the saviour of France. He at once appeared as the liberator of France from the yoke put upon her by foreigners, but he could only re-establish his position in the face of the rest of Europe by war, and he was not quite the Napoleon of old, for his physical powers had declined, he had become stout, and had attacks of illness, aversion, and indolence. He had been epileptic from his youth. His mind and genius were unimpaired, and his conception of the Waterloo campaign was clear and brilliant as of yore, but the execution failed.
Europe had declared war against him, and a new coalition of four powers was formed, but only two armies were immediately ready to march, a mixed force under the Duke of Wellington in Belgium, and a Prussian army under Blücher in the Rhine provinces. The English army had its base on the sea, and the Prussian on the Rhine, so that they had converging lines of operation. Napoleon's idea was to attack only in the Rhine and, before they could concentrate, push in between them, drive them apart, and then defeat each separately. The plan was unexceptionable, resembling that of his first campaign in 1796, and the operation was successfully carried out. Napoleon left Paris on 12th June; his army being then detached between Paris and the Belgian frontier, so that the point where the blow would fall was still doubtful. On the 15th he occupied Charleroi, and was between the two allied armies, and on the 16th he defeated Blücher at Ligny before Wellington could come to his assistance. So far all had gone well with him; but now apparently his energy was not sufficient to cope rapidly with the difficulties that no doubt beset him through the shortcomings of his staff, and the spirit of mutual distrust reigned among his officers. He did nothing till the 19th, till after the battle of Ligny, it was not till 2 P.M. that he sent Grouchy with 33,000 men to follow the Prussians in the supposed direction of their retreat towards Liège, and keep them at a distance whilst he turned against Wellington. But he had lost his opportunity; the wasted hours had enabled the Prussians to dis-appear, and he did not know the fact that Blücher had taken the resolution to move on Wavre, giving up his own communications in order to reunite with Wellington. The latter had retired to a pre- viously prepared position on the Mont Mort, and had received Blücher's promise to lead his army to his assistance. So on the 18th, when Napoleon attacked the Duke, unknown to him the bulk of the Prussian army was hastening up on his right flank while Grouchy was fruitlessly engaged with the Prussian rear-guard only some few miles from the crowning gate of Waterloo, where Napoleon's forces had already finally wrecked. He fled to Paris, and abdicated for the last time on 22nd June; and, finding it impossible to escape from France, he surrendered to Captain Mailund of the Bellerophon at Rochefort on the 15th July. He was received by the British govern ment to St Helena, where he arrived on the 18th October 1815, and died there of cancer of the stomach on the 5th May 1821.

The literature referring to Napoleon may be divided into three categories: First, books dealing with his military and political career by writers contemporary with him or nearly so, such as Thiés’ Histoire du Consulat et de l’Empire; Jomini’s Vie politique et militaire de Napoléon (Eng. trans. 1855); Montholon and Gourgaud’s Monuments pour servir à l’Histoire de France sous Napoléon; and the memoirs of his generals, such as Mar mont, Masséna, and Sauret. Secondly, books touching his private life by contemporaries, such as Bonnereau’s Mémoires d’un vrai personnage; Last Case Journal of Private Life and Conversations of Napoleon at St Helena; Forsyth’s History of the Captivity of Napoleon at St Helena, from Letters and Journals of Sir Hudson Lowe; and O’Meara’s Napoleon at St. Helena. In contrast to these two, a large number of works have been written in a more critical spirit, such as those by Lainfrey, Jung, and Guillot (1859) in France, with the relevant part of Taine, and in England and America those by Seeley, O’Connor Matthew (1856), and especially by the M. Scliar (1896-97). Most valuable also is the Correspondance de Napoléon I. (32 vols.). See also articles Bonaparte, Cour Napoléon, France, Josephine, Waterloo, on the Encyclopædia Britannica (1910, 1911). Napoleon II. King of Rome and Duke of Reichstadt (1811-22), was the son of Napoleon I. and Maria Louisa (q.v.).

Napoleon III., by name Charles Louis Napoléon Bonaparte, the second emperor of the French, was born at Ajaccio, Corsica, the 20th of August, 1808. His father was Louis Bonaparte, king of Holland, brother of the first emperor, and his mother Hortense Beauharnais, Napoleon I.’s step- daughter (see Bonaparte). Louis Napoleon and his elder brothers were heirs presumptive to the imperial throne till the birth of a son to the emperor cast them into a secondary position, whence Louis Napoleon, the only survivor, was drawn in 1832, at the death of Napoleon’s only son, to become head of the House of Napoleon. That house, astoundingly risen from the netherworld of a forgotten French exile, was suddenly thrust back into private life after a complete mystery in Europe, was again raised to imperial dignity in the person of Napoleon III., only to return to obscurity in the midst of appalling disasters; and it failed to present one of the most truly tragic dramas of all time through the want of real grandeur in both Napoléons and in almost all their blood. Had the nephew been born a scion of the Bourbon house, the part of Louis-Philippe might have been his. But brought up by his mother from the year 1815, precluded by exile and imprisonment till the age of manhood from learning practical politics, he became a theorist in statecraft and a brooder on the Napoleonic legend which was his only claim to the attention of the nation. He received his early education at his mother’s residence, the castle of Balbec, on the borders of Lake Constance. Sent to the gynnsasium at Augsburg, he not only acquired there, as well as from the prolonged German surroundings of his private life, a marked German accent, but also developed those features in his individual character which were most akin to the singleness of his temperament—uncertainty and indefiniteness of thought, philosophic dreaminess laming every conviction, ambition touched with fatalism firing a morally indifferent soul.

Switzerland was the cradle of the mother of the brighter and healthier side of his nature. Had he been practical and a man of rectitude, he could have extracted from his political and social experience of that country principles sufficiently clear and wise to prove themselves the palladium of his later reign. There he developed his aptitude for military science; there, following the course of instruction given to the Swiss militia officers. Fairly competent in artillery, in engineering, in the exact sciences, in history, and in athletic exercises, he wrote and published at Zurich (1836) a Manuel d’Artillerie. He fastened with his elder brother, Louis into Italy in 1830 to assist the province of Romagna in its revolt against pontifical rule, an expedition in which Louis perished of fever, and he was himself severely stricken, but was nursed out of danger by his tender mother. This expedition, though proving that he had the disappointment of Bonapartist responsibility, was a mere episode in that Swiss period of his life, extending from 1824 to 1836, in which he was exclusively a student and a writer. When at the death of the Duke of Reichstadt he became the unconfessed head of the Bonapartists, the members of the dynasty, he sought as a pretender to learn less on any concrete historical claim to the throne of France than on the partiality of the French to a vainglorious rule, and on the intellectual interest with which he, as a man of letters, could invest the so-called Napoleonic legend. To be advanced in his stead for the hand of France and the attention of the world, interrupting twice the method of literary courtship to make personal raids upon the kingdom of Louis-Philippe. He had indeed a
fair chance. Outside of France, nationalities whose emancipation had been planned by Napoleon I., such as Ireland, Iceland, Spain (for to think of their long-deferred liberty (1831). In France he was an outlaw, because a formidable rival to legitimacy; in the struggle between the junior branch of the Bourbon dynasty and the forces at work since the Restoration he had a permanent power of intervention and might enlist, in time, the support of some of his own partisans the masses of Frenchmen who were lukewarm politicians. Moreover, Napoleon I.'s utter failure as an international politician had in no wise shaken the organisation he had given to France. The same logic with which he had parcelled out the nation; French law, French public education, French military institutions, the joint restoration of state and church stood forth as his lasting work.

Almost a stranger to France in matters of thought and tone of mind, an adventurer rather than a pre- tending, a philosopher rather than a man of action, taciturn, speculative, driven from within by a set motive rooted in a fixed idea, absorbed with German mysticism and Italian wilderness in a career so fateful to his mind that moral bridling could not avail — the philosophic socialists, in a milieu of his dreams, an idealist in some of his deeds, the heir of the French Caesar drifted to his destiny, not without some vigour and brightness, a victim to the alleged mission of his race, to which he was preserved as by hypnotic suggestion. He published in 1822-30, his Révolutions, Constitution, and Considérations politiques et Militaires sur la Suisse. In 1836, speculating on the instability of Louis-Philippe's throne, the disaffection of some of the middle classes, the general favour of his successor with the advanced parties, and the unspent prestige of Napoleon, he put his chances to a premature test by appearing among the military at Strasbourg, hoping to brige them into his service by the prospect of their remaining the paramount position which soldiers could not but see in a Napoleonic state. The rash young man was easily overpowered and conveyed to America, without being brought to trial. Being under no pledge to stay in America, Louis Napoleon returned to Europe on hearing of his mother's illness. He found her dying; two months later he received his appointment as consul of the republic; and the affair of Strasbourg had naturally enough caused many people to doubt the talent and the judgment of Louis Napoleon, still Louis-Philippe, who was politically an extremely timid monarch, dreaded some new conspiracy; the French government demanded of Switzerland the expulsion of the omnious, prince, M. Mule actually enjoying the French ambassador to demand his passports, in case of a refusal. Switzerland had neither the right nor the wish to expel, and was on the point of going to war for the distinguished refugee (who was, in fact, a Swiss citizen), when he resolved to prevent a rupture by leaving his adopted country. He now proceeded to England, and settled in London. With certain members of the British aristocracy he came to live on a footing of considerable influence, also an ambassador extraordinary. His general wander and interest to the community generally, but he impressed nobody with a belief in his future and his genius; nay, Englishmen-erred so far as to suppose that the 'silent man' was merely 'dull. In 1838 he published in London his Idees Napoleoniques, which, read in the light of subsequent events, are very significant. Europe generally regarded them as idle dreams; but in France the book went through numerous editions. In 1839 Louis Napoleon was in Scotland, and took part in the celebrated Eglinton tournament. Next year (1840) he made his second attempt on the throne of France at Boulogne. It was grotesque a failure as the one at Strasburg. Captured on the shore, while endeavouring to make his escape to the vessel that had brought him from England, Louis Napoleon was now brought to trial, and condemned to perpetual imprisonment in the fortress of Ham. Here he continued his Bonapartist propaganda by writing Aux Mains de l'Empereur, Fragments Historiques de l'Empire de la Suisse, Réponse à M. de Lamartine, Extinction du Pouvoir, &c.; and actually took part in editing the Dictionnaire de la Conversation, a valuable French encyclopedia. After an imprisonment of nine years, and the fatal experience of a first short and infatuated visit to America, he made his escape (25th May 1846), by the help of Dr Conneau, in the disguise of a workman, and gained the Belgian frontier, whence he returned to England.

The revolution of February (1848) was a victory of the working-men to whom some of his political theories were especially addressed; he hurried back to France as a virtual nominee of the Fourth Estate, or working-classes in town and country—an embarrassing position, from the obligations of which the smashing up of the Parisian Assembly was said to be a voluntary act. Louis Napoleon was released the future emperor. Being elected deputy for Paris and three other departments, he took his seat in the Constituent Assembly, 13th June 1848. On the 15th he resigned his seat and left France. Recalled in the following September by a quittance of the presidency of the provisional government, he returned to the Assembly and commenced his candidature for the presidency. The direct election of the head of the state by the people, intended as a republican institution, proved itself to be a stepping-stone to Cesarism, as Louis Napoleon's peculiar conception of himself as a moderate constitutionalist proved to be a precedent for the constitutional history of the second empire such appeals to universal suffrage bear the name of plebiscites. Out of seven and a half million of votes 5,302,834 were recorded for Prince Louis Napoleon; General Cavaignac, his genuine republican competitor, obtaining only 1,469,166.

On the 20th December he took the oath of allegiance to the Republic. For a few days concord seemed established between the different political parties in the Assembly; but the beginning of the year 1849 was marked by a reaction. Although the loss of Napoleon, still Louis-Philippe, and the tariff system of struggles between the president and his friends on the one side and the majority of the Assembly on the other—the latter being justly penetrated with the conviction that Louis Napoleon was not devoted to the interests of the Republic, but to his own. He became practically a traitor to his republican oath when, in league with monarchical Austria and the king of Naples, he put down the republican movement in Rome. Then he committed the command of the army to hands devoted to him, he established his personal supporters in posts of honour and influence, he gained by frequent visits the favour of the provincial towns, and by acts of liberality and clemency kept that of the people. He paraded as a protector of popular rights and of national prosperity, laying to the door of the Assembly the deficiencies in his government. Resolution to transform his threat into a power by personal election into a life-long one, he was hampered by the National Assembly; and, with the example of his uncle's comp d'état (18th Brumaire 1799) before him, he deliberately threw off the mask of a constitutional president, forswore his formal oath, and became a tyrant to all society. From that moment a perpetual misunderstanding, badly cloaked by material prosperity and military glory, underlay Napoleon's relation to the French and to Europe generally. His methods of government belonged to no acknowledged régime.
At the death of Morny in 1865 the soothing effect of Napoleon's measures and also his power to control the army had lasted. He marked this black day's coronation to rid himself by arms of the National Assembly, to make himself absolute ruler with the help of the military, and to muzzle all parliamentary opposition (21 December 1851). Imprisonment, banishment, deportation, the bloody repression of the journals, boldly marked this black day's work, in which the president was assisted by Morny, Maupas, and St Arnaud. France, whether wearied of the incompetent Democrats, or (as Kinglake supposes) 'cowed' by the terrible audacity of his president, appeared to acquiesce in his net; for when the vote was taken upon it on the 21st and 22nd of the same month, he was re-elected for ten years, with all the powers he demanded, by more than 7,000,000 suffrages. The imperial title was assumed exactly a year after the coup d'état, in accordance with another plebiscitary expression of the people's will.

An unlawful empire was now legally established. Men of astuteness and mediocrity took the helm of the state. The parliamentary trappings of the first empire were brought out. Resting on such a central post of army and police, Napoleon III. boasted that he was the master of all by law and order. Political parties were either denormalised or broken. He gagged the press, avered the bourgeoisie, and courted the clergy to win the peasantry. Liberals accepted him for fear of the Socialists; the Socialists applauded his plunder of the Orleans family; his old rewarled parirms among his supporters, such as Jean Finlin, made Vicomte de Persigny, chung to him as to the fount of all honour and profit; foreign monarchies accepted him as a welcome ally in the struggle against liberalism. Both his vices marrted hell on the Coup's monarchical alliance with the old royal households. He liked to profess himself the Cesar of the people, and led to the altar Eugénie de Montijo, a Spanish countess of ordinary blue blood. He endeavoured to gain international acceptance for the just, but in his mouth sophistical, doctrine as to the rights of peoples to choose their own masters, availing himself of it in the annexation of Savoy and Nice to France, in his Mexican intervention, and in his handling of the Italian question. At home he kept the people well in hand by an active economic policy. The price of bread was regulated, public works occupied and enriched the workingmen, towns, while others were undertaken to protect and enhance in value the property of the peasantry. The complete remodelling of Paris under the direction of Baron Hausmann raised considerably the value of house-property, and by the opening of a network of thoroughfares suitable for the manoeuvres of artillery and cavalry reduced to a minimum the risk arising from insurrectionary movements. The holding of international exhibitions and the signing of treaties of commerce with foreign powers were all conducive to internal peace; but the formation of unscrupulous financial, court, and clergy cliques was an ugly blot on this picture of a purely material prosperity.

To the blandishments of work and wealth at home Napoleon III. added the charm of a brilliant foreign policy. He gamed in a futile effort to stop Italy's advance to Italy; and his expedition to Mexico; the expedition to Mexico; the campaign in Lombardy against Austria, to which Napoleon was somewhat paradoxically encouraged by the murderous attack of Orsini on his person, the expeditions to Mexico and to China. In all those undertakings Napoleon enjoyed the support of the old guard. In the negotiations with Great Britain. To Prussia his relations were of a very different kind, a mixture of jealousy and patronage which boded ill for France in the event of an actual conflict.
the other players. If he fails he similarly has to pay all round. If Nap is declared and won, the stand-hand receives double all round; if lost, he only pays single. Sometimes this rule applies to four tricks when Nap receives triple and only pays single. There is no misdeal; errors in dealing require a fresh deal. A player who exposes a card before all have declared, or declares out of turn, cannot stand on that hand. A player who exposes or detaches a card after the play has begun, or who plays out of turn, is fined the value of three tricks to the stand-hand, besides what he loses if the stand-hand wins. If the stand-hand loses, the player fined receives nothing. The stand-hand is liable to no penalty for exposing or detaching a card while playing out of turn. If the stand-hand revokes he loses what he stood for. If any other player revokes, and the stand-hand wins, the revoker has to pay for all the players; if the stand-hand loses he has to pay all but the revoker, who receives nothing. Cards played after the correction of a revoke are replayed. See H. G. Playfair's Game of Napoleon (1884).

**Narbonne** (also called Belvica), a tropical African genus of myrtaceous plants, of which the one known species *N. imperialis* has showy red, white, or blue flowers, and a fruit resembling a pomegranate.

**Narbonne**, a town in the French department of Aude, on the La Robine branch of the Canal du Midi, 8 miles north-west of Mediterannean and 95 by rail E.S.E. of Toulouse. The removal since 1865 of the fortifications has been an improvement, but the place remains dirty and unattractive, with only three noteworthy buildings. These are the Romanesque cathedral of St Just (1272-1332), only the fine Gothic choir of which, 131 feet high, has been completed; and the former archbishop's palace, now the hôtel de ville, in one of whose three old towers Louis XIII. in 1642 signed the order to arrest Cinq Mars, and in which are a good museum, a library, and a picture-gallery. The white heather-honey of Narbonne maintains its ancient celebrity; the wine is chiefly used for blending purposes. Pop. (1872) 14,150; (1891) 27,056.

**Narces** is the Bourbon Martin of the Romans, their earliest colon (118 B.C.) beyond the Rhone and, situated on the high-road to Spain and the basse of the Garonne, was a place of great commercial importance. Under Tiberius it flourished greatly, its schools for a long time rivalling those of Rome. About 309 A.D. it became the capital of Gallia Narbonensis, and had its capital, forum, theatre, aqueducts, triumphal arches, &c. in 412 it was taken by the Visigoths, in 719 by the Saracens, from whom it was recovered by Pepin in 759, to fall just a century later to the arms of the Northmen. During the 11th and 12th centuries it was a prosperous manufacturing city, but subsequently it decayed. Varro and Montfalcon were natives.

**Narcissus**, according to a Greek fable, was the son of the river god Cephissus and of the nymph Liriope or Lirissa of Thebes, in Boeotia. He was a youth of extraordinary beauty, of which he was excessively vain; and for this he was punished by Nemesis by being made to fall in love with himself on seeing the reflection of his own face in a fountain. He died of this love-sickness; and on the place where he died sprung up the flower which bears his name. The story of Narcissus, narrated by Ovid, is one of comparatively late origin.

**Narcissus**, a genus of plants of the natural order Amarillidaceae, having a perianth of six showy petal-like segments, and a bell-shaped corona of various magnitude. The species are natives of the south of Europe, the north of Africa, and the temperate parts of Asia. The Common Daffodil is the only one which can be regarded as truly a native of Britain.

Many are cultivated in gardens for the sake of their beautiful and often fragrant flowers, which in general appear early in the season. Some of them are known by the names of Daffodil (q.v.) and Jonquil (q.v.). The name narcissus is popularly restricted to those which have flat (not rush-like) leaves, and a short (not bell-shaped) corona. Of these one of the best known is the Poet's Narcissus (*N. Poeticus*), with generally one-flowered scape, the flower white and fragrant, the corona with a deeply-coloured border; others with one or two flowers on the scape are in common cultivation. The Polyanthus Narcissus (*N. Tazetta*) has a number of flowers on the scape. It grows wild in stony places near the Mediterranean and eastwards to China. Many varieties of it are in cultivation. It is grown not only in gardens and greenhouses, but in water-glasses, like the hyacinth. It is very common in gardens in India, where it is highly esteemed as a flower. The narcissi in general are propagated either by seed or by offset bulbs. They succeed best in a rich light soil.

**Narcotics** (Gr. *merke; stupor*) are remedies which produce stupor if the dose be increased beyond a certain point. Opium is the most important member of the group, and the type from which most descriptions of the action of this class of medicines have been drawn; but it includes substances of various properties. Some, as alcohol, produce intoxication in lesser doses; some, as belladonna, delirium; most have a primary stimulating effect; in fact, almost every one presents some peculiarity in the way in which it affects the system, and no satisfactory general description of all its minor effects is possible. Their power of inducing sleep has procured for them the names of Hypnotics and Soporifics; while many of them are termed Anodynes, from their possessing the property of alleviating pain. Next to opium, Henbane, Indian Hemp, and Chloral may be regarded as the most important narcotics. Numerous artificially-produced organic compounds have been introduced during the last few years, some of which (e.g., paraldehyde, sulphonal as hypnotics; antipyrin, exalgin—as aniline derivative—as anodynes) will probably take a permanent place among useful remedies.

Narcotics are usually administered either with the view of inducing sleep or of alleviating pain or spasm. As, however, their action is much modified by a variety of circumstances—such as age, idiosyncrasy, and the duration of previous use—they should be administered with extreme caution, and, as a general rule, only under competent advice. The various quack medicines for children which are known as Carminatives, Soothing Syrups, &c. almost always contain some form of opium, and are a fertile cause of the great mortality which occurs in early life, especially among the poorer classes. All the narcotics when taken in excess are poisonous (see POISONS).
**NARCOTINE**

Narcotine \((\text{C}_9\text{H}_1\text{N}_2\text{O}_4)\) is one of the organic bases or alkaloids occurring in opium, in which it usually exists in the proportion of 6 or 8 per cent. It is nearly insoluble in water, but dissolves sparingly in alcohol, readily in chloroform and ether. Narcotine possesses very saline and scorching properties; its salts do not readily crystallise, and are even more bitter than those of morphine, although the substance itself is almost tasteless. When first discovered (in 1803) it was supposed to be the stimulant principle of opium; but in reality of Ammoniacal volatile oil. Its sulphate has been used in India as a substitute for quinine. Narcotine yields a great variety of compounds by decomposition, perhaps the most interesting being vanillin, the flavouring principle of vanilla.

**Nard.** See Spike-nard.

**Nardoo** \((\text{Marsilea macrophy}a)\), a plant of the order Marsileaceae (see Riccio-carps), the only plant of that order which is used in any way by man. It is found in Australia, and affords important supplies of food to the natives of some regions; it has also been of great use to American exploring parties. It grows in places occasionally covered with water; vegetating whilst moisture abounds, and then exhibiting abundance of green clover-like foliage. The leaves consisting of four leaflets at the top of a stalk some inches in length. When the water dries up, the remains of the plants are often covered with dried mud.

**Naried.** A town in the presidency of Bombay, 26 miles S.E. of Ahmedabad by rail. It does a great trade in tobacco and ghee, and has a government experimental farm. Pop. about 30,000.

**Narragansett Bay.** See Rhode Island.

**Nares**, a statesman and general, and almost the last stay of the old Roman empire in Italy, was born in Persian Armena about 475 A.D., and being a youth was probably sold as a slave in childhood. He entered the service of a household at Constantinople he rose to the post of keeper of the privy-purse to the Emperor Justinian. In 543 he was sent to India in command of a body of troops, professedly to act in concert with Belisarius (q.v.), but in reality, it is believed, with a secret commission to observe and to control that general. After some successes Nares, having disputes with Belisarius, assumed an independent authority; but his separate command was unfortunate, and he was recalled to Constantinople in 539. After some years, however, Belisarius was recalled, and Nares was appointed to the chief command in Italy. His conduct of that expedition extorted the admiration even of his enemies. Not having the command of a sufficient number of transports, he marched his army along the whole circuit of the shore of the Adriatic, and, while the enemy's ships were enabled to escape, he enabled to encounter them at Taginae (in the Apennines), where, after a desperate engagement, the Ostrogotths were totally defeated, and their king, Totila, slain. Nares took possession of Rome, and, after a series of successes both in the Peninsula and in the East, completely extinguished the Gothic power in that peninsula. Justinian appointed Nares prefect of Italy in 564. He fixed his court at Ravenna, and continued till the death of Justinian to administer the affairs of Italy with vigour and ability. But he was charged with avarice; and his exactions pressed so heavily on the exhausted resources of the population that on the death of Justinian the Romans complained to Justin of the excesses of Nares, and that emperor deprived him in 567 of his office. He is accused of thereat intriguing with Alboin, king of the Lombards, for a new invasion of Italy, and in 568 he died at Rome about 573. See Gothic, Justinian; and Hodgkin's Italy and her Invaders.

**Narthex.** See Basilica.

**Naryn**, a Russian town 101 miles WSW. of St Petersburg, on the Narva, 10 miles from its mouth in the Gulf of Finland. The navigation of the Narva was practicable by a waterfall near Simpeled at last reduced, which is taken advantage of for driving cotton-mills, sawmills, &c. Pop. 8600. Charles XII. (q.v.) won a great victory here in 1700.

**Narvaez, Ramon Maria**, general and statesman, was born at Loja, in Andalusia, 5th August 1800, and when very young served in the war of liberation against the French. In 1822, when a reactionary party took up arms to destroy the recently established government of the revolution, Narvaez ranged himself on the side of the liberals. The invasion of Spain by a French army in 1823 forced him to retire from active life until the death of Ferdinand VII. in 1832. In 1834 he maintained a hot struggle against the Carlists of the Basque Provinces, and in 1836 completely routed the Carlist leader, Gomez, near Arcos. He now became immensely popular, and was regarded as the rival of Espartero. In 1838 he cleared the district of La Mancha of brigands, and was appointed in 1840 captain-general of Old Castile. In 1843 he took an active part in the war against the Carlists; Espartero that broke out at Seville in 1840, but, that having failed, he was compelled to flee to France, where he was shortly after joined by Queen Christina (see Maria Christina), and commenced these plots against the government of Espartero which in 1845 effected its overthrow. In 1844 he was appointed president of council, and created Duke of Valencia. His ministry was thoroughly reactionary, but was overthrown in 1846. After a brief exile as special ambassador at the French court, he returned to power from 1847 to 1851, in 1856-57, again in 1858 and 1859, and, despite the efforts of O'Donnell and Prim, he retained power till his death, 23d April 1868.

**Narwhal** \((\text{Monodon})\), a genus of Cetacean, belonging to the Odontocetes or toothed whales (see Whale); it is characterised by the presence in the adult male of a long tusk, and by the early disappearance of the other structural parts of less importance. The tusks represent canine teeth, and there are sometimes a pair of them present, lying side by side in the upper jaw; there is such a specimen in the Cambridge Museum. When there is only one tusk, it is the left; rarely the female has a tusk, and rarely, however, that there are only three instances
on record. There is only one species known, *M. monodon*, which inhabits the northern seas, and has been on one or two occasions stranded on British shores; it was first recorded in Britain by Vulpius from the Isle of May in 1648; another was observed in 1890 in the Wash in Lincolnshire. It is common off the shores of Greenland, and is hunted for its oil as well as ivory; as the creature

is gregarious, sometimes travelling in herds "of many thousands," it is captured in considerable abundance. In early times the trade of the narwhal was valued in medicine, and to this day is so used by the Chinese. The ivory is very fine, and in the castle of Rosenborg at Copenhagen is a throne of the kings of Denmark made of this substance. The female narwhal is more spotted than the male, and the young darker. The fact that the female has not the tusks seems to negative the view that it is of use in spearing fish; it is no doubt used by the males for fighting—for examples are seldom unbroken. Fabricius thought that their use was to break and keep open holes in the ice during the winter, and observers have seen such breathing-holes crowded with heads of narwhal and other whales.

**Naseby**, a Northamptonshire parish, 7 miles SW. of Market-Harborough. Here, on 14th June 1645, 7,500 royalists under Charles I. and Prince Rupert were totally defeated by 14,000 parliamentarians under Fairfax and Cromwell, the king losing cannon, baggage, and 5,000 prisoners. A "blockhead obelisk," which does not mark the battlefield, was erected in 1823 on the Naseby ridge (648 feet). See Gardiner’s *History of the Great Civil War* (vol ii. 1889).

**Nash**, John, architect, born in London in 1752, after the usual course of training for his profession entered into some building speculations which enabled him to buy a small property in Car-

nathen. Here in fresh speculations he lost much money; therefore, in 1792, he returned to London and architecture, in which he speedily rose to eminence. On the strength of a patent (1797) for improvements in the construction of the arches and piers of bridges, he claimed a great part of the credit of introducing the use of metal girders. A large part of his time was occupied in designing and constructing mansion-houses for the nobility and gentry in England and Ireland, but he is chiefly celebrated in connection with the great street improvements in London. From February 1815, when he was appointed ‘architect, valuer, and agent to the Board of Woods and Forests,’ down till near the end of his professional career, he was busily engaged in the planning of routes, grouping of buildings, and fixing of sites. Regent Street and the Regent’s Park terraces are specimens of his designs. The Pavilion at Brighton, about which he published a book, was another of his works. He retired from his profession in 1834, and died May 13, 1833. Nash, notwithstanding his many defects, possessed great power of effective grouping, as is shown in his works. In the architecture of mansion-houses, the designing of ‘interiors’ was his forte.

**Nash, Richard,** better known as ‘Bean Nash,’ was born the son of an impoverished Welsh gentleman at Swansea, October 18, 1674. He was edu-

cated at Carmarthen and Jesus College, Oxford, held for some time a commission in the army, and went enterprising to Middle England. In 1704, to obtain greater attractions in the dissipations of society than the pursuits of law. He conducted the pageant at the entertainment of William III. by the Inns of Court, and is said to have declined the honour of knighthood without a pension. He made a shifty living by gambling, but in 1704 he found his true function as master of the ceremonies at Bath, where he conducted the public balls with a splendour and decency never before witnessed. In this way he came to acquire an imperial influence in the fashioning of the society of fashion. He is praised for the great care which he took of the morals of the young ladies who attended the Bath balls, always putting them on their guard against needy adventurers like himself. In his old age Beau Nash sunk into poverty, and often felt the want of that charity which he himself had never withheld. He died at Bath, February 3, 1761, and received a public funeral. A Life by Goldsmith was published anonymously in 1762.

**Nash, Thomas,** a busy writer in the last decade of Elizabeth’s reign, was born at Lowestoft in 1587, studied almost seven years at St John’s College, Cambridge, travelled abroad, visiting Italy and Germany, and married after returning to England, and the life of letters in London, and forced a shifty living from fate until the close. He kept ever a high heart amid manifold troubles, and, satirist as he was, his inexhaustible gaiety and goodness made him the darling of his friends—the ‘sweet boy’ and ‘sweet Tom’ of Greene and Francis Meres. He was dead by 1601, as prematurely as Marlowe, Peele, and Greene. Nash had a genuine relish for good literature; he praises warmly Rabelais, Ariosto, Spenser, Sidney, and Marlowe. He had also a great facility for vituperation, and the times were favourable for its exercise. His first writing was his vigorous preface to Greene’s *Menaphon* (1589), and this was quickly followed by the *Anatomie of Absurdity* (1589), a satirical discussion on social manners; a series of impetuous attacks that led to the Marprelate controversy; *Pierce Penelops*, his *Supplication to the Dice* (1592), full of keen observation and satire, and rich in autobiographical interest; *Strange News* (1593); and *Have with you to Saffron Walden* (1596), containing a vehement onslaught on Gabriel Harvey; *The Terrors of the Night*, or *A Discourse of Apparitions* (1594); *Christ’s Tears over Jeru-

salem* (1593), a long, edifying discourse; *The Un-

fortunate Traveller*, or *The Life of Jack Wilton*
(1894), the best specimen of the picturesque tale in our literature before Defoe; *The Isle of Dogs* (1739), which was at once suppressed, and is now lost, and for which the author was sent to prison; and *Lenten Staffe* (1596), *in praise of the red horn*, which was written on the death of Henry Dethum. The tragedy of *Dido* was written in collaboration with Marlowe; *Summer's Last Will and Testament*, by Nash alone.

See the Memorial Introduction in Dr Grosvart's *Complete Works of Thomas Nashe* (6 vols. 4to, Lond. 1883-84); also *A Work of John Nashe's* (1849, ed. by E. J. Lee, 1890).

Nashua, a manufacturing city of New Hampshire, is 40 miles by rail NW. of Boston, at the junction of the Merrimac and Nashua rivers. The falls of the latter, rendered available by a canal 3 miles long, supply motive-power to many manufacturing establishments, including very extensive cotton-factories and ironworks, paper and carpet mills, &c. Pop. (1850) 13,397; (1900) 23,508.

Nashville, the capital of Tennessee, is on the navigable Cumberland River, 200 miles above the Ohio, and 185 miles by rail SSW. of Louisville. The city, which is one of the principal railway centers of the U.S., is built mainly on the left bank of the river, which is crossed by a suspension bridge and a railway drawbridge to the suburb of Edgefield. Nashville is a handsome, well-built town, with an imposing state capitol of limestone ($1,500,000), a penitentiary (400 cells), and a large marine asylum. As an educational center the city is of considerable importance. The public-school system is excellent; and here are the Nashville University (1806), Vanderbilt University (Methodist Episcopal South, 1875), Central Tennessee College (for colored Methodists, 1868), Fisk University (Congregational, 1867, with a few coloured students), Roger Williams University (Baptist, also for colored students), the state normal college, &c. Most of these institutions are open to both sexes. The city has a large wholesale trade, the staples being cotton and tobacco; while its manufactures, which are rapidly extending, include cotton, flour, oil, paper, furniture, timber, leather, iron, and spirits. Founded in 1780, Nashville became the legal capital in 1834. In December 1864 the Confederates under Hood were completely defeated here by General Thomas. Pop. (1880) 43,350; (1890) 76,168; (1900) 90,865.

Naskik, a town of Bombay, on the Godavari, 31 miles S.E. of the city, 16 miles above the river station at Naskaik (4 miles distant), 100 miles NE. of Bombay. It ranks as one of the most sacred of Hindu places of pilgrimage, the banks and even the bed of the river being crowded with temples and shrines. Formerly it was a Mahratia capital; now it manufactures paper, cotton, and excellent brass and copper work. Pop. (1891) 24,429, not including 3000 at the cantonment of Decolai.—The district of Naskik has an area of 5300 sq. m., and a pop. of 643,592. See MAGIC SQUARES.

Nasmyth, James, inventor of the steam-hammer (q.v.), born in Edinburgh, Augt 10, 1802. From boyhood he evinced a turn for mechanics, and in his father's house became accustomed to use a lathe. At seventeen he constructed a steam-engine for grinding his father's colours, and made besides five models of a condensing steam-engine, and later a small road locomotive. Employed in 1829 by Maudsley, he started in business at Manchester in 1834, gained a good connection, and established at Patricroft what afterwards became known as the Bridgewater Foundry. The invention of the Steam-hammer (q.v.) was conceived in 1839, the occasion being the necessity for forging an enormous wrought-iron paddle shaft. But it did not take shape till 1842, when he found the steam-hammer as he had planned it at work at Creuzot in France. It had been invented independently in France, and Nasmyth patented his invention on his return to England, and it was adopted by the Admiralty in 1843. Business increased, and by 1856 he was able to retire with a handsome fortune, and settled at Penshurst, Kent. Amongst his other inventions was a steam-driven pill-box, and a steam crane. His son became a well-known writer on Tools and Machinery (1858), and a volume on the Moon (1874). He died in London, May 7, 1890. See Life by Smiles (1883).

Naso, See Ovid.

Nassau, formerly a Dutch duchy, now Wiesbaden, a district of the Prussian province of Hesse-Nassau (q.v.). The soil is fertile and produces some of the most esteemed Rhine wines. The chief towns are Wiesbaden (q.v.), the capital of the district; Schwalbaeh, Schlangenbad, Fachingen, Selters, and Geilnau.—The family of Nassau, the elder branch of which reigned till 1866, dates from the 10th century. The younger branch inherited the dukedom of Nassau in 1806, and as the princes of Orange took an important place in European history (see Holland). The reigning Duke of Nassau sided against Prussia in 1866, and his duchy was incorporated with Prussia (see PRUSSIA, GERMANY); and on the extinction of the main line of the Orange branch by the death of William III. of Holland, in 1890, the Duke of Nassau became Grand-duke of Luxemburg.

Nassau, the capital of New Providence, is the centre of the trade and seat of government of the Bahamas (q.v.) and a bishop's see. Pop. 5000.

Nasturtium, the botanical name properly of the Water Cress (see Cress), but also a popular designation of the Indian Cress (Tropaeolum majus). The genus Tropaeolum is the type of the small natural order Tropaeolaceae, and comprises some beautiful garden climbers, such as the widely cultivated Canary Creeper (T. aduncum), a native of Peru, and the erroneously introduced T. scopolianum, a native of Chili, which has established itself in many districts in the north of Scotland and in Wales, and garlands the walls and roofs of cottages in summer and autumn with its festoons of vivid green leaves and brilliant crimson flowers. The Indian Cress is also a native of Peru; the whole plant is characterised by a warm pungent taste and tonic stimulant, and antiscorbutic properties are ascribed to it. The flowers are employed as an ingredient in salads and for garnishing the same. The seeds when green are pickled in salt and vinegar and used as a substitute for capers. As an ornamental garden climber or creeper, the Indian Cress has been long known and admired by cottagers and others.

Natal, a British colony on the south-east coast of Africa, was discovered by Vasco da Gama on the Christmas-day (hence its name) of 1497. In the 18th century intermittent trading was carried on between the Cape Colony and Natal, which in 1800 was peopled by ninety-four distinct tribes of natives. From 1805 to 1828 the despotic Zulu chief Tyaka (Chaka) enforced his own rule and that of his own immediate tribe or family clan, the Nguni, to whom the Zulu prefix was added; from the Limpopo on the north to the Kei River in the south. Tyaka was killed in 1828 by a political faction which placed his younger brother Dingaan on the throne. Predatory Boers who had left the Cape Colony to escape British rule divided into parties and settled in the territories now known as Natal and the Transvaal; and conflicts
between Boers and natives were very frequent. In 1855 an embassy of Boers was murdered by Ding- gan, and a force of Boers proceeded to Zululand to avenge their friends. The country was at this time divided into two factions, one supporting Ding- gan, and the other his younger brother Umphande (Panda). The Boers entered into a secret treaty with Sir Garnet Wolseley, which was made known on Dinggan, who fled and was killed. Paula suc- ceeded him as king, and the Boers were recognised as lords of the soil of Natal. In December 1838 Sir George Napier, the Cape governor, had sent a detachment of Highland troops to take possession of the Natal territory on the 3rd of May following. The Boers accepted British rule and settled down in Natal, forming there, as a portion of them and their descend- ants still do, an important and loyal section of the Queen's subjects in that colony. Those of the malecontents who crossed the Drakens- berg mountains and Natal border, preferred fighting against Mosilikatze (father of Lobengula of Matabeleland) in the territory now known as the Transvaal. In 1843 Natal was officially declared to be a part of the British dominions, and the colony was formally annexed to the Cape of Good Hope on the 7th of July, 1844. At that time the natives numbered about 150,000, although in the previous century their total was nearly a million. But intertribal fights and the struggles for supremacy of Tytacker scattered the clans of Natal far and wide. Subsequent to the annexation by the crown and its administra- tion the aborigines of Natal gradually re- turned from distant places, and their numbers are now nearly half a million. In 1855 there was a great flood in the colony and Zululand, and in the following year the dreaded Zulu king, whose succession took place on the Natal northern border- line, between two sons of Umphande—viz. Cetewayo and Umbutuze. After a bloody battle on the Tugela River the forces of the former won the day and Umbutuze's beaten men took refuge in Natal. On the 14th of December, 1854, they broke open their prison, and the Zulus and their allies seized a separate British colony, and it was then given a limited form of representative institutions. Dur- ing the decade ending with 1860 considerable immigration from Great Britain took place, and the immigrants of that time and their descend- ants occupy the most of the land of the colony to-day.

In 1873 friction arose between Langalibalele, one of the chiefs on the north-west boundary, and the next magistrate. Some of the chief's young men disinherited the magistrate to give up his gong. Orders were then issued by the chief and certain of his followers. They retreated before the crown forces, but some of the Natal volunteers and mounted police cut them off in one of the mountain-passes; bloodshed ensued, and many of the Boers were killed. Langalibalele escaped to Basutoland, but was captured and brought back, tried very summarily in Maritzburg, and banished to the Cape Colony. Rigorous measures were adopted by the governor against Langalibalele's tribe and a neighbouring tribe, the home government, however, interfered and ended the injustices which had been done to the natives by the colonial authorities while under a feeling of trusteeship. Langalibalele's murder in the Cape Colony till 1885, when he was allowed to return to Natal as a prisoner on parole; he died near Maritzburg in 1889.

In 1853 there being in the colony much dissatisfaction with the methods of Downing Street rule, Sir Garnet Wolseley was succeeded by Sir Henry Bulwer. He promulgated a new constitution providing for an extension of the representative system with the check of certain eminent colonists, selected by the crown, having seats in the Legislative Council as nominee members. Sir Garnet Wolseley was suc- ceeded by Sir Bartle Frere, Her Majesty's High Commissioner for South Africa, visited the colony and came to the conclusion that in the interests of the British colonists in South Africa it was necessary to break the power of the Zulus. Despite the protest of the Natal government and Sir Henry Bulwer, the governor, an ultimatum which in itself was en- tirely illegitimate was presented on the 12th of June, 1877, to Zululand, to have the Zulus driven from the Zululand, and war ensued (see ZULUS). In this war Natal suffered severely in the lives of its young colonists, in its treasure, and in the paralysis of its trade. For several years the colony was a camp- ing-ground for British troops, for in 1881 the Transvaal Boers declared war on Natal, and Natal suffered a large number of English soldiers being sent to support these beleaguered in the Transvaal garrisons; and the fights of Schin's Hoogte, Ingogo, Lasing's Nek, and Am jaguba (see MAJUBA HILL) were all fought on British soil.

Natal is situated between 29° 10' and 31° 10' S. lat., and covers an area of 18,750 sq. m.—more than a third of that of England. Durban lies 800 miles ENE. of the Cape of Good Hope, and the colony has a seaboard on the Indian Ocean of 100 miles. It is bounded on the N. by the Tugela and Buffalo rivers, which separate British and Zulu districts: on the W. by Pondoland, and on the S. by the Umntiunana River, separating it from Pondoland. Towards the W. is the Drakensberg Mountains, and the M. by the Kwathalamba or Drakensberg Mountains, and on the S. by the Umsiuwana River, separating it from Pondoland. The mountains present a scarped and almost inaccessible face; they gradually die away, however, into the immense rolling plains of the interior. Many offshoots from these mountains traverse the colony, dividing it into a series of steps or plateaux, rising from the coast region to that of the mountains, and forming so many zones of natural productions.

The coast region, extending for 30 miles inland, is highly fertile, the climate being subtropical and healthy. In 1856 the cultivation of the sugar-cane was introduced on the coast, and as an industry it has thriven more or less ever since. Besides sup- plying all South Africa with the staple, the value of the sugar exported from the colony to England in 1894 was £75,629. The culture of the cane requiring that continuous and arduous labour which the natives did not supply, the Legislative Council had to import Indians from British India. This immigration began in 1863, and in 1891 there were 35,000 coolies in the colony with their attendant traders who followed them from India. The Assam tea-plant was introduced in 1873, and steady progress has been made with the industry, the annual yield being about 150,000 lb.; this is consumed locally, and as yet the colony still imports tea largely. Coffee and tobacco have been reared, as have also indigo, arrowroot, and ginger. All tropical fruits thrive well. The mid- land terrace is more fit for the cereals and usual European crops; while on the higher plateaux along
Natal.

Natal's chief exports are wool, sugar, ivory, and hides. The wool exported to Great Britain in 1889 was valued at £2,501,806, and the hides and skins at £2,531,383. The value of the exports was £5,033,189, but the imports were valued at £5,188,859, making the trade balance £1,055,670.

The common law in the colony is that prevailing in Holland during the 17th and 18th centuries, modified by statute law in the same way provisionally as obtains in all the South African states. The chief difference between English and Roman Dutch law rests in the laws of marriage and inheritance, but the difference is now by statute largely optional. The codes are subject to the laws regulating Europeans, as well as to special laws controlling Indian immigration. The natives are with few civilised and exempted exceptions subject in civil matters to native law, which is quite different from colonial law. The Supreme Court consists of the chief justice and two puisne justices; and there are stipendiary magistrates and administrators of native law in all important centres.

Eland (q.v.) and hartebeest (see Antelopes) are the only big game left, and these have been made royal game. There are stringent laws for the protection of deer and game-birds. Alligators are met with in a few of the central and northern rivers. Snakes, both colubrine and viperine, are in plentiful distribution throughout the colony. Many of the snakes are innocuous, and fatal bites from the poisonous species are rare. The python, which are the largest in the world, live in the seacoast forests, and in the reeds by the river-sides. The hippopotamus is still to be met with at the mouths of some of the northern rivers.

See The Annals of Natal (1889), by John Bird; Natal Almanac; Annual Blue Book; Our Colony of Natal, by Walter Morrison; The Native Question, by W. Y. Campbell; South Africa and how to reach it and Golden South Africa, by the writer of this article; South Africa, Past and Present (1877), by John Noble; Notes of a Native, by Sir John Robinson, F.R.G.S.; Brooks's Natal (1869), by the late Dr Mann; Laws and Ordinances of Natal, by Justice Cadiz; Code of Native Law, Civil and Penal, by W. Y. Campbell.

Natal, a seaport of Brazil, capital of the state of Rio Grande do Norte, stands at the mouth of the river of that name. It exports principally
cotton and sugar (nearly £200,000 annually). Pop. 10,000.

Natchez, capital of Adams county, Mississippi, is on the east bank of the Mississippi River, 214 miles by rail and about 250 by water NW. of New Orleans. It is situated on a gentle eminence looking out far over the cypress swamps of Louisiana; the part of the city along the bank, where the heavy shipping business (mainly in cotton) is transacted, is known as Natchez-under-the-Hill. The public buildings include a Roman Catholic Church and a University. It has a large hospital. Natchez, which was settled by the French in 1716, derives its name from a former tribe of Indians (see MOUND BUILDERS). Pop. (1870) 9067; (1890) 7068; (1900) 12,210.

National Covenant. See COVENANT.

National Debt. National or public debts although of early origin were relatively of small importance before the development of the modern system of banking and credit, and it is only during the present century that they have become almost universal on a considerable scale (see Gilbart on Banking, sect. 1). So long as it was necessary either to finance wars, or to meet revenue needs or assign specified revenues, it was not possible that public debts could attain any great magnitude. As soon, however, as governments were able to borrow simply on credit, national debts in the modern sense of the term grew rapidly. In less than a century after the formation of the Bank of England (1694), when for the first time in English history the item 'Interest and Management of the Public Debt' appears in the national accounts, Adam Smith felt compelled to enter a protest against 'the progress of the enormous debts which at present (1776) oppress, and will in the long run probably ruin, all the great nations of Europe.' At that time the public debts of the civilised world were, however, only about one-tenth of their present aggregate amount, which exceeds five thousand millions sterling, of which 1400 millions are due to the progress of the enormous debts which, at present (1776) oppress, and will in the long run probably ruin, all the great nations of Europe. At that time the public debts of the civilised world were, however, only about one-tenth of their present aggregate amount, which exceeds five thousand millions sterling, of which 1400 millions are due to

NATCHEZ 403

National Debt, as it is generally understood, includes all public debts, whether incurred by the state or by local corporations, whether for purposes of expenditure or of revenue. In the latter case the national debt includes the public debt of all the states. It is usually reckoned by the amount of the interest, which, however, is not a correct criterion. The usual way of reckoning the national debt is by the amount of the principal. The national debt of the United States in the year 1600 amounted to £2,500,000,000. But, apart from this natural growth, in recent years a quasi-socialistic tendency has become pronounced, which has involved a large increase in public expenditure. The full importance, however, of this element can only be seen when account is taken of local taxation and indebtedness, which would require a separate investigation. It must also be observed that money spent on debts incurred for public purposes may in some cases—e.g. railways, docks, &c.—be directly profitable, and in others—e.g. education, be indirectly remunerative.

The nature of public debts differs in some respects from that of private obligations. It is held, for example, that the principle of surety is involved in the assumption of public debts, the state or corporation having the discretionary power of enforcing the claims of its subjects for payment of the national (as contrasted with domestic) obligations of another state. The interests of bondholders may in consequence give rise to diplomatic intervention and thus lead to political disturbance. As in some cases, France has the discretionary power of enforcing the claims of its subjects for payment of the national (as contrasted with domestic) obligations of another state. The interests of bondholders may in consequence give rise to diplomatic intervention and thus lead to political disturbance. As in some cases, France has

It has been maintained that if a debt has been incurred in order to raise revenue, it is not equitable to require that if the government has only received the capital sum borrowed in this form—it is only equitably bound to pay back the principal with an allowance for its depreciation. This position was taken up by some writers as regards the English debt incurred during the period of the bank restriction, when Bank of England notes were inconvertible and depreciated, and more recently the same reasoning was advanced in the United States after the civil war. The obvious answer, however, is that a government would receive so much less capital if the lendings were made, which has been shown recently by the action of England and France in Egypt and Tunis respectively. The growth of national indebtedness has, however, hitherto been generally accompanied by an increased sense of responsibility founded on the importance of public credit, and fundamental revolutions in government have not generally given rise to repudiation, although the new government might strongly disapprove of the objects for which the debt was incurred, or the methods by which the money was raised—compare, for example, the revolutions in the United States during the present century and the recent revolution in Brazil. On several occasions, however, specious arguments for partial repudiation have been urged and met with some popular countenance.

simply to a return of the original sum actually advanced. The practical conclusion to be drawn from this argument is that in general it is bad policy for a nation to borrow at a discount, because it lends itself to conversion to a lower rate of interest. Suppose, for example, that a nation can only borrow at par at six per cent., it is better to do this than to borrow nominally at three per cent., and create (roughly) double the amount of capital obligation for the same sum to actually be needed. In the former case every fall in the rate of interest at which the nation can borrow may be taken advantage of by a process of conversion, whilst in the latter case the whole gain accrues to the fundholders. It is of course assumed that the debt may be paid off at any time (other nations, &c.) and the payment is not definitely fixed for certain dates. The opposite case of the United States shows the importance of this provision.

It is, however, true as before that the certainty of a high interest for a fixed period will operate upon the government by many hundreds, and the point is that the state is better fitted to take advantage of the probable ultimate fall in the rate of interest. A somewhat similar argument has been advanced by Dr Chalmers and others to show that, considering the nature of a state's income, it is far more advantageous to take advantage of the potentially lower rates of interest, however extraordinary, out of present taxation, rather than to resort to loans. The contention is that to meet the actual expenditure the government must in some form or other actually take the required amount from the sum total of the national wealth. If it makes a loan it is said that it really takes the capital amount and diverts it from productive purposes, just as effectually as if it obtained the money directly by taxation, but in addition is burdened in perpetuity with the interest. The circumstances under which the national debt of England was so largely increased in the Napoleonic wars no doubt seemed to justify this position. According to a Parliamentary Return of 1869 it was shown that from 1783-1816 the total income raised from taxes amounted to 1,119 millions, and the total expenditure, except for the interest on the national debt, was 2,363 millions. That is, if the government, say, for the twenty-three years (apart from the interest on the debt) the whole civil, military, and naval expenditure was less than the amount received in taxes by 46 millions. Now the charge on the original debt before the war was about 35 millions per annum, or for the twenty-three years about 220 millions. Against this must be set the 46 millions of surplus shown above, leaving on the net deficit for the twenty-three years about 174 millions. But to meet this sum the national debt was by a process of borrowing and repayment actually increased by some 502 millions (see Noble's National Finance, p. 3, note). In answer to the general argument, however, it may be pointed out that the borrowing may be made not from the productive resources of a country, but from foreign capital or the general accumulations of the world, or that the loan may absorb wealth which otherwise would not have been saved at all, or may intercept wealth which might otherwise have gone abroad. Mill argues (Political Economy, bk. v. chap. vii. sect. i.) that a sufficient test whether the loan is really made from productive capital is given by the rate of interest. If the interest rate of the loans rises the presumption is that the productive capital has been really drawn upon. This test, however, can only be used with caution, if at all, for the rate of interest depends upon many factors—e.g. the state of credit, the general economic conditions, the conditions on which the payment of the war debt is based, and on the precipitation of the outbreak of war a rise is certain to take place independently of the action upon the productive capital of the country.

The question next arises: Supposing a national debt in some cases should, and in others be held as a mortgage to extinguish the principal? The chief arguments against any special exertion towards repayment are the following: (1) It is said that the payment of the interest constitutes a mere transfer of wealth from one class of the community to another, and that therefore it is no real burden. But in reply it may be urged that all taxation necessarily implies loss both directly and indirectly, the indirect and 'unseen' loss being much greater. Thus in the United Kingdom, whilst the direct expense of the customs duties has been placed at only 34 per cent., the indirect customs duty is about 40 per cent., and others at from 20 to 30 per cent. In some cases also the national creditors are foreigners, and in this case the payment of interest must take the form of a real exportation of wealth without any corresponding importation. (2) It is argued that with the natural progress of society industrial countries become more and more wealthy, that the burden of the debt becomes proportionately less, and that its extinction can be more easily effected at a more remote period. It ought to be observed, however, that the rapid accumulations of the past few years have apparently had a beneficial effect on the national expenditure, and that there are many beneficial uses to which surplus capital can be applied. (3) It is said that the rate of interest tends to fall, and that therefore by conversion the real burden may become less and less. The recent experience of the United Kingdom and of the United States tends to support this view; but, on the other hand, there are various elements of uncertainty—e.g. the opening war of the new countries, the possibility of great wars, &c. (4) It is maintained that the existence of a national debt, which consists practically of perpetual annuities guaranteed by the state, is a national convenience; and further, that if the debt were extinguished, capital would tend to be sent abroad. The power is the condi-

NATIONAL DEBT
case of exceptional need. A nation already overburdened with debt might be obliged, in the case of a great war, immediately to resort to a forced currency, which would be liable to a serious or fluctuating depreciation. An issue of irredeemable notes is generally the worst method of incurring a national obligation, being in reality a species of forced loan. Some years ago a favourite argument against the immediate repayment of public debts was the assertion that there was in progress a natural depreciation of gold, owing to the great discoveries and to the use of credit substitutes. This argument must, however, now be reversed, for there can be little doubt that since 1875 the tendency has been towards an appreciation of gold. Such an appreciation of the standard in which most debts have been contracted—in other words, a general fall in prices—makes the real burden of these debts so much heavier. With low prices, including low money incomes, the same amount of nominal taxation involves greater sacrifices on the part of the taxpayers. Accordingly, if the standard is likely to appreciate still further (see Bimetallism) and no remedy is adopted, it will be advisable to reduce money debts of all kinds as rapidly as possible. It should also be noticed that an old tax is no tax, and that in a period of perishable tax receipts, the incidence of all taxes which must afterwards be reimposed. It is preferable to create a surplus for the extinction of debt. The case of the United States with a surplus larger than can be made use of, and raised to a great extent by burdensome indirect taxation, may be regarded rather as an exception which proves the rule.

In conclusion, attention may be called to the principal methods adopted for the extinction of public debts. These are mainly two, with variations in detail. First, there is the simple plan of raising directly more in revenue than is required for expenditure, and devoting the surplus directly to the purchase of the bonds or stock representing the debt. A continuous surplus of this kind is a real sinking fund. In former times many fallacies have been drawn from the fact of success in a sinking fund. Financiers have been deluded through spurious figures on the powers of indefinite accumulation of a small sum at compound interest, and have imagined that if a certain sum were set aside and allowed to grow in this manner, it would inensibly absorb any debt. In the meantime, the state, as in the case of England during the Napoleonic wars, continues to borrow at higher rates, a sinking fund of this kind is directly worse than useless, although indirectly it may find defenders on the ground that a suspension would injure the national credit. The second method of repayment which has met with much favour in the United Kingdom is the substitution of terminable annuities, at a higher rate, for the perpetual annuities which constitute the interest on the debt. The great advantage of this plan is that there is so far no apparent surplus which the government or the people can devote to a reduction of taxes or to new modes of expenditure, whilst a sinking fund is always open to attack. If the stock has originally been issued at a discount, and at a time when the assumption of the annuity gives the nation the benefit of this rise, whilst the gradual diminution of the debt itself increases the tendency to rise. A third method of getting rid of public debts has sometimes been proposed, founded upon the fact that a state can lower the rate of interest without that it is better than is the case of private individuals or companies. Thus it is argued that the state might purchase the railways, the ordinary stock of which in the United Kingdom earns about four per cent., with money borrowed at less than three per cent. Adam Smith, however, long ago pointed out that a nation can rarely make a profit of any industrial undertaking, and to judge by recent experience, governments are likely to pay far more than the real market value of any stock they may purchase.

DEBT OF UNITED KINGDOM AT VARIOUS DATES.

At the Revolution of 1688 .................. £264,283
At the accession of Queen Anne .......... 167,744,494
At the accession of George I ............... 167,375,409
At the end of the Spanish war .......... 176,211,622
At the Peace of Paris, 1783 ............... 152,716,049
At the end of the American war, 1784 .. 243,608,145
At the Peace of Amiens, 1802 ....... 262,376,858
At commencement of Crimean war, 1854 . 760,682,649
In 1880 ................................ 680,944,026

The debt in 1880 was divided into unredeemed funded debt, £580,359,562; estimated capital of terminable annuities, £71,731,869; and unfunded debt (i.e. debt which the state is not bound to repay), £32,252,305 (including outstanding bonds for purchase-money of Suez Canal shares). In 1795–97 took place the first great consolidation of various stocks (see CONSOLS; in 1883 the 3 per cent. were exchanged into new stock to bear 21/2 per cent. till 1908, and thereafter 21% (or EXCHEQUER BILLS). In 1897 the total debt—£644,969,847—was £55,000,000 less than the gross annual value of property and profits assessed for income-tax.

DEBT OF UNITED STATES.

In 1791 .................. $75,403,470 In 1861 .......... $160,580,872 In 1812 .................. 42,709,277 In 1862 .......... 124,110,412 In 1821 .................. 24,922,328 In 1863 .......... 1,107,721,138 In 1832 .................. 37,048 In 1864 .......... 6,773,256,173 In 1838 .................. 10,484,221 In 1876 .......... 2,189,886,067 In 1842 .................. 18,298,631 In 1879 .......... 9,704,053,446 In 1857 .................. 28,599,631 In 1880 .......... 17,224,145,028

At the last-named date, however, the net debt—deducting the cash in the treasury—was £75,915,079 dollars; and of the whole, £41,000,000 dollars, or the interest on the whole Pacific railways, which pay over 5 per cent., are included to the amount £64,629,112 dollars.

DEBT OF THE CHIEF EUROPEAN COUNTRIES.

Austria-Hungary—France, 1889 .......................... £234,928,193 Austria .......................... 89,115,880 Italy, 1861 .......................... 572,560,000 Hungary .................. 167,789,388 Portugal, 1889 .......................... 351,206,000 Belgium, 1890 .......................... 96,599,435 Russia, 1888 .......................... 436,290,720 Denmark, 1890 .................. 30,574,000 Spain, 1888 .......................... 266,900,000 Germany, 1888 .................. 16,600,000 Sweden, 1890 .......................... 1,357,287,307 Prussia, 1890 .......................... 290,250,218 Norway, 1891 .......................... 6,458,830 Bavaria, 1890 .......................... 67,075,729 Switzerland, 1892 .......................... 2,194,297 Saxony .................. 32,185,567 Turkey, 1890 .......................... 186,000,000

The debt of Brazil is said to be £10,000,000; of Japan, £20,452,600; of Chili, £17,524,600; of Mexico, £16,700,000; of China, £12,556,000.

Hamilton, An Account of the National Debt Conversion Act, 1825, and the National Debt Redemption Act, 1889 (1889); Fenn's Compendium of the Funds (ed. by Nash).
**National Gallery**

The principal repository of the pictures belonging to the British nation. The present building, which was intended to accommodate the Royal Academy of Arts, was erected in Trafalgar Square, London, and was finished in 1838 at a cost of £100,000, but was enlarged in 1859, in 1863, and in 1876. The nucleus of the National Gallery was the Angerstein collection of thirty-eight pictures, purchased in 1824 for £57,000, and subsequently increased by Sir R. Hayley's bequest of 157 pictures, and the bequest of Joseph M. W. Turner, R.A., in 1856, embracing 105 works in oil and an immense number in water-colours and pencil by his own hand. The entire collection now consists of over 2,200 pictures. There are catalogues to the Gallery by Blackburn (1877, 1879), E. T. Cook (3d ed. 1890), and others, and the *Pall Mall's Half-holidays* at the National Gallery (1890). The Royal Academy of Arts, which used to have its headquarters here, is now established at Burlington House.

The National Portrait Gallery, founded in 1836, was established at South Kensington in 1869, but removed on loan to the Bethnal Green Museum in 1883. Hence it was finally transferred in 1896, to occupy a handsome suite of buildings erected for it at the rear of the National Gallery. The gallery's director, until 1924, was the celebrated first director, Sir George Scharf, K.C.B. (1820-95).

There are also National Galleries of Art in Edinburgh and Dublin; the great public collections of Paris, Berlin, Dresden, Munich, Florence, Rome, &c. are mentioned in the articles on those cities.

**National Guard**

An organisation for local defence, at the disposal of the municipalities, not of the crown. Such a burgher guard had long existed in many French towns, but it was introduced into Paris only in July 1789, during the Revolution, when the revolutionary leaders decreed the formation of a national guard for Paris of 48,000 citizens; and ere long there were 300,000 for the kingdom. Duguesclin, the revolutionary commander, was sometimes supine, sometimes they withstood the most violent insurrectionists. In 1794 they were the most devoted adherents of Robespierre. In 1795 they assisted in dispersing the people, and were themselves reorganised so as to exclude turbulent elements, none but men of substance being allowed to serve; they even became royalists in feeling, and, rebelling against the convention, were defeated by Napoleon and the regular army, and practically ceased to exist. Napoleon re-established a national guard or militia, but, after various vicissitudes in 1815 and 1816, it has been wholly superseded by the military reorganisation since 1870.

**National Hymns**

The origin of the English national anthem has been a subject of controversy since the end of the 18th century, and is still involved in obscenity. 'God save the King' was first printed in the *Harmonia Anglica* of 1742, without name of author or composer, varying slightly from the present version; and in 1745, during the Scottish rebellion, it became the tune of a national song of it being sung nightly at Drury Lane and Covent Garden Theatres with great applause. Of the numerous claims to its parentage, the view supported by most, and by several eminent writers, attributes it, both words and music, to Henry Carey (1760-1820), who commenced them about 1740. The evidence for this is given in Chappell's *Popular Music of the Olden Time*, and Chrysander's *Jahrbücher*, vol. i. But Mr W. H. Cummings, who thoroughly beat out the subject in a series of papers in the *Musical Times* in 1878, entitled to the greatest weight, considers this evidence unsound; and he arrives at the conclusion that the music has been adopted (but when, and by whom, we shall probably never know) from an 'Ayre' by Dr John Bull (q.v.), found (without words) in a collection of music by him once in the hands of Dr Kitchen; afterwards of Richard Clark, the original of which seems to have disappeared. See also a paper by Major Crawford in the *Dictionary of Hymnology* (1891), by the Rev. John Julian.

The hymn was translated into German by Heinrich Harries, a Hofmeister clergyman, and sung to the original air of an 'Ayre' by John Bull, in honour of the birthday of the king of Denmark in 1790; and an adaptation from these words, made in 1793 by Dr H. G. Schumacher, beginning 'Heil dir im Siegerkranz', has ever since been in use as the Prussian national hymn. It called forth the admiration of Beethoven and Haydn, and moved the latter to compose the Austrian national hymn, which was first sung on the Emperor Franz's birthday in 1797. The words now used, beginning, 'Gott erhalte Franz den Kaiser,' are by Baron Zeilitz; the original words were by Hartmann. The Hungarian have two national hymns—the *Székes* ('The Appeal'), beginning 'Be true to the land of thy birth,' written by Vörösmarty (1800-55), the creator of Hungarian poetry of the Romantic school, and composed by Benjamin Egressy, an actor and eminent composer of sacred music; and the *Magyar Hymnus*, written by Kólesy and composed by Francis Erkel. The Rákóczi march, by an unknown composer, dates from the end of the 18th century. The simple and dignified Russian national anthem dates from 1830, and is the work of D. S. Bantius. The Danish, which is the *Kong Christian*, the words are by Ewald and the music by Johann Ernst Hartmann (1726-91). There are several claimants to the honour of being the Norwegian national anthem, of which may be mentioned 'Sønner af Norge,' written about the beginning of the 19th century, by C. Blom; the modern 'Ja, vi elsker dette Landet' (Yes, we love this land), words by Bjørnum, music by R. Nordraak. The Swedish hymn, 'King Karl, the young hero,' was written by Esaias Tegner (1782-1846). The Dutch, 'Wimel vuelts,' was written by J. W. Wilms. *La Brabanconne*, the Belgian revolutionary song of 1830, was written by Jennes, a Brussels actor, and composed by Campenhout. The *Marseillaise* (q.v.) of the French was written and published in 1792 by Claude Joseph Rouget de Lisle (1760-1836), and received its name from being sung by the volunteers from Marseilles who took part in the movements in Paris in that year. Various doubts have been thrown on de Lisle's authorship of the tune, but those were excluded by his deposition before the Committee, signed by his nephew in 1865. The Portuguese *Hymno constitucional* was composed by Dom Pedro I., emperor of Brazil. Though scarcely to be classi-
fied as a hymn, 'Yankee Doodle' is the American air, notwithstanding the more recent rival claims of 'Hail Columbia' and 'The Star-spangled Banner,' neither of which have high intrinsic merit or have taken any great popular hold. More like a hymn is the song 'American,' which is sung to the tune of 'Rule, Britannia!' in King,' The origin of 'Yankee Doodle' is as obscure and disputed a point as that of God save the King.' The most probable account ascribes to the tune an English origin, and the words to Dr Schuckburgh, an army surgeon, about 1753, soon after which, during the American war, it began to be extensively into vogue. It was first printed in Arnold's opera, Two to One, in 1784.

National Park. See YELLOWSTONE, and YOSEMITE. In Canada a domain 26 miles by 10 in extent has been set aside as a national park at Banff in Alberta (by rail 592 miles N.E. of Vancouver and 590 by N. of Winnipeg). It embraces one of the most beautiful sections of the Rocky Mountains, contains hot sulphur-springs, has a handsome railway hotel, and is popular as a pleasure-resort. Roger's Pass, 135 miles to the west, is also reserved as a government park. See also TAGARA.

Nations, LAW OF. See INTERNATIONAL LAW.

Nativity. See Astrology.

Natrolite, one of the most common of the group of minerals known as Zeolites (q.v.).

Natron, or Trona, an impure sesquicarbonate of soda, which always contains sulphate of soda and chloride of sodium. It is obtained from the margins of lakes in Egypt, Siberia, Tibet, &c., and from the borders of the Black and Caspian Seas.

Natron Lakes, eight in number, are in a depression to the west of the Danubia branch of the Nile. The locality is renowned for four monasteries, from whose libraries of Arabic, Coptic, and Syriac MSS. various European collections have been enriched. In the time of St Pachomius 5000 anchorites dwelt here.

Natterjack. See Toad.

Natural History, in its widest and oldest sense, includes all the concrete sciences, but psychology and sociology have been separated off at the one end of the series, physics and chemistry and all their branches at the other, so that natural history became synonymous with the science of living beings. More frequently, it simply means zoology, especially in so far as that is concerned with the life and habits of animals. See Biology, Botany, Evolution, Science, Zoology.

Naturalisation is the process whereby an alien is invested with the privileges and made liable to the obligations of a natural-born citizen. It implies the renunciation of one political status and the adoption of another. Formerly many states absolutely refused to recognise any act of naturalisation as exempting the party naturalised from the consequences of his allegiance. Thus, the maxim of English common law: Nemo potest everti in se exilio, that is, after adopting a new political status, and rendered him liable to the penalties of treason if found in arms against his native country. The existence of this principle gave rise to many disputes, more particularly between Great Britain and the United States. It was not, however, till the Naturalisation Act of 1870 that the doctrine of the indelibility of natural allegiance was formally abandoned by Britain. In the same year a treaty was entered into between Great Britain and the United States, which provided that British subjects becoming naturalised in the United States should be treated in all respects as United States citizens; and a corresponding provision was made with respect to United States citizens becoming naturalised in British dominions.

The conditions on which naturalisation will be allowed by the state to which the applicant seeks admission are of course very different in various states. Great Britain naturalisation is effected either through a special act of parliament or under the Naturalisation Act, 1870 (33 and 34 Vict. chap. 13). This statute, wherein are embodied the present regulations with reference to naturalisation, provides that a naturalised citizen of the United Kingdom for five years, or has for that period held service under the crown, can obtain a certificate of naturalisation from one of the principal secretaries of state. On the granting of this certificate he is entitled to all political and other rights, powers, and privileges, and is subject to all the obligations to which a natural-born British subject is entitled or subject. The only qualification is that he shall not, when within the limits of the foreign state of which he was previously a subject, be deemed to be a British citizen unless he has resided in that state five years, and his birthplace has the power of making their own regulations on the subject of naturalisation, but such regulations have effect only within the limits of the colony. In the United States a foreigner must make a declaration on oath of his intention to become naturalised. The declaration may be taken before any superior, district, or circuit court, and the applicant must renounce any title of nobility. After the lapse of two years from the date of this declaration, and after five years' residence in the United States, he becomes an American citizen, and a certificate of naturalisation can be obtained.

There is, however, no uniform system of registration of such certificates, and, as there are about 3000 federal and state courts having power to grant them, great difficulties sometimes arise in proving naturalisation. In France a foreigner who has obtained permission to become domiciled in France is entitled to letters of declaration of naturalisation after three years' residence. Also, by the French Naturalisation Act, 1889, a foreigner who has resided in France for ten years may at once be naturalised. Where no preliminary requirements are laid down, naturalisation can be conferred only by the highest administrative authorities; the applicant must show that he is at liberty, under the laws of his native country, to change his nationality, or, if he is a minor, that his father or guardian has given him the requisite permission, that he is leading a respectable life, that he is domiciled in Germany, and that he has the means of livelihood. In all countries a married woman is held to be a citizen of the state of which her husband is for the time being a subject, and the naturalisation of a father carries with it that of his children in minority. In countries where military service is compulsory naturalisation in fraud of this either is prohibited or renders the offender liable to imprisonment, if he returns, and forfeiture of all property subsequently acquired in his native country.

Certain states of the United States and of Great Britain may be acquired by the issue of letters of denization granted by the crown; and for this no previous residence is required. A denizen acquires his limited privileges as from the date of the letters, and not from the date of his birth; a naturalised citizen must hold the same position as if he had been from birth a British subject. The difference was important so long as aliens could not inherit land; for a denizen, being without inheritable blood, could not inherit land, nor could his issue, born before his deniza- tion, inherit it from him. Since the Naturalisation
Act has swept away all the disabilities to which aliens were subjected in the taking, holding, and inheriting of land (see ALIEN), the distinction between alienization and naturalisation is of little practical importance. It is, however, to be observed that the statute (12 and 13 Will. III. chap. 2, sect. 3) which disqualifies a denizen from being a member of the Privy-council or of parliament, and from holding any office of trust, civil or military, still remains in force.

See the standard works on international law: Nationalit, by Chief-justice Cockburn (1809); and La Nationalité, by Cegonan (2d ed. 1890).

Naturalism, a term once used as almost equivalent to Deism, and sometimes for nature-worship, also for brutish defiance of moral law, is now usually employed as synonymous with Realism (q.v.) in art, literary or other.

Natural Philosophy is a term still frequently employed in Great Britain to designate Physics (q.v.), or the branch of physical science which has for its subject those properties and phenomena of bodies which are unaccompanied by any essential change in the bodies themselves.

See Science.

Natural Selection. See DARWINIAN THEORY.

Natural Theology. See APOLOGETICS, and THEOLOGY.

Nature-printing, a process by which engravings or plates answering thereto are produced by taking impressions of the objects themselves, and printing from them, invented or improved about 1833 by Alois Auer of Vienna. Suitable objects for them must have tolerably flat surfaces—such as dried and pressed plants, embroidery and lace, are placed between a plate of copper and another of lead, both worked smooth, and polished; the plates are drawn through a pair of rollers, under pressure; then, when the plates are separated, it is found that a more or less perfect impression of the object has been made in the leaden plate. This may be used directly as an engraved plate, if only a very few impressions are wanted; or a facsimile of it may be obtained in copper by the electrotype process. Nature-printing has been superseded by photographic methods. See ILLUSTRATION OF BOOKS, PHOTOGRAPHY.

Naucratis, an ancient city of Egypt, situated in the Nile delta, near the modern village of Nebirish, 47 miles SE. of Alexandria, existed in the 3d cent. B.C. It was the only city in Egypt at which the Greeks were allowed to trade; was celebrated for its artistic pottery; and was a centre for the worship of Aphrodite. The site was discovered by Flanders Petrie in 1884, and excavated by him in that and the following year. His monograph Naucratis (1880) gives an account of the ruined temples and the many valuable archaeological discoveries made on this site.

Naugatuck, in Connecticut, on the Naugatuck River, 22 miles by rail N.W. of New Haven, contains the factory of the Goodyear Glove and Rubber Company, and also manufactures cutlery and iron-wares. (Pop. 1890) 10,541.

Naumachia, a Greek word signifying literally swimming or bagnio, among the Romans, a spectacle which consisted in the imitation of a naval battle. Julius Caesar was the first to introduce a naumachia into Rome, 48 B.C., causing a portion of the Campus Martius to be dug to form a lake, on which the spectacle came off. Augustus also made an artificial lake near the Tiber for the same purpose, and Claudius employed Lake Fusinus, where on one occasion 19,000 combatants were engaged for this purpose. The combatants were for the most part either captives or condemned criminals. These naumanchae were not sham-fights any more than were ordinary gladiatorial combats; but sides were drawn, and the contest was for dear life until one was utterly overpowered.

Naumburg, a quaint old town of Prussian Saxony, on the Saale, in an amphitheatre of vineyard hills, 30 miles by rail S.W. of Leipzig. Of its six churches, the triple-towered cathedral (1207-42) is a noble Romanesque and Gothic structure. The manufactures include ivory carvings, combs, lossiery, wine, &c. The yearly 'cherry feast' commemorates the raising of the siege of Naumburg by the Hussite leader Procopius in response to the supplication of the children (28th July 1432); but recent historians cast doubt on the whole episode. The seat of a bishopric (1680-1564), Naumburg suffered much in the Thirty Years' War; in 1814 it came to Prussia. (Pop. 1875) 16,253; (1870) 19,739. See works by Puttrich (1842) and Mittelhale (1881).

Nauplia, a small fortified town and seaport with an excellent roadstead in the Morea, Greece, at the northern extremity of the Gulf of Argos or Nauplion of the ancients, S. of Corinth. At an early period it was the port and arsenal of Argos. In the 13th century it was occupied by the Venetians (who called it Napoli di Romania), and it was taken by the Turks in 1540. From 1824 to 1835 it was the capital of Greece, and had a population of upwards of 30,000; but after the removal of the court to Athens it fell into decline. Pop. 4,508.

Nautilus. See CRUSTACEA.

Nausea, a distressing sensation always referred to the stomach. It is unattended by pain, but is usually accompanied by a feeling of general languor or debility, a small and often irregular pulse, a pale, cool, and moist skin, general muscular relaxation, an increased flow of saliva, and a sensation that vomiting will supervene. This is most commonly a direct symptom of disease or disorder of the stomach, but sometimes it is a very important indirect symptom of disease of some part at a distance from the stomach—as, for example, the brain or the kidney. The nausea which is so troublesome to pregnant women is due to the irritation excited by the enlarged uterus being reflected by nervous agency to the stomach. Sea-sickness is separately discussed.

Nautch Girls, or BAYADÈRES, public female dancers in India and the East Indies. Their performances constitute a principal part in the spectacular entertainment called a nautch or natch.

Nautical Almanac. See ALMANAC.

Nautilus, a remarkable mollusc in the class of Cephalopods, the only surviving member of a race once abundant. It differs conspicuously from the other extant Cephalopods or 'cuttle-fish' in possessing a shell, within the outermost chamber of which it lives, while the holes of the 'foot' round about the mouth bear numerous tentacles retractile into the mouth. The body, 'constriction' consists in the fact that the eyes are open seas without cornea or lens, there are four gills and four kidneys, and there is no ink-bag. The spiral shell, coiled in one plane like that of the water-snail Planorbus, differs from this in being chambered; moreover, the foot or ventral side of the body and the animal is unsuitable in Nautilus, towards the inside in Planorbus. When young the Nautilus lives in a small shell bent like a horn; with growth this is increased spirally, but as the animal periodically draws itself onwards and closes a door behind it, a chambered spiral results, in which the animal is kept the centre. The successive chambers are all connected, however, by an organic, partially calcareous tube; and all except the outermost, in which the animal
lives, are filled with gas—an apparently a mixture of oxygen and nitrogen somewhat different from air. The outside of the shell is covered with a thin

organic layer, beneath which there is a porcelain-like stratum with bands of colour, while internally the line has the usual mother-of-pearl structure, the lustre of which, often artificially exposed by the use of acids, has earned for the animal its common name of Pearly Nautilus.

Though the Nautilus seems to have been known to Aristotle, and though the shells have always been familiar, our knowledge of the animal itself is almost wholly due to the investigations of Owen, and to some interesting observations (1785) by the Dutch naturalist Humphins. The rarity of specimens, so evident from the fact that only one was collected on the Challenger expedition, is mainly due to its habitat in somewhat deep water. But it must also be noted that the natives of Fiji, the New Hebrides, the Moluccan islands, &c. catch the animal in lobster-pots and eat it with relish. The Nautilus probably creeps or gently swims along the sea-bottom, feeding on crustaceans and the like; but it is also seen floating on the surface, probably washed up by storms and injured by the waves. The species best known is Nautilus pompilius, but there are probably four or five others, while the fossil relatives are reckoned in hundreds.

The Paper Nautilus (Argonauta) is a very different animal, like an octopus except that the female bears a beautiful, translucent, ribbed shell in which the eggs are sheltered. But this shell is not in any way comparable to that of the Nautilus or of other molluses; it is a cradle, not a house; it is secreted and embraced by two broadened dorsal 'arms,' not by the mantle; it is unchambered and peculiar to the females. The Argonaut was credited by Aristotle with the power of lifting its broad arms, and of thus sailing before the wind, but there is no truth in this fancy often reiterated by poets and naturalists. For the Argonaut squirts water from its funnel and swims backwards like any other cuttle-fish, or else creeps along the bottom. At the breeding season it is a pelagic surface swimmer in tropical seas, at other times it seeks the depths. The male measures little more than an inch in length, only about a tenth the size of his mate, and he is also notable for the modification of one of the arms into a detachable sac of spermatozoa, formerly mistaken for a parasitic worm. Some half-dozen living species are recorded. See CEPHALOPODA, CUTCLE-FISH.

Nauroo (from Ible, nārār, 'to be beautiful!'), a village of Illinois, on the east bank of the Mississippi River, 14 miles above Keokuk. It was built by the Mormons (q.v.) in 1840, and in a few months contained a population of 15,000. Its principal feature was a great temple of white limestone (1841–45); but it had also mills and factories, and the beginnings of a university, and was for a few years a prosperous and busy port. After the expulsion of the Mormons in 1846, the temple was half destroyed by fire in 1848, and further ruined by a tornado in 1850. The town was for a time occupied by French Socialists, and has now only 1921 inhabitants. —The Nauvoo Legion was a Mormon military organisation, embracing all the males between the ages of sixteen and fifty, founded here in 1840, and reorganised in Utah in 1857. In 1870, when it mustered for the last time, it numbered about 13,000 men.

Naval Cadets. See CADET, MIDSHIPMAN.

Naval Reserve, Royal, is a sort of militia auxiliary to the royal navy. It is a force held in high esteem by naval men, and is considered an extremely valuable reserve of trained men ready to man the fleet in case of emergency. The act under which the force was instituted in 1859 authorises the engagement of 30,000 men, each for a period of five years, and provides that each shall be rated for two years, or one year to the use of arms and in naval gunnery, either in ships of the navy or on shore. In case of national emergency, these men can, by royal proclamation, be called out for service in the navy in any part of the world, for periods not exceeding five years. While training and while called out for actual service, the men receive the same wages as corresponding ratings in the royal navy; and in addition they receive a retaining fee for every year of training completed, the amount of which is regulated according to the class of the reserve in which they are enrolled; this is £6 a year for men in the first class, and £2, 10s. with a suit of clothes for the second class; boys in the third class receive no retainer, but the fourth class, consisting of stokers, receive £5 a year. On actual service—whether three years—whether uninterrupted service or at broken intervals—the volunteer becomes entitled to twopence extra per diem. The man can terminate his engagement at the end of five years, unless on actual service, when he may be required to complete five years of such service before discharge. During the continuance of his engagement he must not embark on voyages which shall entail a longer absence from the United Kingdom than six months, unless with special permission of the Admiralty. The periods for training are made as
far as practicable to suit the sailor's convenience: he may break the twenty-eight days into shorter periods, none being less than seven days. Penalties are enforced if men fail to attend; and failure after proper notice to come up for actual service is held equivalent to desertion. While training or on duty, the men are liable and after the publication, as they are entitled to all the rights and privileges, of regular seamen. The men considered most desirable are (1) those having fixed residences, and personally known to the registrar or his deputy; and (2) men having regular employment of one kind or another in which the business of which they bring them back to the same ports at frequent and known intervals. In 1891 the system of the Reserve was extended to officers of the merchant-service, certificated masters and mates being respectively granted commissions in the Naval Reserve as lieutenants and sub-lieutenants. The holders are required to train for twenty-eight days annually on board Her Majesty's ships, and are liable to be called out for actual service when required. The number of these officers allowed by regulation is 130 lieutenant and 270 sub-lieutenants. The Royal Naval Reserve now contains four classes of men. (1) The first class comprises men under thirty years of age, who must prove at least six years' service within ten years, and of these six years' service two at least as able seamen in foreigngoing vessels, one as a boatman. He must durat that it is their intention to follow the sea-service for a period of at least five years. Six months' service as skipper or second hand in first-class fishing-vessels in the English Channel and North Sea, are accepted in lieu of two years' service as able seamen. Men discharging their duties as able seamen with good characters may be enrolled in the first class up to thirty-five years of age, also men who have previously served in the Royal Naval Reserve. (2) The second class contains men with proper qualifications between nineteen and thirty years of age, who must have been at sea on foreign-going, coasting, or fishing vessels for three years, of which at least six months must have been with the grade of ordinary seaman; and they must sign a declaration that it is their intention to follow the sea for a period of at least five years. Apprentices who have completed their indentures for a term of not less than three years may be enrolled in this class without further proof of service. (3) The third class comprises boys, not under fifteen nor above sixteen and a half years of age, who have been eighteen months under training in a mercantile training-ship, or have been educated at Greenwich Hospital, are under engagement to join a merchant-ship, are physically and mentally qualified, and can show proficiency in navigation and seamanship; they must prove the fitness of good character from the captain or superintendent. In the case of the Marine Society's ship Warspite, boys will be received with nine months' training. They may be promoted to the second class at the age of nineteen after six months' service at sea; and in due time to the first class. (4) The fourth class is that of firemen. A candidate must be over twenty and under thirty-five years of age; he must produce certificates of good character, conduct, and ability as fireman from his last employer, for not less than six months in foreign-going or regular coasting vessels of any kind, and one year in a foreign-going vessel. He must, in his application. Every enrolment is for five years; and when a man is promoted to a higher class he must re-enrol. The annual training may be accomplished either on board a ship of war or at a Naval Reserve battery. In 1890 the total number of reserve men drilled was 18,809, of which number 8294 were receiving an extra penny a day as trained men. The officers of all ranks provided for in 1895 numbered 1400 and the men 23,700, the cost amounting to £215,600. Besides the Royal Naval Reserve, there are other Naval Reserve forces at command of the Admiralty. The Naval Reserve of the United Kingdom is the corps of Royal Naval Artillery Volunteers has ceased to exist; but there is still a force drawn from amongst the seamen pensioners (see Pensions). Petty officers and seamen of the navy, on being pensioned for length of service, may, if under forty-six, after two years' or more service, be hired to an Active Reserve. They must serve fourteen years annually, and on reaching fifty years of age get the Greenwich Hospital age pension and are exempt from further drill.

Naval Tactics. See Tactics (Naval).

Navarre (Basque Navarra, Gabo, 'mountain plain, high land, country'; there is also a Basque word Nabarra, 'variegated'), formerly one of the kingdoms which arose in the Pyrenees after the downfall of the Goths, has since 1512 been divided into Spanish Navarre, and French or Basque Navarre (now Basse Pyrénées). Spanish Navarre, by far the greater, is bounded N. by France, E. by Aragon, S. partly by the Ebro, partly by Castile and Aragon, and W. by Alava and Guipuzcoa. The area is somewhat over 6000 sq. m.; pop. 304,122, or 50 to the square mile. It is one of the most varied provinces of Spain in surface and climate. Within sight of the Atlantic at its north-west corner, the rainfall is there one of the heaviest in Europe, while in the south-east the steppes of the Barénes Reales are almost sterile for want of water, and at Tudela we encounter Moorish modes of irrigation, supplemented by the canal of Charles V. The mountains of the northern frontier range, west to east, from 3000 to 8000 feet of altitude; in the interior they reach occasionally 5000. With the exception of the Bilbao, which enters the Atlantic at the inner angle of the Bay of Biscay, the numerous rivers of Spain flow at right angles to the Pyrenees, and are all affluents of the Ebro; the principal are the Aragon, Arga, and Ega. The mountain-valleys are narrow but fertile. By the energy of the Basques, who do not live like the Spanishiards only in towns and villages, cultivation is pushed everywhere. The main productions are maize, wheat, chestnuts, apples, and a strong red wine. Cattle abound, but not many sheep or horses. Minerals are found in the Pyrenees, and mines of argentiferous lead, copper, and iron are worked; rock-salt also is found in the provinces. The wild animals include the bear, wolf, red-deer, ibex (ibex) in the mountains of the Aragonese frontier; foxes, wild cat, genette, otter, marten, &c. are in sufficient numbers to make commerce of their skins. The population of Navarre is generally bilingual; from a little to the south of Pampolna northwards Basque prevails;
to the south Spanish only is spoken. Until now Spanish has encreased so far more on Basque in Navarra than has French in Basse-Navarre.

In the year 1126 this town was founded by the king called the Iberian Vascones, who have given their name both to Basques and Gascons. Within historic times there has been a strong Celtic element in the country. The capital, Pamplona (Pampepota), recalls the Roman Trimivir, but the older native names (ibarresta, etc.), are often on books printed at Pamplona. The subjection of the Vascones to the Visigoths was nominal only. On the downfall of the latter and the incursion of the Arabs the mountains of Navarre became one of the early centres of resistance and of reconquest. From the native chiefs, or counts, arose the first dynasty of Navarre—Garcia Jimenez (860) to Sancio the Strong (1234). The history of Navarre is full of interest. In 778 the rout of Charles'magne's rear-guard, and the death of Roland at Roncesvales, furnished a theme for countless poems and romances. With Aragon and Castile Navarre shares the honour of being one of the first countries in which parliamentary rule with representation of towns and commons (Universidades) obtained. The Cortes (Curieiee) arose out of the Councils, and there was regular representation of the provinces in the Congresses of the 12th century. During this period Navarre gained its name and modern limits, but under Sancio the Great (1028-35), and again (1109-34) under Alfonso I, it seemed as if the union completed under Ferdinand and Isabel would have been taken place three times. During this period Pamplona, the Strong left no male heirs, and the future succession of Navarre was singularly broken from the same cause. The crown passed to Thibaut, count of Champagne, through the younger daughter. The end of this period was marked by the marriage of Blanche of Castile to the Black Prince, who passed through his dominions to Navarrete. Wellington blockaded Pamplona, and marched through Navarre in 1813-14.

Nave. See CHURCH, GOTHIC ARCHITECTURE.

Navette (Fr. navette), a garden vegetable much cultivated in France and other parts of the continent of Europe, although little used in Britain. It is by some botanists regarded as a cultivated variety of the Turnip (Brassica napus), or Rape (q.v.), whilst others refer it to B. campestris. The garden Chinese or Wild Navette, the species which is also supposed to be the original of the Swedish Turnip (q.v.). The plant is the swollen root, which is rather like a carrot in shape. Its colour is white. Its flavour is much stronger than that of the turnip. It succeeds best in a dry, light soil. The seed is sown in spring, and the plants thinned out to 5 inches apart. Wild Navette is extensively cultivated in the north of France and Holland for the sake of its seed, which yields Colza oil.

Navel Disease, in the horse, consists of an inflammation, often of a rheumatic character, of the small bone—the navicular—below which passes the strong flexor tendon of the foot. It is most common amongst the lighter sorts of horses, and especially where they have upright pasterns, out-turned toes, and early severe work to hard metal. It yields, given proper treatment, puning yet cautious gait, undue wear of the toe of the shoe, and projecting or 'pointing' of the affected limb whilst standing. Even when early noticed and in horses with well-formed legs, it is incurable; and when of several weeks' standing it leads to so much inflammation and destruction of the tendon and adjoining parts that soundness and fitness for fast work again are impossible. In order to reduce the pain and inflammation, rest should at once be given, the shoe removed, the toe shortened,
and the foot placed in a large, soft, hot poultice, changed every few hours. Laxative medicine and bran mushes should be ordered, and a soft bed made with old short litter. After a few days, and when the heat and tenderness abate, cold applications may be given on the bottom. Having done this, a blister may be applied round the coronet, and the animal placed for two months in a good yard or in a grass field, if the ground be soft and moist; or, if sufficiently strong, at slow farm-work on soft land. Division of the nerve going to the foot renders the action more and consequently laizzes the foot. This is useful in relieving animals intended for slow work. The operation, however, is not to be recommended where fast work is required, for the animal, insensible to pain, uses the limb as if nothing were amiss, and the disease rapidly becomes worse.

Navigators' Islands. See SAMOA.

Navy. The ancient method of naval warfare consisted in great part in the driving of beaked vessels against each other; and therefore skill and celerity in manoeuvring, as so to strike the enemy at the greatest disadvantage, were of the utmost importance. The victory thus usually remained with the best sailor. These vessels were propelled by oars, which were arranged in one, two, or three banks, according to size of ship; the oars were manned by men sitting or standing on platforms arranged above each other according to the number of banks; these with three banks of oars were called triremes. The earliest primitive fleets appear to have been the Phoenicians, Carthaginians, Persians, and Greeks; the Greeks had fleets as early as the beginning of the 7th century B.C.—the first sea-fight on record being that between the Corinthians and their colonists at Corcyra, 604 B.C. The early methods of which tactics appear to have distinctly been opposed to superior force, and with success, was that of Salamis (480 B.C.), where Themistocles, taking advantage of the narrowness, forced the Persian fleet of Xerxes to combat in such a manner that their line of battle but little exceeded in length the line of the much inferior Athenian fleet. The largest triremes in the Persian fleet were manned by 200 rowers and 30 fighting men; there were 1200 triremes and 3000 smaller vessels, while the Greek fleet consisted of 496 triremes only, with a certain proportion of smaller vessels, and was enabled in inflicting a crushing defeat on the Persians. The Peloponnesian war, where 'Greece met Greece,' tended much to develop the art of naval warfare. But the destruction of the Athenian maritime power in the Syrian expedition of 412 B.C., left Carthage mistress of the Mediterranean. This power, however, gradually asserted itself, and after two centuries became omnipotent by the destruction of Carthage. For several following centuries the only sea-fights were occasioned by the civil wars of the Romans—the Aetna (q.v.) in 31 B.C. Towards the close of the Middle Ages the system of fighting with pointed prows had been discontinued in favour of that which had always coexisted—viz. the running alongside and boarding by armed men, with whom each vessel was crowded. Onagers, ballistae, &c., were ultimately carried in the ships and used as artillery; but they were little relied on, and it was usual, after a discharge of arrows and javelins, to come to close quarters. A sea-fight was therefore a hand-to-hand struggle on a floating base, in which the vanquished were almost as frequently drowned as killed.

The northern invaders of the empire, and subsequently the Moors, seem to have introduced afloat-sailing Galleyes (q.v.), warring both in small squadrons and singly, and ravaging all civilised coasts for plunder and slaves. This—the break-up of the empire—was the era of piracy, when every nation which had more to win than lose by free-booting sent out its cruisers. Foremost for daring and seamanship were the Norsemen, who penetrated in every direction from the Bosporus to Newfoundland. and bination being the only security against these marauders, the medieval navies gradually sprang up; the most conspicuous being, in the Mediterranean, those of Venice, Genoa, Pisa, Aragon, the Knights of Malta, and the Turks; and on the Atlantic seaboard, England and France.

Medieval Navies. In the Mediterranean, towards the middle of the 16th century, so powerful and so threatening had the Turkish fleet become that, after the Knights Hospitallers had been driven out of Rhodes by the Sultan Solymam I. in the year 1225, a combination of the Christian powers was formed for their defence; but in the year 1571 that the celebrated battle of Lepanto was fought, which broke temporarily the naval power of the Turks. The Christian fleet was composed of Venetian, Genoese, Spanish, and papal ships, under the command of Don John of Austria, with six Maltese galleys, and mustered over 200 vessels,
of which six were Venetian galleasses, which were larger and carried a heavier weight of metal than had yet been known in Mediterranean warfare. The ordinary galleys were about 106 feet long, 32 feet wide, and carried a crew of sixty or eighty men; they generally carried a 24-pounder forward and two 8-pounders on the poop. In the galleasses the rowers were covered by a narrow deck on which small guns were mounted. The Turkish fleet consisted of 240 galleys, but they were completely defeated, losing over 30,000 Turks were slain, and 15,000 Christians serving as galley-slaves in the Ottoman fleet were rescued from captivity. The confederates lost 15 galleys and 8000 men. The Venetian and Maltese fleets subsequently became the great naval powers, although sharing the sovereignty of the Mediterranean with the Turks; but during the close of the 16th and 17th centuries the naval power gradually fell into the hands of the English, French, Dutch, and Spaniards. 

carried by a few of the most highly trained of any navy in the world. The Italian fleets dates from the absorption of the kingdom of Naples by Sardinia in 1860. Since the disastrous battle of Lissa (1866), each successive Italian government has devoted large sums and much energy towards building up a powerful navy, and Italy may fairly claim now to rank as a first-class naval power, occupying a position next to France (see Italy). Among the Italian ironclads may be numbered ten of the largest and most powerful battle-ships afloat—viz. the Duodo and Dritto and the Italia and her seven sisters. All these ships carry four 110-ton guns in their turrets or barbettes, besides a powerful auxiliary armament, while the engines of the five latest of these ships are far more powerful than those of the best newly-designed English battle-ships, and are calculated to drive them at a speed of 15 knots an hour.

The Austrians, the victors at Lissa, have since 1840 possessed a small, but probably for its size one of the most efficient of the European navies, officers and men being most carefully and thoroughly trained. The Turkish navy, once the terror of the whole Mediterranean, has now sunk to a low ebb. In 1827 it sustained at the battle of Navarino a crushing defeat, from which it never recovered. At the outbreak of war with Russia in 1853, a division of the Turkish fleet was completely destroyed by a superior Russian force at Sinope; but as a result of the restrictions imposed on Russia after the Crimean war, and of the energy infused once more into Turkish naval administration by Admiral Hortart Pasha, its fleet was once more powerful and Russia and Turkey in 1877 the Russian fleet was effectually paralysed by the superior Turkish forces, which retained command of the Black Sea during the war. Since then, however, no new ships have been built, and in the present state of the finances of the country it is unlikely that the Turkish navy will play any important rôle again in the future.

The Russian navy was founded by Peter the Great, but, although it soon became a formidable one, it has never as yet distinguished itself or become an important factor in the numerous wars in which Russia has been engaged. After the battle of Sinope in 1853 the bulk of the Black Sea fleet was sunk by order of Prince Menschikoff, governor of Sebastopol, to block the entrance to the harbor, and the remaining ships were burned when the Russians retreated in September 1855. By the abrogation of the Black Sea portion of the treaty of Vienna in 1871 Russia regained a free hand once more in the Black Sea, and she has for some years been making strenuous efforts to resume her place in the world. Many of the ships which have been built, while others are in course of construction, as well as several cruisers of the most modern type, and she in her turn is once more mistress of the Black Sea.

NAVY OF THE UNITED STATES.—Simultaneously with the War of Independence, the Americans began to build ships, and during that war and the war of 1812 and 1814 their fleet maintained a glorious although unequal struggle with Great
Britain. The war of Secession, which broke out in 1860, however, found the United States navy at a low ebb, and although a large number of vessels were built during the ensuing four years, they were mostly gunboats for blocking purposes and monitors for coast and river work. The construction of the original Monitor, however, at that time by Captain Ericsson, and the good work she performed, in reality settled the type of the armed frigate-ship of the future. The first steps towards the construction of the modern navy were taken in 1883.

Since that time every process necessary to the construction and equipment of the most efficient vessels of all classes, their armour-plate, ordnance, and ammunition, has been perfected in the United States. The naval force on June 30, 1899, comprised 270 vessels built, building, and projected; of these, 50 were in construction, 20 were being planned, and 17 were unfit for service, leaving 149 vessels of all classes for active service. This number included 5 first-class battle-ships, of great displacement, heavily armoured and armed; 1 second-class battle-ship; 2 armoured cruisers, of great cruising capacity, with heavy armour and ordnance; 1 armoured ram; 6 double-turreted monitors, with heavy batteries, and 9 iron single-turreted monitors. There are also 13 armoured gunboats, on unprotected monitors; 20 gunboats, and 19 gunboats under 600 tons displacement, mainly on service in the Philippines; 1 sloop of war; torpedoes, tugs, despatch boats, &c. Of the vessels under construction and being planned (1899) there were 12 first-class ironclads, 14 ironclad armoured cruisers, 9 protected cruisers, 4 single-turreted monitors, 16 torpedo-boat destroyers, 15 torpedo boats, and 7 submarine torpedo boats. Some of the Spanish vessels captured or sunk during the Spanish-American war (1898) are in service. The personnel of the navy in 1899 comprised 134 commissioned officers, and 177 warrant and 4375 petty officers, 10,131 enlisted men, and 2,221 apprentices; total, 19,239. In 1899 the engineer and executive branches were amalgamated. The marine corps has 201 officers and 6,006 men.

The accompanying table will give a fair estimate of the comparative strength of the different navies of the world in 1890.

### The British Navy.

Alfred the Great was the founder of the English navy, having perceived the necessity of a fleet to protect the coasts from the swarms of pirates in the northern seas. A slight advantage gained by some ships of his over the Danes in 876 induced him to build long ships and galleys, which, as his countrymen were not competent to manage them, he manned with such piratical foreigners as he could engage. After he had driven out the Danes he applied his talents to improve his ships, and built vessels higher, longer, and swifter than before, some rowing more than thirty pairs of oars. Under his successors the number of vessels increased, and both Edward the Elder and Athelstan flogged many naval battles with the Danes. Edgar aspired to be lord of all the northern seas, and had from three to five thousand galleys, which he divided into three fleets, on the western, southern, and eastern coasts respectively. Ethelred II. enacted that every owner of 310 hides of land should build and furnish one vessel for the service of his country. William the Conqueror established the Cinque Ports, and gave them certain privileges, on condition of their furnishing fifty-two ships for fifteen days, carrying twenty-four men each, in case of emergency. Richard I. took one hundred large ships and fifty galleys to Palestine. King John claimed for England the sovereignty of the seas, and required all foreigners to strike to the English flag, an honour which was exacted by the English.
UNITED STATES BATTLESHIP "INDIANA"
admiral from the fleet conveying Philip II. of Spain off Southampton-water, when the latter was on his way to revenge Queen Mary; this honour was formally yielded by the Dutch in 1675 and the French in 1794, but the custom since the peace of 1815 has fallen into disuse. In the year 1293 a great naval action was fought in mid-channel with the French, when the English captured 230 sail; and Edward III. with the Black Prince at the battle of Sluys in 1340 defeated a greatly superior French fleet.

Henry V. had something of a navy; but Henry VII. seems to have been the first king who thought of providing a naval force which might be at all times ready for the service of the state. He built 14,906 men; but these were not all 'shipps royal,' for he encouraged the merchants to build large ships which were as much lighting ships as trading ones, and rated at 50 to 100 tons more than they measured. She raised the wages of seamen to 10s. per month. Signals were first used in this reign as means of communication between ships. In the reign of James I. lived the first able and scientific naval architect, Phineas Pett; he introduced the first system of building, and relieved the ships of much of their top-bamer, abolishing the lofty poops and forecastles. In 1610 he laid down the Prince-Royal, a two-decker carrying sixty-four guns; and in 1637 from his design he laid the Sovereign of the Seas, the first three-decker and the largest ship hitherto constructed on modern principles. She was 232 feet in length, of 1637 tons, and carried at first 130 pieces of cannon; being found unwieldy, she was cut down, and proved an excellent ship, but was burned in 1696. In this reign the navy was first divided into rates and classes. Cromwell left 154 sail, measuring 57,643 tons, of which one-third were two-deckers. He was the first to lay before parliament annual estimates for the support of the navy, and obtained £100,000 for that purpose. During the Protectorate Henry Pett, son of Phineas, built the Constant Warwick, the earliest British frigate, from a French design and pattern. The Duke of York, afterwards James II., assisted by the celebrated Samuel Pepys, as Secretary, did much for the navy. He appointed a new comptroller when he came to the throne, with which he joined Sir Anthony Deane, the best naval architect of the time, who essentially improved the ships of the line by copying from French models; at this time, and during the 18th century, naval architecture was zealously studied in France, and the English officers and sailors were so sensible of their inferiority that even to the beginning of the 19th century all our best ships were either captured from the French or copied from them. At the Revolution of 1689 the fleet was in excellent condition, with sea stores complete for eight months for each ship. The force consisted of 184 vessels, carrying 69,390 guns, and 42,000 men, whereof nine were first-rates.

William III. added greatly to the navy, which numbered at his death 272 ships of 159,020 tons, with the annual charge being £1,056,016. The dockyard at Harwich, which lay in a considerable town of Devonport (q.v.), was also established during his reign (see also the article DOCKYARDS, ROYAL).

At the death of Queen Anne in 1714 the number of ships was less, but the tonnage relatively greater, there being 198 ships, carrying 10,600 guns, the tonnage being 150,640. In 1747 a naval uniform was first established. The navy increased rapidly during the reigns of the first two Georges, and at the accession of George II. consisted of 127 ships of the line and 192 of fifty guns and under, measuring 321,104 tons, and manned by 70,000 seamen and marines. The navy was kept in a high state of preparation, and, when in February 1793 the French Republic declared war against England, in a few weeks fifty-four ships of the line and 98 of eighty-two guns put to sea completely equipped. The whole fleet in 1793 consisted of 122 ships of the line, 97 frigates, and 102 sloops and smaller vessels, manned by 85,000 seamen and marines. The navy of France had never been so powerful; it amounted to above 300 vessels at the end of the war, and 200 more were in addition ordered to be built. The English had about 115 sail of the line fit for service; but the majority of the French ships were larger and finer and carried heavier guns on their lower or principal battery. The following abstract will

---

Fig. 1.—The Great Harry.
show the losses on both sides up to the peace of Amiens (1802).

Captured. Destroyed.

British ships of the line... 5 0
Smaller vessels... 37 9

Total... 42 9

French ships of the line... 33 11
Dutch... 13 0
Spanish... 2 0
Dano-Swedish... 2 0

Total... 50 13

French smaller vessels... 200 44
Dutch... 72 17
Spanish... 57 10

Total... 245 71

Grand Total... 443 76

This estimate does not include 807 privateers, chiefly French, taken and destroyed. Of the above, 50 sail of the line and 94 under that size were added to the British navy.

During the peace of Amiens preparations for war were actively continued on both sides, and when war broke out again in March 1803 the British fleet consisted of 153 ships of the line and 411 under that size, manned by 120,000 seamen and marines. 'In the year 1803,' to quote the words of Alison, 'the British fleet was at the zenith of its power, and Great Britain first appeared in the field on a scale adequate to her mighty strength. With a fleet of near 1100 vessels, including 240 of the line, manned by 140,000 men, she blockaded every hostile harbour in Europe, and still had 37 ships of the line to strike a blow at the Scheldt.

With 100,000 regular troops she maintained her immense colonial empire; with 191,000 more she ruled India; with 400,000 militia she guarded the British Isles; while her fleet could convey yet another 100,000, with which she manoeuvred, at once, Antwerp, Madrid, and Naples; while Lord Minto, the Governor-General of India, announced in his dispatches with well-founded pride that 'from Cape Comorin to Cape Horn a French flag could nowhere be found flying.'

The following abstract shows the losses on each side from 1803 to the end of the war, during which 33 sail of the line and 68 under were added to the British navy.

Captured. Destroyed.

British ships of the line... 0 0
under... 83

Total... 83 7

Enemies' ships of the line... 55 14
under... 79 23

Total... 134 37

Since the peace in 1815 the number of vessels has been greatly diminished, although their power has vastly increased.

The progressive augmentation of size in vessels may be judged from the increase in first-rates. In 1677 the largest vessel was 136 tons, the largest of the line 260 tons; by 1720, 1800 tons had been reached; by 1745, 2000 tons; 1808, 2616 tons; 1833, 4000 tons; 1860, 6959 tons—the Victory, the last three-decker built in England; while the Warrior, the first treenailed built in Britain, and launched in 1861, is 9210 tons. The building of the latter was preceded by the construction of the Baltic ships, which in 1840 were 14,000 tons. We may observe by the way that up to the year 1860 the ships were practically the ships of the last two centuries, improved and developed largely certainly by the introduction of steam, of increased tonnage and of better lines, but still the same ships and the manner of armament with but little improvement to record over the beginning of the century. In 1786 the Victory was launched; she was at that time the largest three-decker in the English service; she is 186 feet long, has a tonnage of 2100 tons, and carried 160 guns, the bulk of which were long 32-pounders. Angling 66 guns in 1850 the ship in the Mediterranean was the screw three-decker, the Marlborough; she was 282 feet long, 6100 tons, and carried 121 guns; her lower-deck guns were 65 cwt. 8-inch shell guns throwing a shell with bursting charge inclusive of 56 lb., while her remaining 68 guns were 32-pounders, with which the Victory had been armed nearly a century before. But since 1860 a vast revolution has been effected in our naval forces, and it seems almost incredible that in so short a space so great a transformation should have taken place. The ships and armament of the wooden walls of old England are things of the past, and, instead of the graceful frigate and stately line-of-battle ship, our battleships of the present day are floating castles protected with massive armour, crammed with engines, without which they could neither move, fight their guns nor be even habitable for their crews, the breathing air below being driven down by fans worked by steam; while the 32-pounders and 10-inch shell guns have given place to 67-ton and 110-ton rifled guns, throwing projectiles of immense weight.

The 67-ton gun as a propelling power is the agent by which this change has been effected. From 1841 a gradual substitution of steam for sailing vessels began, which was not completed, however, until 1890—in fact, the last sailing frigate in commission, the Calypso, only returned from the Pacific in the summer of 1861. The first war steamers were all paddle-wheel vessels, and this mode of propulsion brought a change in the armament, or rather in the method of mounting guns. The paddle-wheels being quite exposed, and the machinery also being possibly endangered by water-lining, there was greatest danger that a lucky shot would soon put a ship out of action, if compelled to fight broadside to broadside, as ships had been neccessom to do formerly. To obviate this danger as far as possible, the few guns these paddle-ships carried were mounted as pivot-guns, being put in their places by the paddle-frigates, which were then at the disposal of their officers. But it was the application of the screw as a means of propelling ships which has really revolutionised ships of war. Its vast superiority over the paddle was at once seen, and by the commencement of the Russian war in 1854 more than 1000 steamers and vessels had been either converted or built as screw ships. After the conclusion of the war many of the sailing three-deckers were converted into steam two-deckers, being lengthened amidships, and engines being then fitted to them; while during the American war, in the building of the new iron ships and vessels the armament seemed to have reached its acme, the line-of-battle ships and frigates which were launched at the time being quite unsurpassed for beauty of their hulls, their size, and their sailing and steaming qualities. Strangely enough, for the first time in that century, the French ships were far superior to the French, especially the line-of-battle ships, which all carried their lower deck guns twice as high out of the water as the French ships, and were altogether finer and
handsome models. But the knell of wooden ships had already sounded, and many of the finest

line-of-battle ships built at this time were never even commissioned.

To Napoleon III., emperor of the French, belongs the idea of plating ships with iron. The effect of shells on the ships at the first bombardment of Sebastopol showed clearly that unless some means of protection could be devised ships were placed at a terrible disadvantage when attacking heavy shore batteries. The result was the laying down in France and England in the year 1855 of what were called floating batteries, which were, however, completed too late to take any active part in the war. Some ten were built in England; they were 172 feet long, 43 feet beam, about 2500 tons displacement, a draught of water of 7 feet 9 inches, and had engines of 200 horse-power; they were plated with 4 inches of iron on 20 inches of wood backing; they could only steam about 5 knots, and, as they were flat-bottomed with no keels, were very unmanageable; but they were heavily armed, carrying sixteen 68-pounders in their batteries.

Three years later, however, the first ironclad frigate was laid down at Toulon, the celebrated La Gloire. She was designed by M. Dupuy-de-Lôme, head of the constructive department of the French admiralty, was built of wood and plated entirely with 4\(\frac{1}{2}\) inch iron plates to 6 feet below the water-line; she was 230 feet long, 55 feet beam, was built with a ram-bow, and could steam about 13.5 knots. She was launched in the early part of 1860, and in December of that year proceeded on a series of trials in company with the Algerceiras, one of the fastest French line-of-battle ships. She proved herself a good sea-boat, and under all conditions steamed better than the wooden ships. In England they were not idle, and in January 1861 the Warrior was launched from the works of the Thames Shipbuilding Company. Designed by Mr Scott Russell, this ship, which, unlike La Gloire, is still fit for service, was built entirely of iron. She is, however, only armoured for two-thirds of her length, her bow and stern being unprotected; she is 9210 tons, 420 feet over all, with a beam of 59 feet, and her plating 4\(\frac{1}{2}\) inches thick; while her engines—5700 indicated horse-power—gave her a speed of nearly 15 knots.

She was thus nearly double the size and tonnage of La Gloire; but, although still a fine vessel and a beautiful model, she has long been obsolete as a fighting ship. She was quickly followed by others—ships in which the armour was carried completely round the hull; and in order more rapidly to form a large ironclad fleet several of the new line-of-battle ships were cut down, and converted into armoured frigates with ram-bows, and with plating from 4\(\frac{1}{2}\) to 6 inches in thickness. These ships were, however, only makeshifts, as they had no watertight bulkheads, and the armour soon caused the wooden sides underneath to rot and decay. Still they answered their purpose, and filled a gap until newer and stronger ships, built entirely of iron, could be designed and constructed.

From 1861, when the Warrior was launched, up to the present day has been an unceasing era of change in design to meet the ever-increasing requirements of a modern ship of war, brought about by the production of guns ever growing in size and power, and the corresponding necessity of increased thickness of armour. In Hampton Roads during the American civil war was fought on the 9th of March 1862 the first naval action between armoured ships, which practically sealed the fate of armoured frigates of the earlier type almost before they had in many cases left the stocks. When Norfolk with its dockyard was evacuated by the Federal troops at the outbreak of the war between the Northern and Southern states, the Merrimac, a large 50-gun steam-frigate, was set on fire to prevent her falling into the hands of the Confederates. She was, however, only partly burned, and the Confederates found her in all essential respects uninjured. Remembering the many experiments that had been made in Europe to show the value of iron armour for ships, and painfully conscious of their weakness at sea, they appear to have thought there was one grand opportunity open to them, and to have made use of it with characteristic vigour and skill. They built up over her deck and down upon her sides to below the water-line a shot-proof covering formed of sloping plates of railroad iron, and meeting at the top like the roof of a house, through which came her funnel and the only opening for ventilation. She was armed with two 100-pounder Armstrong guns and eight 11-inch guns, and on the 8th of March 1862 she steamed out to attack the blockading Federal squadron, consisting of two

sailing frigates, the Cumberland and the Congress, and three steam-frigates, which latter, however, were unable to come up in time to take part in the action. The Cumberland was sunk and the Congress had to surrender, the Merrimac herself sustaining no injury, although she sunk the first-named ship by ramming. The next morning she came out to attack the remaining ships, but was met by an antagonist which, although much smaller, proved more than a match for her. This was the celebrated Monitor, built and designed by Captain Ericsson (q.v.); and from her have sprung the monster turret-ships of the present day. She was only 210 feet long, with an extreme beam of 45 feet; her deck and low sides were plated, and she carried two 150-pounder Dahlgren guns in a single turret amidships, which were protected with eight 1-inch iron plates screwed together, and was turned by steam; she had no bulwarks, and her deck was barely two feet out of the water, while besides the turret nothing showed on deck except her funnel and an armoured pilot-house at the stern. The result of the fight is well known, and the Merrimac had to retreat before her small opponent. Great was the excitement caused when the news of this action reached Europe, and nowhere more than in England, where a demand immediately arose for the conversion of the fleet into turret-ships. Captain Cowper Coles (q.v.) had ever since the Crimean war been urging the Admiralty to build turret-ships in some form or another, but no attention had been paid to him; he now again came forward with plans for converting some of the wooden ships into Monitors, and the Admiralty determined to give his plan a trial. Accordingly a screw three-decker, the Royal Sovereign, was cut down, armoured plated, and fitted with four turrets, each carrying two 9-ton guns. She had a freeboard of six feet, thus making her a great deal more seaworthy than the American Monitor; but, as the ship had not originally been destined for such heavy work, she laboured under some disadvantages. Nevertheless she was considered for a time the most formidable ship in the navy. When once fairly tried the advantages of the turret over the broadside system were evident; the turrets were placed in the centre of the ship, so the weight of the guns and the armour of the ship is more systematically and evenly distributed, and it has become possible to mount the heaviest guns in turrets and barbettes—guns of a size and weight which hitherto could not be carried on the broadside. Another advantage which turrets offer is the much greater protection afforded to the guns in them and to their crews, not only from the increased thickness of the armour which can be carried on them, but also from the probability that many projectiles will glance off the rounded surface of the turret instead of penetrating, while, owing to the low freeboard, the mark offered to an enemy is much smaller than in a high freeboard broadside ship.

Turret-ships did not, however, immediately supersede broadside ships, and the controversy as to the respective merits of the two systems raged for some time. Guns and armour were in the meantime growing. In 1866 the Betterton, a five-decker, was built, a fine broadside ship with a 6-inch belt at the water-line and 5-inch over her battery, in which she carried twelve 12-ton guns.

To Rear-Admiral Scott the country is indebted for the iron caricatures and slides, with their patent compressors for checking the recoil, which made the mounting of heavy guns on the broadside possible. But now a new danger to be guarded against had arisen in the shape of that dangerous weapon the torpedo. The word was first applied to everything, no matter what its nature, which was exploded under water against ships; but of late years the word torpedo refers solely to mobile under-water weapons of offence, and more particularly to the fish or Whitehead torpedo, whilst the fixed or stationary torpedoes are now called submarine mines (see Torpedoes and Mines). To afford as much protection as possible from these enemies, and also to make a ship as unsinkable as possible, not only has a system of building ships with an inner as well as an outer bottom been adopted, but by means of transverse and other bulkheads the space below the water-line is subdivided into a number of watertight compartments, so that if a ship is injured the damage and water admitted is confined to as small a section as possible. Two complete sets of engines, driving each a separate screw, also took the place of the old single screw. This not only gives ships greater turning powers, but if one engine is disabled they are not left quite helpless.

In 1869 three large low freeboard round-shoulder turret-ships were laid down, the Devastation, Thunderer, and Dreadnought; the first-named ship was commissioned at the end of 1872, and they have all done good service, and still remain amongst our most formidable ships. They are protected by a belt of 14-inch armour at the water-line; above this, running about two-thirds of the length of the ship, is an armoured deckwork with 12-inch armour which protects the base of the turrets, loading-gear, &c. An armoured deck resting on the top of the belt covers in the whole ship outside the casemate, the turrets being placed at each end of this breastwork. The freeboard fore and aft of these ships is extremely low, the deck being barely two feet above the water, thus neutralizing at sea the closing of all apertures by watertight hatches, as the deck is continually under water. A superstructure or hurricane deck is erected in the space between and slightly above the turrets, where
accommodation is found for the boats, chart-house, and armoured conning-tower; the funnels, ventilators, and means of communication with the interior of the ship when the hatches on the upper deck are closed, all lead up through this structure, which is sufficiently spacious to form a small promenade in bad weather. These ships and others of the same type are ventilated below by means of air which is driven down by fans worked by steam. They have only what is called a military mast, the principle use of which is to serve as a support for the derrick used to hoist out the large boats. The original armament of these ships consisted of four 35-ton muzzle-loading guns, but since 1890 they have been supplied with 29-ton breech-loading guns of the most modern type, and a full complement of 3- and 6-pounder quick-firing guns, which are mounted on the superstructure. The introduction of these types of sea-going turret-ships was a bold experiment and the occasion of much controversy; but even in the first venture a large measure of success was achieved. Deficiency of freeboard forward is the fault of the Devastation and her sisters, as also of many of the later ships, for with such a form of bow it is difficult, if not impracticable, to maintain a high rate of steering against a heavy sea. Of course, the object of the bows being kept so low is to offer a smaller target to the enemy and to enable the guns mounted in the fore-turret to command an all-round fire.

Captain Coles was not satisfied with the Royal Sovereign or the turret-ships subsequently designed. He believed he could build a turret-ships which, with a low freeboard, should yet be heavily manned and armed. As a result he designed, so the Captain, a large ship of over 6000 tons, was built from his designs with a freeboard of only 6 feet; she was heavily manned so as to give her great sail-power; her design was not approved at the Admiralty, her freeboard for a masteed-ship being considered dangerously low. So the Monarch, a turret-ship of almost the same tonnage, but with a freeboard of 14 feet, was built at the same time, embodying the Admiralty idea of what a masteed-ship ought to be. Both ships carried four 25-ton guns in their turrets. The fate of the unfortunate Captain is well known. About an hour after midnight on the morning of the 6th of September 1870, while cruising with the Channel Squadron off Cape Finisterre, she was capsized when under sail in a heavy squall, and went down immediately. 560 officers and men, among whom were her captain, Captain Burgoyne, V.C., and Captain Coles himself, were lost. The Monarch, on the other hand, has been continually in commission, and in 1890 was re-engined and provided with new breech-loading guns. After the conclusion of the Lumberphax in 1866 an entire change was made in the arrangement of the guns in the batteries and in the disposition of the armour-plating in the new broadside ships which followed her. The Batterophon, like her predecessors, was armoured all over, the plating extending some 5 feet below the water-line, while her guns extended along the maindeck as in the old wooden ships. An attempt was now to be made, without materially increasing the size of the ships, to carry yet heavier guns and protect them with thicker plating; at the same time various devices were resorted to to try and combine some of the advantages of the turret-ship with the broadside system of mounting guns, by giving an end-on fire to bow and quarter guns and generally increasing the arc of training.

The result was what are now known as central battery ships, of which the Hercules, Sultan, Téméraire, and Alexandra are very fine specimens. These ships have a complete belt of armour round the water-line tapering from 12 inches to 5 inches in thickness. The armour is carried up over the central portion of the ship and the batteries; athwartship armour bulkheads shut in the batteries fore and aft, forming a complete armoured citadel; before and abaft these bulkheads, above the armour-belt, the sides are unprotected in any way, and here are the quarters for the officers and men. The guns are carried in the batteries, there being an upper and a lower one, the lower being the main or principal battery; the foremost and after ports are recessed so as to give a nearly end-on fire, while in some cases the upper belt is made to overhang, the ship's side being made to fall in, and thus a direct bow and stern fire is obtained. Both the Alexandra and Téméraire carry 25-ton and 18-ton guns in their batteries; these ships were launched in 1875, and were the last broadside ships to be built, as they are the finest. After the loss of the Captain, and in view of the rapidity with which the Alexandra and other ships are being built with armour for the mastery, as illustrated by the fact that in ten years progress had been made from 43 to 14 inch armour, and from 68-pounders to 35-ton guns, the Admiralty appointed a committee of naval officers and architects to consider and report on the best design for the battle-ship of the future.

The result of their deliberations was the adoption of what is known as the citadel type of ship, and on this principle, with certain modifications, several battle-ships were built.

In this type of ship the continuous armour-belt round the water-line is done away with, and in its place the armour of great thickness is concentrated round a citadel in the central portion of the ship; the length of the citadel varies from about one-third the length of the ship to nearly a half; the armour extends from water-line to about 5 feet above it; at each extremity rise the turrets in which the guns are mounted. In the Inflexible, the first ship of this type built, the armour at the water-line is 24 inches thick, with 17 inches on the turrets; the plates, however, are of iron, while in the later ships they are compound—iron faced with steel. The Inflexible carries two 81-ton muzzle-loading guns in each of her turrets, capable of throwing a projectile of 1750 lb. weight a distance of 64 miles, with an initial velocity of 1800 feet. From the base of
the citadel fore and aft extends the whole remaining length of the ship a watertight turtle-backed armoured deck, from 2½ to 3 inches thick; and below this deck, which is below the water-line and within the citadel, are contained all the vital parts of the ship—engines, boilers, magazines, &c.—the only communication from above being down through the citadel. The quarters for the officers and men are mostly provided in those parts of the ship before and abaft the citadel, and are built up above the armoured deck; the idea being that these armoured ends might be destroyed by the enemy's fire, but that the body of the ship would remain intact; the citadel, in fact, resting on an unsinkable inner shell below the surface of the water, there being as many as two hundred different watertight compartments in one of the latest battleships, including the compartments of the double bottom.

Since the year 1880 another revolution has been carried out, this time in the armament of ships, steel breech-loading guns being now substituted for the old bronze loaders. This change was rendered necessary in order to obtain the increased velocity requisite to penetrate the thicker armour in use. It was found that the necessary length to obtain this increased velocity could not be given to guns which were loaded at the muzzle, so the authorities found themselves compelled to rearms our whole fleet anew. The work was long in completing, but since 1882 all the new battleships and cruisers have received the new guns. The introduction of fast-steaming torpedo boats has also rendered it necessary for the heavy armament of battleships to be supplemented by a large number of light guns; and to the necessity of meeting the attacks of these swift little vessels, we are indebted for all the rapid-firing guns now in use, of which every ship carries a large complement. It thus again became necessary to carry guns on the broadside, and the design of the citadel ships had to be materially modified. Six battleships were laid down, known as the Admiral class, instead of in turrets. These barbettes are carried at a considerable height above the armoured portion of the hull, and all the hydraulic loading arrangements are protected by them. The ammunition is also brought up from below through armoured tubes. A belt of 18 inches of compound armour protects about 156 feet of the water-line of the ship amidships, and there is in addition a 3-inch steel-armoured deck. Between the barbettes is a long central battery, in which are carried the ten 6-inch guns forming the auxiliary battery, while on the spar-deck above are mounted a due proportion of 3- and 6-pounder quick-firing guns. The advantages claimed for the barbette system, which is in general use by the French, over the turret, is that the guns are carried much higher out of the water; on the other hand, they are much more liable to injury from an enemy's fire, as, except when loading, the whole gun is completely exposed; while the absence of broadside armour for the central secondary battery is a serious defect, leaving the crews, as it does, exposed to destruction by shells charged with melanite or other high explosives, and the hail of fire from the quick-firing guns, which are also low forward, and, although fast ships, they cannot steam at any speed against a heavy head sea.

As the outcome of the popular revulsion against the Admiral type of battleship, in consequence of the small amount of armour-protection, and in view of the development of high explosives for use in shells, and the rapid growth in the size of the quick-firing guns, the Nile and Trafalgar were laid down in the year 1885. For their offensive powers and for

---

**Fig. 9.—Diagram showing Disposition of Armour and Armoured Deck in H.M.S. Colossus (1882), improved Indestructible type, twin-screw double-turret citadel battleship, 1st class, with unarmoured end but armoured deck. 9490 tons, 7500 h.p., four 47-ton guns, two in each turret; five 6-inch guns on superstructure.**

**Fig. 11.—Diagram showing Disposition of Armour in H.M.S. Trafalgar (1888), twin-screw double-turret battleship, 1st class, with armoured central battery. 11,940 tons, 12,000 h.p., four 67-ton guns in turret (a); eight 40-pounder quick-firing guns on spar-deck (c); fighting top with two 6-pd. q.f. guns (d).**

The completeness of their armour-protection, as compared with any former ships, they were unquestionably the two most formidable battle ships launched till then. Although not completely belted all round, they are very nearly so, and may be described as improved Dreadnoughts, with the addition of a central battery between the turrets for the auxiliary armament, in place of the superstructure of the earlier ships. The main armament consists of four 67-ton guns, while the auxiliary armament consists of eight 4·7-inch 40-pounder quick-firing guns, which are protected by 5-inch steel armour; and in addition they carry sixteen 3-pounder and 6-pounder quick-firing guns, mostly mounted on the spar-deck. In 1889 what is known as the Naval Defence Act was passed, which authorized the construction of ten new battleships, forty 1st and 2d class cruisers, and twenty torpedo gunboats. (Two of the new battleships were launched in 1892,) 14,000 tons displacement, have a length of 380 feet, and a beam of 75 feet; their engines of 13,000 horse-power have a speed of 18 knots, a knot faster than that of the Nile and Trafalgar. The disposition of the armament is much the same as in the two former ships, and the armour is of the same thickness except at the water-line, where it is two inches less; this water-line belt is
NAVY

84 feet broad, extending three-fourths the length of the ship, with a maximum thickness of 18 inches; the broadside also contains two reinforced armoured bulwarks; above it is a 3-inch steel deck, while a strong under-water deck completes the protection before and abaft the belt. The broadside above the belt is protected to a height of 94 feet above water over a considerable portion of the length by 5-inch armour, screen bulkheads similarly armoured enclosing the central battery. The armour on the barbettes is 17 inches thick, while the protection of the guns and crews of the auxiliary armament has been carefully arranged in view of the development of high explosives and quick-firing guns. In eight of these ships the main armament of 134-inch 67-ton guns is carried in barbettes 23 feet above the water; in the remaining two they are mounted in turrets. The auxiliary armament consists of ten 6-inch 5-ton 100-pounder quick-firing guns, sixteen 16-pounders, and eight 3-pounder quick-fires, together with seven torpedo-tubes, of which two are submerged.

Since 1880 a large number of fast cruisers have been built. Of these ten are protected by a belt of 10-inch steel armour two-thirds of the length of the ship at the waterline, as well as by an armoured deck; all the remainder are known as 'protected cruisers'—i.e. they have an armoured turtle-backed deck which extends throughout the length of the ship; the thickness varies in the different ships from 6 inches on the slope to 2 inches on the horizontal part. The top of the deck rises to a maximum of about 18 inches above the water-line, but on the side it curves down to join the plating of the skin 65 feet below the water. In the new cruisers, round the hatchways, funnel casings, &c., protection is given by 5-inch steel armour, while the guns above are protected by casemates plated with 4-inch steel armour, and the ammunition is passed up from the magazines to the guns through armoured tubes. The speed of these ships varies from about 16 knots in the cruisers of 1890 to 10 knots in the more recent ones, and two first-class cruisers, the Blake and Blenheim, were intended to steam 22 knots. As in the battle-ships, so in the modern cruisers.

Fig. 12.—Section of Turret, showing System of Mounting Heavy Guns, and Hydraulic Arrangement for Loading.—H.M.S. Colossus.

A, saddle on which the gun is fixed; B, recoil press; S, slide; C, pivot of slide; D, elevating cylinder; E, loading trough; F, rammer; G, hydraulic arrangement for working breech-block; H, ram for raising rammer and shot; L, teak backing; M, 18-inch armour; N, the gun (47-ton breech-loader). The projectile is placed in a trough (E) on the deck; the trough is raised by a ram (H) until it is in the required position (E) for loading; a rammer (F) then passing up the trough forces the projectile into the gun; on the tronch being lowered, the cartridge is placed in it and rammed home in a similar manner.

masts and sails have been done away with; and while the battle-ships have what is called a military mast fitted with two armoured tops in which are carried one or more quick-firing guns, the cruisers have only a couple of light poles for signalling purposes. The armament of the cruisers consists generally of two 9-inch 22-ton guns as bow-and-stern-chasers, and a proportion of 6-inch or 5-inch guns, according to the size of the ship, with a due complement of quick-firing guns and four or six tubes for discharging Whitehead torpedoes. In these ships which have no vertical armour a certain amount of protection is afforded by the stowage of coal in bunkers above the water-line. Battle-ships and cruisers alike are now lit by electricity, by means of which also the guns are fired and torpedoes discharged; they are also provided with powerful electric search-lights, which will illuminate the sea for some 2 miles, while night-signalling is now carried on also by electric light. As a further defence against torpedoes, all large ships are provided with torpedo-nets, which are made of steel wire, with meshes of about 3 inches in diameter, and are rigged out all round the ship by means of booms, which project about 30 feet from the ship's side a little above the water-line; these nets are about 18 feet deep, and when not required for use are stowed inboard.

Ships are further provided with countermines for the purpose of destroying mine-fields defending hostile harbours. See TORPEDOES, MINES.

In England iron plates faced with steel (called compound plates) have been definitively adopted for heavy armour; while steel plates, from 6 inches to 2 inches in thickness, are used for the armoured decks and the shields for the protection of the light guns; and steel steel, now used instead of iron for the hulls of all ships.

The heaviest guns in use in the royal navy are the 111-ton breech-loaders, which throw a projectile of 1800 Ib., with an initial velocity of 2300 feet, from 10 to 11 miles. The charge for this gun is 900 lb. of brown prismatic powder. These guns were put in three ships, the Victoria (lost in 1853) and Samarai, in these being mounted in pairs in a single turret forward, and the Lio e, which has one mounted in each of her barbettes forward and aft. The 67-ton gun proved most successful, and was in 1880 adopted as the heavy gun. The cost of the 110-ton gun is £19,600; of the 67-ton gun, £13,600; of the 22-ton gun, £416; while a 5-inch 36 cwt. gun costs £568.

In considering the question of guns it is essential to keep in view that the armoured dimensions as the calibre increases; the life of the 110-ton gun is considered to be 95 rounds; that of the 67-ton gun, 127 rounds; and that of the 45-ton gun, 150 rounds. The 67-ton gun throws a projectile of 1250 lb., with a charge of 630 lb. of brown prismatic powder, a distance of 10 miles, and will pierce 30 inches of armour; but experience shows that armour of this weight cannot be carried on ships of anything like a reasonable size. There is a strong opinion among naval officers that a 12-inch gun of modern design and about 50 tons in weight should possess sufficient power; and in 1885 the Majestic's 12-inch
46-ton gun showed energy little less than that of the 67-ton gun, and greater power of penetration than the 110-ton gun. In the smaller types of quick-firing guns the projectile and charge are made up in one cartridge, and by an ingenious arrangement of the breech it can be opened and closed by one man almost simultaneously. The first quick-firing guns were the 3-pounders and 6-pounders invented by Nordenfelt and Hotchkiss: these guns fired twenty-eight rounds a minute. A 40-pounder quick-firer, made at Elswick, proved most successful.

A 106-pounder gun was the next enterprise (see CASSEL'S MACHINE-GUN). The

The nine battleships of the Spencer programme—Majestic, Magnificent, Victorious, Prince George, Mars, Jupiter, Illustrious, Hannibal, and Caesar, launched 1896-97—were of 14,900 tons and the largest ships afloat except the Italian and Leopoldo. The first-class battle-ships,—Cavour (Cavour, Ocean, Goliat, Albion, Glory, Vengeance)—are of about 12,950 tons. The Renown is of 12,350. The Spartiate, launched 1898, is of 11,000 tons. The first-class cruisers Powerful and Terrible are ships of 14,000 tons. The garments launched in 1895-96 were the Implacable and the Inflexible; the former, launched 1896, was the largest of the three first-class battle-ships; she had a displacement of 18,960 tons. The latter was called 'Improved Majestic,' and the Majestic was itself called 'an improved Royal Sovereign.' The tonnage is 14,900, the engines are 15,000 horse-power, and there are twin screws; the ship's crew consists of 587. The port side of the armoured ship is armed with four 12-inch breechloading wire guns, twelve 6-inch quick-firers, each in its own casemate of Harveyed steel; sixteen 12-pounder quick-firers; two 12-pounder 8-cwt. guns; eight Maxim; four submerged torpedo-tubes; and a heavy steel armoured breast. The greater ships may be set down at or over £2,000,000.

In 1898 there were 30 battle-ships of the first class, 7 of the second, and 21 of the third; 14 coast defence ships; 9 armoured cruisers; 16 first-class cruisers; 64 second and third class cruisers; 19 ironclad ships; 44 torpedo gunboats; 147 first-class torpedo boats, 4 of the second class and 29 of the third. Besides, there were building 9 first-class battle-ships, 12 first-class cruisers, 2 sloops, 4 gunboats, and 41 torpedo destroyers. The new programme of 1898 comprised 3 battle-ships, 4 armoured cruisers and 4 sloops, besides 4 armoured cruisers ordered in July 1897.

The naval estimates proposed by Mr Goschen for 1898-99 amounted to £23,700,000, providing for a force of 106,000 men and boys of all ranks.

As compared with the French navy, next in size, Britain, 1898, in battle-ships 53 to their 32; in armoured cruisers 18 to their 9; protected cruisers 109 to 36; in unprotected cruisers 16 to 16; in coast defence ships 15 to 14; in torpedo craft 214 to the French 225. The general contention is that Britain must keep her navy strong enough to meet any two of the others. The great naval review at Spithead in the Jubilee year, 1897, attracted notice to the unparalleled strength of the British navy. And after the German Emperor's letter to President Kruger in 1896, and during the Fashoda incident in 1898, the weight of the navy obviously influenced the scales of diplomacy. The year of the Czar's peace manifesto (1894) saw the utter destruction of the Spanish navy by that of the United States, a still more convincing proof of the importance of a large and powerful navy than the destruction of the French fleet by the 38 ships of 1894; and Britain, France, Germany, and Russia were all increasing their naval strength.

In 1861, just before the introduction of ironclads, the flagship in the Mediterranean was the screw three-decker Marlborough, of 121 guns, and with a crew of 1290 officers and men. The officers and crew of a line-of-battle ship averaged as a rule from 800 to 950; of a frigate, from 400 to 600; and smaller ships in proportion. A modern battle-ships of the Colossus type has a complement of 450 officers and men; a barbette ship of the Rodney class, one of 780, of whom 360 are officers and men; and a monitor type, one of 750. The Formidable (1898), if used as flag-ship, has a complement of 789 officers and men. In a battle ship, with a complement of 600 officers and men, the numbers and ratings would be approximately as follows: the vice-admiral and his staff, consisting of his flag-lying Gulf of St. Vincent, and 4 secretaries' clerks, and 7 petty officers, 4 carpenters, 4 seamen, and 28 ratings; the first-class flag-ship, 24 petty officers, 12 seamen, and 28 ratings; the second-class flag-ship, six petty officers, four seamen, and 28 ratings; and the third-class flag-ship, three petty officers, two seamen, and 28 ratings. The ship's company would be composed of about 40 chief, 1st and 2d class petty officers and leading seamen, 260 seamen and boys, 90 marines, 15 engine-room artificers, and 120 stokers, the remainder bandsmen and other non-combatants. Not only are the complement of officers increased, but the proportion of men is increased in the old ships, but the proportion of trained seamen is also much smaller in comparison with the rest of the crew. This is due to the increase of the engine-room staffs, and to the large number of stokers now carried in the new ships, amounting sometimes to as many as 300. But the officers must be trained as machine men. As this large number of untrained men seriously affects the fighting efficiency of ships, steps are now taken to minimise the danger by training the stokers regularly at heavy gun and other drill, so that those not actually required in the stokeholds may be available for use as combatants in action. Foreign men-of-war are far more heavily manned than English ships of a similar size. By the Naval Defence Act of 1889, and in the estimates of 1898, provision was made to carry into effect a large increase of the personnel of the navy.

See Derrick, The British Navy (1896); W. Jance, Naval History of Great Britins (2d ed. 5 vols. 1847); King, Navies of the World (1880); Lord Brassey, The British Navy (5 vols. 1882-85), and his Naval Annual; G. T. Mahan, Influence of the Sea Power (1882); several works by J. W. Glen (3d ed. 1878); Wilkens, The Wars (1879); Luke, The British Navy (1893); H. H. Wilson, Ironclads in Action (1895); Robinson, The British Fleet (new ed. 1896); Steevens, Naval Policy (1896); W. L. Clayes and others, The British Navy (3 vols. 1895); Hutton, Naval Pocket-Book by Clayes. For the Royal Naval College, see GREENWICH; see also TRAINING-SHIPS, TACTICS, CADET, MARINES, NAVAL RESERVE, TORPEDO, GUNS, &c., &c., &c.; those on the great naval commanders, BLAKE, NELSON, &c.; and the sections of the articles on the various countries—France, Germany, Italy, &c., &c., dealing with national defence.

NAVY AGENT, a banker and attorney for naval officers, who bears some such relation to Admiralty expenditure as the Army Agent (q.v.) to War Office expenditure. By the Act of 1865, each of Her Majesty's ships of war, while in commission, has an agent appointed by the Admiralty, or any other person. His duties are to act for the ship in cases of salvage, merchant shipping law, distribution of prize-money, capture of slave-ships, &c. He receives 2½ per cent. as payment in full of his services. See the Navy List.

Nawana Kar. A seaport of India, and capital of a native state (area, 1580 sq. m. ; pop. 320,000), stands on the north shore of the Gulf of Cambay, 310 miles N.W. of Bombay. Pop. (1891) 48,530.

Naworth Castle. See LANCASTER.

Naxos. The largest, most beautiful, and most fertile of the Cyclades, is situated in the Aegean, midway between the coasts of Greece and Asia.
NAZARENES

Minor. It is 20 miles in length, and has a pop. of 14,880. The shores are steep, and the island is traversed by a ridge of mountains, which rise in the interior to 3289 feet. The wine of Naxos was famous in ancient as it is in modern times, and on this account the island was celebrated in the legends of Dionysus, and especially in those relating to Ariadne (q.v.). It was ravaged by the Persians, 490 B.C., and again in the conquest of Constantinople by the Latins, became the seat of a dukedom founded by the Venetians. It was Turkish from 1560 till Greece became a kingdom. Naxos, the capital (pop. 2000), is the seat of a Greek bishop and a Latin archbishop. See Tozer's Islands of the Aegean (1890).

Nazarenes. See ERIONITES.

Nazareth, the home of Jesus, anciently in the district of Galilee, 21 miles N.E. of Acre, is still a small but flourishing and orphanastige. It lies in a hilly tract of country, and is built partly on the sides of some rocky ridges. In the earliest ages of Christianity Nazareth (which is not mentioned in the Old Testament) was quite overlooked by the church; the first mention of it took place in the 8th century. The principal building is the Latin convent, on the supposed scene of the Annunciation; but the Greeks have also erected on another spot a church in commemoration. The traveller is also shown a Latin chapel, affirmed to be built over the 'workshop of Joseph;' the chapel of 'the Table of Christ' (Menae Christi), a vaulted chamber, containing the veritable table at which our Lord and his disciples ate; and the synagogue out of which he was thrust by his townsman. The Virgin's Well is just outside the town. The women of the village have been famous for their beauty. Major Conder says they are more Italian than Arab in feature—owing possibly to admixture of European blood. Pop. (1891) 7500 (2870 Greek Catholics, 1310 Roman Catholics, 650 United Greeks, 1825 Mohammedans). There is here a Prot. but flourishing orphanage.

Nazarites (properly Nasiaites, from Heb. nasisar, 'to separate'), men or women among the Jews who had consecrated themselves to God by certain acts of abstinence, as refraining from using wine, from shaving their heads, as well as from the defilement of contact with the dead. The law is laid down in the Book of Numbers (vi. 1-21). The usual term of the vow was thirty days, but examples of vows for life were the cases of Samson, Samuel, and John the Baptist.

Nazianzen. See GREGORY.

Negh, LOUGH, the largest lake of the British Islands, is situated in the province of Ulster, Ireland, and is surrounded by the counties of Armagh, Tyrone, Londonderry, Antrim, and Down. It is 16 miles in length and 10 miles in average breadth, contains 98,255 acres, is 102 feet in greatest depth, and is 48 feet above sea-level. It receives the waters of numerous streams, of which the principal are the Upper Bann, the Blackwater, and the Cally; and its surplus waters are carried off northward to the North Channel by the Lower Bann. Communication by means of canals subsists between the Lough and Belfast, Newry, and the Tyron coalfield. The southern shores of the Lough are hilly, marshy, and dreary in appearance. It is well stocked with trout and lough pike.

Neal, DANIEL, author of the History of the Puritans, was born in London, December 14, 1678. He was educated first at Merchant Taylors' School, and afterwards at Utrecht and Leyden, and in 1706 became minister of an Independent congregation in Aldersgate Street, London. His first work was a History of the New England (1729), which met with a very favourable reception in America. But his reputation rests on his laborious and accurate History of the Puritans (3 vols. 1752-55; new ed., with Life by Joseph Toulmin, Bath, 1758). Neal died at Bath, April 4, 1743.

Neal, JOHN, American author, was born at Falmouth (now Portland, Maine), August 25, 1793. In his youth he was a Quaker, and he began the world at twelve as a shop-boy. In 1818 he failed in business, and turned to the study of law, supporting himself the while by his pen. He was one of the first Americans to write in the greater English magazines, and from 1823 till 1827 he lived in England, part of the time as one of Bentham's students and secretaries. After his return to America he settled in his native town, practised law, edited newspapers, lectured, and found relaxation in practising and teaching boxing, fencing, and gymnastics. He died 21st June 1876. Among his numerous works are a series of novels, Bentham's Morals and Legislation, and Wandering Recollections of a Somewhat Busy Life (1869).

Neale, JOHN MASON, hymnologist, born in London, June 23, 1818, was educated at Trinity College, Cambridge, became incumbent of Crawley, Sussex, in 1842, and in May 1846 warden of Sackville College, East Grinstead, where he died, August 6, 1866. He belonged to the most advanced section of the High Church party, and was long a member of the House of Convocation. He was one of the revisers of the New Testament, and is shown as an able translator in England. He was inhibited by his bishop for fourteen years, and burned in effigy in 1857, while throughout his life his means were of the smallest. He founded in 1854 the well-known sisterhood of the Sacred Heart. His most important work is his History of the Holy Eastern Church (3 vols. 1846-51); others are Medieval Preachers (1857), History of the so-called 'Jansenist' Church of Holland (1858), a posthumous adaptation of The Pilgrims' Progress (1853), and a long series of studies for the young, intended to popularise church history, but the value of which is almost exclusively other than historical. But his greatest work was his invaluable contribution to hymnology, both original and translated. His Hymns for the Sick and Hymns for Children were followed by his more important volumes of Hymns for Young Children: Hymns and Tunes (1851), the Rhythm of Bernard of Morlaix (1858), and his Hymns of the Eastern Church (1863). Many of his translations are cherished by all English-speaking Christendom, as the beautiful hymns, 'O love how deep, how broad,' 'The day is past and over,' and the exquisite series adapted from his translation of Bernard of Morlaix's poem, 'The world is very evil,' 'Brief life is here our portion,' 'For thee, O dear, dear country,' and 'Jerusalem the golden. There is no modern author to whom hymnology owes a greater debt than to this one inspired writer whose own conscious ecclesiastical sympathies were yet so narrow. A selection from his writings appeared in 1884. See HYMN.

Neander, JOHANN AUGUST WILHELM, the greatest of church historians, was born at Göttingen, 17th January 1789, of Jewish parentage. His name prior to baptism was David Mendel, and by the mother's side he was related to the philosopher Mendelssohn. He received his early education at the Johanneum in Hamburg, and had for companions Varnhagen von Ense and Chamisso the poet. Even while he was a boy, Plato and Plutarch were his familiar study books. By the age of 20 he was stirred by Schleiermacher's famous Rufen über die Religion (1799). Finally in 1806 he publicly denounced Judaism, and was baptised, adopting the name of Neander ('new man'), and taking his Christian names from several of his friends. His sisters and brothers, and later his mother also,
NEANDERTHAL

followed his example. He now proceeded to Halle, where he studied theology under Schleiermacher, and concluded his academic course at Göttingen. In 1811 he took up his residence at Heidelberg as a privatdozent; in 1812 he was appointed there extra-ordinary professor of Theology; and in 1818 he became extraordinary to the newly established university of Berlin as professor of Church History. Here he laboured till his death, July 14, 1850. Students flocked to him not only from all parts of Germany, but from the most distant Protestant countries. And his sweetness of character, his attractiveness in his general Profoundly devotional, sympathetic, glad-hearted, profusely benevolent, and without a shadow of selfishness, he inspired universal reverence, and was himself by the simplicity and sanctity of his life the greatest supply of historical Christianity than even his writings. He used to give the poorer students free admission to his lectures, and to supply them with clothes and money. The greater portion of what he made by his books he bestowed upon missionary, Bible, and music societies, and upon holy

Neander is believed to have contributed more than any other single Christian scholar to the overthrow, on the one side, of that anti-historical Rationalism, and on the other of that dead Lutheran formalism, from both of which the religious life of Germany has been so long separated. To the elaboration of the development of historical Christianity he brought a generous and sympathetic, yet broad and impartial intellect. To him Christianity was a per- ceasing force more than a series of dogmas, and the history of the church was throughout by the his- tory of the divine life of Christ pervading humanity, to be understood only in proportion to the student's personal experience of the significance of the life of Christ. This is the meaning of Neander's famous aphorism—'Poeaut est quod factum theologum.' The most striking characteristic of his great work is its objectivity in the portrayal of persons and the movement of events; its greatest merit is the admirable biographical skill with which the figures are made to pass before the reader; its one defect, the weakness with which the outstanding separate forms are fitted into their relation to the general movement of events.

Neander's works, in the order of time, are monographs on Julian and his times (1812), St. Bernard (1813), the Gnostics (1818), St. Chrysostom (1822); Denkwürd- ligkeiten (1824); Geschichte der christlichen Lebens (1822; 3d ed. 1845-46); Antiquistes (1836); the great Allgemeine Geschichte der Christlichen Religion und Kirche (6 vols. 1825-32); Geschichte der Pfalzung und Leitung der Kirche durch die legend (2 vols. 1833; 4th ed. 1847); Das Leben Jesu Christi, written as a reply to Strauss's work (1837; 5th ed. 1851); Wissenschaftliche Abhandlungen (1851); Geschichte der christlichen Doxen (1859). Most of these works are accessible in good English translations. See the studies by Hagenbach (1851), Otto Knaube (1852), J. L. Jacoby (1882), and Adelbert Weigand, the last with a good bibli- ography appended (1889).

Neanderthal, a wibly romantic valley between Düsseldorf and Elberfeld in Rheinland Prusse. In a limestone cave in this valley was found in 1857 the skeleton of a prehistoric man, and the peculiar formation of the skull induced several archaeologists to regard it as typical of a separate race of ancient cave-dwellers. Other authorities explain the anomaly as caused by disease during the lifetime of the individual.

Neap-tides. See TIDES.

Nearcis, an officer of Alexander the Great, was a native of Crete, who settled in Amphipolis during the reign of Philip, and became the companion and friend of the young prince Alexander.

In 330 B.C. he was governor of Lycaon and other provinces in Asia Minor. In 329 B.C. he joined Alexander in Bactria with a body of Greek mercenaries, and took part in the Indian campaigns. Having built a fleet on the Hydaspes, Alexander gave Nearcis the command of it. He left the Indies towards the end of November 323 B.C., and skirting the coast all the way, arrived at Susa, in Persia, in February 324. His own narrative of his voyage has been preserved in the Indica of Arrian, the best edition of which is printed in C. Müller's Geographi Græci Minores (Paris, 1853).

NEBRASKA

NEBRASKA, a central state of the American Union, and the eleventh in area, lies between 40° and 43° N. lat., and in 95° 29' W. long. Copyright 1891, 1897, and 1901 in the U.S. by J. B. Lippincott Company. Published by South Dakota, Iowa (sepa- rated by the Missouri River), Kansas, Colorado, and Wyoming. Area, 76,855 sq. mi., of which one-fifth is in improved farms. The surface is chiefly an elevated, undulating prairie; it is very level in the eastern and southern portions, but in the north and west the 'Bad Lands' extend into the state. southeast of the Missouri, the Niobrara River there are great sandhills composed of pebbles, gravel, and sand, covered for the most part with a sparse vegetation. The average elevation of the state rises from about 1200 feet in the east to 6000 feet towards the western border. The principal rivers are the Platte, the Niobrara, the Loup, the Republican, all flowing east. The atmosphere is dry and invigorating, and, though great extremes of heat and cold are sometimes experienced, they are not usual. There are few swamps and marshes. The average rainfall in 1889 was 21.83 inches; the mean temperature 51° 29' (range from 94° above to 17° below zero). Buffalo and antelope are still, though seldom, seen; but the coyote, large timber wolf, fox, skunk, rabbits, etc. abound. The soil of Nebraska, except in the Bad Lands and sandhills, is mostly a rich black mould, 2 to 4 feet in depth. The staple crop is maize, of which enormous quantities are grown. Tobacco and the sugar-beet also are cultivated successfully; of the latter the first very large crop was raised in 1890, but now there are a number of factories established for the manufacture of sugar; other important crops are wheat, rye, barley, flax, potatoes, and buckwheat. In the western part of the state the droughts are hurtful; there flowing wells are rare, and irrigation is needed. Forests are no- where found, and tree-planting has been extensively practised. The native productions are great quantities of hay, and Nebraska holds a good place among the stock-raising states; sheep, horses, and mules are raised, cattle in the western
nplands, and hogs in the east. The live-stock trade has its headquarters in Omaha, which in this respect ranks after Chicago and Kansas City.

Mineral products are not less important than agriculture. Limestone, sandstone, and coal are found; the latter has been mined for local use. In the eastern and northern parts are numerous factories. The articles produced include agricultural implements, vitrified brick for paving, washed clothing, soap, and the best-surfaced adobe referred to; while in a dozen towns canning factories are in operation. The ever-changing current and dangerous sand-bars of the Missouri do not encourage commercial intercourse by river; but the trade by rail (55 miles) is very heavy. Omaha and Lincoln are ports of entry.

Nebraska has forty universities, colleges, and academies; and the public schools (6234 in 1891-92, with 253,990 pupils in attendance, and 9085 teachers) are liberally provided for. The state and private charitable institutions also are numerous. The total expenditure for educational work in 1891-92 was $4,434,228. The assessed valuation of the state was $167,810,764.70 in 1898, being over $27,000,000 less than in 1892. Pop. (1890) 28,841; (1880) 432,492; (1890) 1,058,910; (1900) 1,066,300. The total population of the state is 1,081,559 in 1890. Lincoln, the capital (49,169), and South Omaha (28,001).

History.—Nebraska was included in the Louisiana Purchase, and was for many years a part of the North-west Territory. The way was prepared for settlers by the overland emigration to California in 1849. Nebraska territory was organized in 1854, with an area of 351,558 sq. m.; it extended north to British America, and west to the Rocky Mountains. But of this vast area great portions were afterwards ceded for Colorado, Montana, and Idaho. Nebraska became a state in 1867.

Nebraska City, capital of Otoe county, Nebraska, is on the west bank of the Missouri River, 74 miles below Omaha (44 by rail). It contains the Nebraska College (Episcopal, 1863), the Academy of Amunuation, an elevator, and a number of manufactories (1890) 7380.

Nebraska River. See PLATTE.

Nebuchadnezzar. See BABYLONIA, I. 634.

Nebiir: are closely patches of light in the heavens. Some, as those in Andromeda and Orion, are visible to the naked eye, but the greater number can only be seen in telescopes of considerable power. Before the invention of the Spectroscope (q.v.) there were for a time all considered to be star-clusters. This instrument has shown that these clusters, which appear as nebula in small telescopes, are totally different in constitution from nebula proper (see STARS). Halley in 1716 gave a small list of 6 nebula, but the chief workers in this field are Messier, who in 1784 catalogued 103; Sir W. Herschel, who alone discovered more than 2500; and Sir J. Herschel, who added to them more than 2000. These lists, however, include many star-clusters. Nebula proper have been classified as (1) annular, (2) elliptic, (3) spiral, (4) planetary, and (5) nebula. stars. These various forms do not indicate specific differences, but rather result from (1) the various presentation of their edges and surfaces to the spectator, and (2) their differently condensed material. For example, the elliptic nebula in Andromeda has been shown by photography to consist of a spiral in a cone of spiral, exhibiting thus in itself the marks of the first three classes. Planetary nebula show faint discs, often bluish in colour, whose structureless appearance is probably only due to our imperfect telescopes. The spectrum of nebula consists usually of a few bright lines indicating their gaseous structure. To what gases these lines belong is still uncertain, although they have been attributed to nitrogen, hydrogen, and magnetism in paper. In a few cases, as in a small nebula in Taurus and the gaseous spiral of Orion, the light certainly varies in intensity, and they are sometimes associated with variable or temporary stars. They form, according to the theory of Laplace and Sir W. Herschel, the earliest stage in the formation of stars and planets. Though certainly not yet proved, this nebular theory is very generally accepted, and has been greatly strengthened by Lockyer's recent spectroscopic researches.

Necessaries. See INFANT.

Necessity may be natural, according to the laws of nature; logical or mathematical, according to the laws of human intelligence; moral, according to moral law. See CAUSALITY, LOGIC, ETHICS, KANT, EMPERICISM. Necessity, Necessitarianism, or Necessarianism, is also a name for the view that denies the freedom of the will. See WILL.

Neches River rises in eastern Texas, and flows about 350 miles SSE. to Sabine Lake, its waters passing thence by Sabine Pass into the Gulf of Mexico.

Neck. See SPINAL COLUMN, THROAT.—Of diseases of the neck, STIFF-NECK is the term commonly applied to the condition of the neck in which lateral movement of the head causes great pain, and which is due to rheumatism of the muscles lying on the side of the neck, especially the sternoclidus. In the great majority of cases only one side of the neck is affected, the head being drawn more or less obliquely towards that side; but occasionally both sides are equally attacked, in which case the head is kept stiffly erect and looking straight forwards. As long as the head is allowed to remain at rest there is merely a feeling of discomfort, but when the head is moved, there is a painful. This affection is usually caused either by exposure of the part affected to a current of cold air, or by wearing wet or damp clothes round the neck (see RHEUMATISM).—Derbyshire Neck is a synonym for Goutte (q.v.).—For Necks in geology, see FOSSEJOUS ROCK.

Neckar, one of the largest tributaries of the Rhine, and the principal river of Württemberg, rises on the eastern declivity of the Black Forest, near the village of Schweningen. It has a winding course of 250 miles, and joins the Rhine at Mannheim—the other towns on its banks being Tubingen, Heilbronn, and Heidelberg. In the neck of the state, about midway in its course, the Neckar is navigable. Fair wines are grown on its banks.

Necker, Jacques, a famous financier and minister of France, was born 30th September 1732, at Geneva, where his father, a native of Klastrin in Pomerania, had become professor of Public Law. At fifteen he went to Paris as a clerk to the banker Vernet, and in 1762 established the famous London and Paris bank of Thellinsou and Necker. His public career commenced with his becoming a syndic of the French East India Company, as well as minister for the republic of Geneva at Paris, and with his marriage (1764) to the charming, accomplished, and ambitious Suzanne Curchod, who was born in 1737, the daughter of a pastor near Lausanne, and who had lived Gobine for five years with a constancy of which his colder temper was not worthy. The rich banker had first wooed Madame de Vermenon, a wealthy widow, who, perceiving his lack of nobility, but that easily transferred his affections to her young protégé, and he proved till death an affectionate and faithful husband. She was religious and above reproach in character, yet her adm became a centre of all the intellect of Paris, and her Fridays drew together such celebrities.
NECKER

Necromancy, an ancient mode of divination by conjuring up the spirits of the dead to give answers to questions of the future. A classical example is the Old Testament story of the witch of Endor. The eleventh book of Homer’s Odyssey bears the title of Neckeromanteia and, in it, the shade of Tiresias is brought up and consulted by Ulysses. In most parts of Greece necromancy was practised by priests or consecrated persons in the temples; in Thessaly it was the profession of a distinct class of persons called Psychagogoi. See DIVINATION, and MAGIC.

Necklace, DIAMOND. See DIAMOND NECK-LACE.

Necker, as Grimm, Didierot, the aged Buffon, Marmontel, Thomas, D’Alembert, and the Abbé Galland. In 1773 Necker gained the prize of the French Academy for an Essay on Charles XII, and in 1774 he distinguished himself still further by his Essai sur le Commerce des Grains, in answer to the free-trade policy of the great Turgot, in which he claims for the state the right of fixing the price of grain and, if necessary, of prohibiting its exportation. Already also he had led the French ministry under the king and without him in 1776, Protestant as he was, he was made Director of the Treasury and next year Director-general of Finance. He devoted five years of hard work to his hopeless task, and showed he gave no statesmanlike forethought, but his term itself at last proved his dismissal, and Napoleon. Indeed, some of his revenue dial measures were a real boon to suffering France, as his more equitable adjustment of taxes, his establishment of state-guaranteed annuities and monts de piété. But his most ambitious scheme—the establishment of provincial assemblies over all France, one of the functions of which should be the apportionment of taxes, proved a disastrous failure. His retrenchments were hateful to the queen, and the publication in 1781 of his famous Compte Rendu, a plain statement of the financial state of France, was occasioned for his dismissal. He retired to Geneva, carrying with him the respect of all Frenchmen; and here he busied himself with writing, and married his only daughter in 1786 to the Swedish Baron von Stäell-Holstein. In 1787 he returned to Paris, and when M. Calonne at the opening of the Assembly of Notables in that year cast a doubt on the truth of the Compte Rendu, he published a justificatory minute, which drew upon him the king’s displeasure and his banishment to a distance of forty leagues from Paris. He was recalled to his former office in September 1788, and quickly made himself the popular hero of the hour by recommending the summons of the States-general. But the successful banker was infatuated with his popularity, and quickly proved himself unfit to steer the ship of state amid the storms of revolution, while his constitutional irresolution in the hour of danger drew the well-meaning king into the fatal error of being forced into recognizing the union of the three estates, instead of taking the lead in freely granting what was inevitable. On the 11th July, while sitting at dinner, he received the fatal wound which ended his life, but the fall of the Bastille three days later frightened the king into recalling him amid the wildest popular enthusiasm. But now his incompetence for greater matters than accounts was at length fully discovered, and after with fatal obstinacy spinning the help of Lafayette and Mirabeau, and leading the king to surrender his suspensive veto and the Assembly to stultify itself by a self-denying ordinance that ministers should not be chosen from its members, which made a really responsible parliamentary government in France impossible, he finally laid down his office, and the king regretted resigning early in the running of Mirabeau’s scheme for relieving immediate financial distress by the issue of assignats, September 1790. He retired to his estate of Coppel near Geneva, and here his wife died in 1791. He died himself, after publishing books which had no longer any importance, followed her on 9th April 1804.

The only other works that need be named are De l’Administration des Finances de la France (3 vols. 1784), Sur l’Administration de M. Necker, par lui-même (1791), Du Pouvoir exécutif dans les Grands États (2 vols. 1775-8), D’Value de son État, etc. (last edit. 2 vols. 1797), and Dernières Vues de Politique de France (1802). A collected edition was edited by his grandson (15 vols. 1820-21). See also the Memoirs of M. Necker, published by his daughter in 1804; and for his life, her work, La Vie privée de M. Necker (1804), and his grandson’s Notice sur la Vie de M. Necker, prefixed to the collected edition of his works. Five volumes of Mélanges from his wife’s journals and papers were printed (1788-1802). The story of his life was again summarized from the papers of his son, M. de Coppet, in the Comte D’Haussonville’s work, Le Salon de Madame Necker (2 vols. 1882; Eng. trans. 1882).

Necrotic, relating to a condition of necrosis, or death of tissue. Necrosis is a term employed to denote the death or mortification of bone, but often restricted to the cases in which a considerable part of the shaft of a long bone dies, either directly from injury or from violent inflammation, and is enclosed by a layer of new bone; the death of a thin superficial layer which is not enclosed in a shell of new bone being usually termed sequestration, and the more gradual destruction of cancellous tissue by a process of the name of Ewing. The bones of the iliac crest and the ilium and ischium are those which are most frequently affected by necrosis, but any bone may be the seat of the process. The jawbones, however, very often suffer from it in persons engaged in making Lucifer matches, the disease being induced by the pernicious action of the vapours of phosphorus. The general use of red or amorphous phosphorus for this purpose has rendered necrosis of the jaws much less common. The dead bone, known as the sequestrum, presents a rough appearance, as if worm-eaten. If the membrane investing the bone (the periosteum) remain healthy, it deposits lymph, which specially ossifies, forming a shell of healthy bone, which completely invests the dead portion. The essential point in the treatment is the removal of the sequestrum, which is too purely a surgical operation to be described in these pages.

Nectar, the name given by Homer, Hesiod, Pindar, and the Greek poets generally, and by the Romans, to the beverage of the gods. Their food being called Ambrosia (q.v.). But Sappho and Alcaeus make nectar the food of the gods and ambrosia their drink. Homer describes nectar as resembling red wine, and represents its continued use as causing immortality; and the ancient manufacturers of nectar and ambrosia are represented as of most delicious odour; and sprinkling with nectar, or anointing with ambrosia, is spoken of as conferring perpetual youth, and they are assumed as the symbol of everything most delightful to the taste.

Nectare, in Botany, an organ in the flowers of many plants, the numerous pores of which are devoted either to the secretion or the reception of honey. Of the former kind are nectariferous glands, scales, and pores; of the latter, tubes, cavities, &c.
needles. See fire, vol. iv, p. 630.

needle-gun. See breech-loading, rifles.

needles. The sewing-needle must be one of the oldest implements used by man. Bone needles with eyes are found in the reindeer-caves of France, and among the finds on the sites of the prehistoric lake-dwellings of central Europe there are numerous 'eye'd needles of bone and of bronze, but as yet only a single one of iron appears to have been discovered. Ancient bronze needles, 3 feet long, have been found in Egypt, and there are surgeon's needles and thimbles which have been used in sewing with ordinary needles from Pompeii in the Naples museum. Savage races use needles of various materials, such as bone, ivory, wood, and metal. Some tribes do their sewing with awls of bone or of thorns with which they make holes, and then by pushing and pulling work the thread or string through them in the same manner as a shoemaker does. The Fuegians in sewing skins even make a tie at every hole. The Kallirs make needles of iron or steel, with a constriction under the pin-like head, round which the end of the thread is tied instead of being passed through an eye.

Steel needles were made in 1370 at Nuremberg, at which early time its artisans were skilled in working and filing the drawing of wire in iron, steel, and brass. Previous to 1563 the wire used for making needles in England was imported from Spain and Germany, but in England the manufacture was not of much importance till about 1650. The early-made needles were all square-eyed. The seat of the needle-manufacture in Great Britain is at Redditch near Birmingham, where in the best factories considerable improvements have in recent years been effected by the adoption of new mechanical appliances, and especially of automatic machines in some of the processes.

In the system of processes, about twenty-two in number, by which needles are now made, the first is the cutting of the coils of wire into two-needle lengths by a guillotine shearing-machine. The wire is of the best crucible steel, and requires to be very carefully gauged to size. After being cut, the lengths are heated in a red heat and placed in loose bundles inside iron rings to be straightened by rolling each bundle backwards and forwards on a face plate with a slightly curved bar, through which the rings project (see fig. 1). The wires are next pointed at both ends, which was formerly entirely done by hand on a grindstone with a concave surface. An arrangement is now in use by which the wires are withdrawn—one closely following another—from a hopper by a pulley revolving at right angles to the grindstone, the wires being here giving length of the wires to the puller-band. In their passage between the pulley and the grindstone the wires (double-needle blanks) revolve on their axes and become pointed at one end, and the process is repeated for the pointing at the other end. The fine steel dust resulting from an injury to the health of the hand-grinders has for some years been drawn away from the operative by the suction of a strong current of air. The stamping of these two-length blanks in the middle by the hand-worked stamping-machine so as to produce the flat of the eyes and the mark for the holes (fig. 2), as well as the punching of the holes by a screw press, can now be accomplished by more expeditious machines.

by the newer method the wire blanks are automatically fed into a quick-running belt-driven machine, in which a punch and dies form the prints or flats for the eyes. The next operation consists in punching two oval holes through the two prints of each blank by a vertical belt-driven punching-machine. After being eyed the still double-blanks—they are now rather double needles joined at the heads by thin fins—are spitted through their eyes on two wires flatted at one end to retain them. The burr made by the punch and die (stamping) is now removed by filing the spitted needles on both sides, and after being broken in two between the heads, which are then also smoothed by filing, a row of single needles is left on each spit, as shown in fig. 3.

In the tempering process which the needles undergo at this stage, they are first hardened by being laid on a plate and raised to a red heat in a furnace, after which they are dipped in cold oil, kept cool by running off a portion as it gets warm and replacing it by an equal quantity of cold oil. The needles being now hard and easily broken, are made less brittle by placing them on a continuous band of wire gauze which travels slowly over gas flames. The next step is to roll the needles one by one under the finger on a smooth stone, and thus to break them out to give them the best feel. In parcels of 50,000 they are next washed and scoured with soap to remove any of the oil used in tempering which still adheres, and the eyes are afterwards 'blue'd to soften them. In the case of needles of fine quality the eyes are gilt. By one method the eyes are polished by brushing them loosely on wires carried by standards fixed to a tray or platform which is moved rapidly with a reciprocating motion in a horizontal plane. In about one hour, with the assistance of a little fine emery and oil, the constant swinging of the needles on the wire smooths their eyes so as not to cut the thread. But the eyes of the best needles are hand-polished with fine emery on flax threads. The next step is to grind the heads and set the points by hand on a rapidly-revolving stone of fine texture.

An inging-machine is employed for the final polishing of the shanks. The needles are fed in a longitudinal direction, in rows one deep, between transverse leather-covered rollers, with holding rollers above them. Besides turning on their own axes, a lateral as well as a backward and forward motion is given to the rollers, which produces a high polish on the needles. The older method of polishing needles is to put many thousands of them along with putty powder and oil in a canvas bundle wound round with a cord. A number of these rolls or bundles are then placed between two wooden slabs—the upper one heavily weighted—and made to roll backwards and forwards in a polishing-machine for several hours. When taken out of the canvas and the polishing material adhering to

Neewinlen, a small village in the north-west corner of the Belgian Congo, provided for the victory gained by the French under Luxembourg over the English under William III. (29th July 1693), and also for the defeat of the French under Dommerey at the allied under the Prince of Coburg (18th March 1713).

Ne Exeunt Regno is the title of a writ issued by the king of England to prevent an individual leaving the kingdom, unless he gives security to abide a decree of the court.

Neff, Felix, a Protestant pastor, born at Geneva, 8th October 1798, was in his twenty-sixth year ordained, in England, to minister to the neglected inhabitants of the lofty Alpine valleys in the east of the department of Hautes Alpes. His parish was a most difficult one to minister to, owing to its mountainous nature and great extent (80 miles long), and the uncivilised character of the people. But with unwearied devotion and simple piety Neff laboured amongst them like his chosen model, Oliver Cromwell (q.v.), whose death he denounced 12th April 1829. See Memoirs and W. S. Gilly (1832), and Letters and Biography (trans. from French of Best, 1843).

Negapatan, a seaport of British India, on the Comorandean coast, 180 miles S. by W. of Madras city. Originally a Portuguese settlement, it was taken by the Dutch in 1660, and by the English in 1781. The port trades in cottons, live-stock, ghi (exported), hemp, rice, pepper, coal, gum-nuts, and (imported), to the total annual value of £600,000, chiefly with Burma, the Straits Settlements, and Ceylon. Pop. (1891) 59,221.

Negligence. See LIABILITY OF EMPLOYERS.

Negritos is the name given by the Spaniards to certain Negro-like tribes inhabiting the interior of some of the Philippine Islands, and differing both in features and manners from the Malay inhabitants of the Eastern Archipelago. They seem to be more closely akin to the Andaman Islanders than to either Papuans or other stock; and are also known as Aetas or Ilas (see PHILIPPINE ISLANDS). The name is also applied in a wider sense for the Papuans and all the Malayesian peoples of Polynesia (q.v.). For certain negroid African peoples, see ETHNOLOGY.

Negros. The negroes and people of negro characteristics at home are dealt with at AFRICA and ETHNOLOGY. In America the negro is the result of African descents, whether of the true negro or of Bantu stock. The total number of negroes, pure or mixed, in America has been recently estimated as somewhat above twenty millions, of whom about one-third are in the area of the United States. Their importation has been going on steadily since the early years of the 16th century, when it was begun by the Spaniards, even the good Las Casas recommending it in the interest of the native Indians. Both Queen Elizabeth and King James I. issued patents to English slave-trading companies, and the coast of Guinea and the American colonies. England, by the treaty of Utrecht (1713), engaged to carry out the contract of the old French Guinea Company, and to import into the New World 130,000 slaves in the course of the next thirty years, and is said to have more than made good the engagement. In the United States the traffic was open and active until the passage of the Act of 1794 prohibiting the importation of slaves into any of the federal ports. Long after this it continued to be a brisk business in the West Indies and South America. In 1840 there were seventy-five ships plying constantly between Brazilian ports and the African coast, bringing cargoes of 300 or 400 slaves at each trip. The principal points at which the slaves were obtained were along the coast of Guinea, especially on what was known as the Slave Coast, between the rivers Lagos and Assinie, where were the crowded marts of Waalish and Anamaboe, and again along the Angola coast, from 8° to 18° S. lat. In these two regions the traders encountered two quite different branches of the African race, and their human wares in America were show in colors from different sources. Along the Guinea coast, whence most of the slaves brought to the United States were derived, the population belongs to the true negro type. As most of the coast tribes enriched by the traffic did not sell their own members, but obtained the slaves from the interior by capture or purchase, we do not find traces of the Fins, Ashantis, or Dahomis in the negro population of America, but well-marked characteristics, both linguistic and anthropological, of the interior tribes, especially of the extensive Mandé or Mandingo, of the river Senegambia, are traced to this stock, and a method of counting in use among the negroes of Maryland about the beginning of the 16th century proved to be derived from the Mandingo numerals. In Brazil and other parts of South America the preponderance of importations is answered by the negroes of the triangulator, whose dialects and physical traits are allied to those of the Kaffirs and Zulus of the east coast (Bantu). The slaves in all parts, however, being from mixed stocks, their descendants do not present any well-marked anthropologic peculiarities outside those characteristic of the race. As their strength equal to the whites, and in endurance of exposure and labour under a tropical sun are superior to all other immigrants. The experiment was officially tried in British Guiana to ascertain
the relative working powers in field labour of negroes, Chinese, and East Indian coolies. The negroes performed twice as much labour as the coolies and a third more than the Chinese. The latter were the most intelligent in their work. It is usually held that the negro is not naturally industrious; but this seems to some extent answered by the severe field labour of many tribes, both men and women, in their native continent, and by the proportion of negroes to the white in the Southern States. The negro is industrious and provident, and the instances are numerous where members of the race have accumulated fortunes of respectable size. Their utility appears on the whole to be about the same as the whites, except in the more northern states, where it is unquestionably much less. Thus, according to the census of the United States in 1880, the total average annual mortality of the white male population was 15.06, while that of the black population was 17.19, a showing which might fairly be attributed to inferior physical position and consequent more careful observance of hygienic laws by the whites; but in the northern states of the Union there was a contrast which could not be so explained, but must be attributed to an inability of the African to withstand the cold of a high latitude. The proportion of deaths per thousand in Connecticut, Massachusetts, and New Hampshire was in 1880, among whites, 15.19-06, and 16.23; but among negroes, 22.41, 24.41, and 26.5. In 1890, in New England, New Jersey, New York, Delaware, and District of Columbia, the highest death rate was that in which the deaths per 1000 amongst negroes, 34.14; the lowest amongst whites, 15.60; amongst negroes, 19.78. See Vol. X. p. 380.

In New England and Canada negroes gradually but surely perish. The diseases to which they are especially subject are those connected with the organs of respiration, as pneumonia, consumption, affections, and bronchitis. On the other hand, in the south they are less subject to malarial diseases, to yellow fever, to hepatic derangement, and to sunstroke than the white population. It is generally conceded that they are not so liable to accidents from the use of firearms which may be attributed to the inferior susceptibility of their nervous systems. The special senses are usually acute and correct: colour blindness is four times commoner among whites than with negroes, and the vocal powers of the latter are perceptibly greater. From a number of autopsies of adult males carried out during the civil war, it results that the lungs are relatively smaller and the liver larger than in the whites. The assertion has been made that the average weight of the brain in the negro is about 8 pounds, which is less than 1 pound of the true African negro; but repeated dissections to disprove this statement. No change whatever has been observed in the colour of the African in any part of America so long as the blood has been unmixed. Observations con-duct that the hair may undergo some alteration, rendering it slightly less woolly; and it is stated positively that the odour peculiar to the negro is not found in the wild negroes of that country who have for generations lived apart in the woods. This is certainly the case with the negroes in the United States, and it is likely that the Guiana tribes are descendants of negroes from Angola, who have little or none of the odour of the true negro of the Soudan. There is a prevalent opinion that instances of uncommon longevity are more frequent among the coloured than the white population; and according to some statistics which have been published, the proportion of the population of the southern United States in proportion to its membership is a hundred times that of the French! The explanation of this is simply that old negroes very rarely know their own age and love to magnify it; in other words, no dependence is to be placed on these statistics. There is no evidence of exceptional longevity among them.

The change from one continent to another does not appear to have reduced the fecundity of the race, which, it is well known, stands at a high mark in Africa. It has been calculated that in the United States at present the white race increased annually at the rate of 2.9 per cent., while the coloured population, including all shades, increases 3.4 per cent. This preponderance much more than makes up for the slightly higher death-rate. It is, however, not directly attributable to a greater natural fertility, but to the fact that a coloured woman very rarely remains unmarried, and does not avoid offspring.

The disposition of the negro is usually pacific and cheerful. He is not easily depressed by poverty or thoughts of the future. Content that is immutable, whatever vicissitudes are meeting him, he prepares for a distant contingency. Eminent gregarious in his instincts, he is usually to be found in certain streets and quarters of the town exclusively occupied by members of his own race. His interest in the past is weak, and few or no reminiscences of his ancestors, languages, customs, superstitions, or usages have been retained. His religion is emotional, and exerts but a moderate influence on his morality. Frequently it is associated with superstitions beliefs and rites derived to some extent from Voodooism. Paralysis, which is believed by some that these are relics of the fetishistic worships of equatorial Africa, but the connection has never been demonstrated; on the contrary, the tales of the sacrifice of children; of ritual cannibalism, and of obscene ceremonies alleged to prevail in Hayti, are baseless. Whether the negroes of other parts of America, have been shown by W. W. Newell to rest on very doubtful authority, and, if they occur at all, are the actions of a very few superstitions fanatics. The word Voodoo, or, as usually pronounced in the United States, Vaudis or Vaudoi, is etymologically derived from the period of the persecution of the Vaudois or Waldenses, who were represented by their opponents as sorcerers and necromancers, whence the name Vaudois came to be synonymous with 'witch' or 'wizard.' By a similar Creole French corruption the word Wanga, which among the negroes of Louisiana and Hayti means a philter or charm, and as a verbal 'to bewitch,' is, in spite of its African physiognomy, the French Inquent, an incantation, such preparations being currently believed to possess magic powers. It is argued, therefore, that both the words and practices are of European origin. Nevertheless, it is unquestionably true that among the negroes both of the West Indies and the United States there is a prevalence in Hayti and in certain degenerate negroes of the victim and doing some injury to it, or by securing a little of his blood, or by burying certain roots in the path where he is accustomed to walk, or by scattering brown paper before the door of his
house, or in many other ways. In the West Indies and the bottle is the home in which he can most easily put an end
of an enemy. It is filled with pins, rags, pebbles, small
sticks, leaves of certain plants, &c. The result is often successful; for a negro who believes himself 'enjur'd' will refuse food, and sink into the profoundest dejection, resulting occasionally in death. That a serpent or wondrous flag of pro-
minent part in these Obi rites, as has often been stated, does not appear confirmed. Nor is it a pro-
minent figure in the stories and folk-tales of the race in America. These fictitious narratives are
very numerous, the negro being a tireless talker and
the most prolific of the art of story-telling, as the Georgia tales collected by J. C. Harris and Colonel C. C. Jones, and numerous others from the southern states by various
writers. Many of them belong to the class of 'beat-fables,' similar to some which have been collected among the American Indians and the natives of the African continent, and such as
were favourite staples of amusement in Europe during
the middle ages. One of the principal figures is the
rabbit (the 'brer rabbit' of the 'Uncle Remus
tales). He figures conspicuously not only in the southern United States, but in the states on the Amazon (Hartt), and as tio concejo ('rabe
rabbit') in the folklore of the Venezuelan negroes
(Dr Ernst). This unimportant animal also plays a
leading part in the mythology of various American-
Indian nations, as the Algonquins and Mexicans (31).
It appears unerringly that its prominence in negro-American folklore was a loan from this
source. Along with story-telling, singing and
music are favourite diversions of the coloured
population. This tendency is a direct inheritance
from their African ancestry, as throughout that
continent, the negro has been marked off in the
diversions. In Central America the negroes still
employ the marimba, a native African instrument with wooden keys placed over gourds or gourds, the keys being struck with a stick. In the United
States the violin, the fife, and the guitar are used,
but the favourite is the 'banjo,' an instrument of
African derivation, modified from the guitars with
grass strings still in use on the Guiana coast.
With these simple means they produce music of
delightful though not artistic character. In
individual instances (as Blind Tom, born in Georgia in
1849) many negroes have in a remarkable degree the
able skill on the piano and organ, rendering the most
difficult compositions with spirit. No negro composer,
however, has attained celebrity. Their songs are numerous, many of them of a religious
character, others turning on the incidents of daily
life. They are generally defective in melody and
without merit, being often little more than words
strung together to carry an air.

The negro is ambitious for education, but un-
willing to make the necessary mental effort to
obtain it. In the United States public schools
their progress is about equal to that of white
children, up to the important changes at the age of
puberty, when a visible ascendency of the appetites
and emotions over the intellect and an increasing
indisposition to mental labour supervene. In the
higher branches of the mental life, nothing is
the case, and if one of them undertakes the studies requisite
for a profession, he is content with what is barely
sufficient for its remunerative practice. Notable
results are attending the education of the negro in
mechanical and agricultural pursuits, however, in
the Central South (182); in 'fraternal' and
Turkseego, Alabama. The social position of the
negroes in some parts of South America differs little
from that of the whites. But in the United States,
despite the theoretical equality, the natural sense
of inequality between the races is making itself felt,
and they are probably now farther awander in symp-
thies than they were at the close of the war, in both
the northern and southern states.

Negroponte. See Euboea.

Negros, an elongated island of the Philippines,
between Panay and Zebiti. Area, about 5300 sq. m.
It is voleanic in origin, and is composed of volcanic
beds of the type chiefly found in the Canaries, and
it is crossed by densely-wooded mountains. It is fertile, yield-
ing tobacco, coffee, sugar-cane, and wheat, and pro-
duces fabrics of abaca and canneleongo.

Negus, a compound of either port or sherry and
hot water sweetened with sugar and flavoured with
lemon-pearl and spices, and served in a glass
on the west coast, is the chief town.

Negus. See Abyssinia.

Nehemiah, who, next to Ezra, among all the
men whose names have been handed down, had the
most important share in the making of post-exilic
Judaism, comes before us principally in certain
fragments of autobiography imbedded in the can-
onical book that now bears his name. From these
we learn that he was the son of a Levite, and
was at some time held the post of cupbearer at Artaxerxes Longi-
mannus ('King of Babylons,' xiii. 6), when, at the
winter-palace of Shushan or Susa, towards the end
of the year 445, he was surprised and saddened
with unexpected tidings of the very unprosperous
state of Jerusalem. According to the narrative of
Herodotus (v. 15), his next role was to reinforce the
population of the depleted capital by drafts from the
surrounding districts, and in particular, it would seem, to bring back
to town the Levites who, through non-payment of
dues, had been compelled to abandon service at the
temple and give themselves to field labour through-
out Judah. Arrangements having been made for
the regular support of the sacred offices, the feast
of the dedication of the walls was now gone about
with great pomp and joy. It is to be presumed
that Nehemiah returned soon afterwards to his
duties at the Persian court. We read (xiii. 6; cf. v. 14) of a second visit of Nehemiah to Jerusalem,
twelve years afterwards, on which occasion he either
initiated or renewed and completed certain reforms
which henceforth were among the most character-
istic features of the newly-restored temple service; and
most marked of these was the crusade against mixed
marriages and the separation of the Jews of
pure descent from the 'mixed multitude' (xiii. 3). His cleansing of the temple, and expul-
sion of Tobiah from its precincts, ultimately led, it
would seem, to the formation of the Persian
community as a separate religious organisation.
Another of Nehemiah's reforms was the stringent
enforcement of a strict law of Sabbath observance.
Others are to be found in the arrangements he made for the permanent maintenance of the temple
NEHEMIAH

NEIL.
NELSON

water-supply is good. There is a cathedral, a literary institute, and museum, public hospital, and asylum. The manufactures of the town comprise cloth, leather, soap, and jam. Pop. (1891) 6020; with suburbs, over 10,000.

NELSON. HORATIO, VISCOUNT NELSON, English admiral, was born on 29th September 1758, at Deptford, Kent, the son of a poor family; his father was rector. His mother, daughter of Dr. Suckling, prebendary of Westminster, was related to the Walpoles. He entered the navy in 1770, under the patronage of his uncle, Captain Maurice Suckling; made a voyage to the West Indies in a merchant vessel in the Winter expedition of 1773, and was afterwards sent to the East Indies in the Seahorse. Two years of the climate severely tried his constitution, never very strong, and he came home, invalided, in September 1776. In April 1777 he passed his examination, and by the interest of his mother's family was at once promoted to be lieutenant of the Lowestoft frigate, with Captain Locker. In her he went to Jamaica, where he was taken by the admiral into the flag-ship, and on 8th December 1778 was promoted to command the Boggler brig, from which, six months later, he was posted to the Hindostan frigate.

In January 1780 he commanded the naval force in the expedition against San Juan; in the heavy boat-work up the estuarial river his health broke down, and he returned to England in an apparently dying condition. A month's rest and careful treatment, however, restored him; and in August 1781 he commissioned the Albemarle, in which, after a winter in the North Sea, he went to North America, where he joined the squadron under Lord Hood, and made the acquaintance of Prince William Henry, afterwards William IV, with whom he always maintained the most cordial relations. In the spring of 1784 he was appointed to the Boreas frigate, again for service in the West Indies, where, by enforcing the Navigation Act against the Americans, he raised the ill-paid but richly-laden merchant vessels, which took effect in numerous actions for damages. The law, however, was clear on the point, and Nelson's proceedings were sustained, though not without causing him much trouble and annoyance.

At this station he married Mrs. Nisbet, the widow of a Dr. Nisbet of Nevis, niece of Mr. Herbert, the president of the island; and on the Boreas being paid off, in December 1787, he with his wife retired to Burnham Thorpe, where he lived for the next five years. His frequent applications for employment were unsuccessful, till, on the imminence of war with France in January 1793, he was appointed to the Agamemnon of sixty-four guns, in which he accompanied Lord Hood to the Mediterranean. When Toulon was given up to the Allies, Nelson was ordered to Naples to urge the necessity of sending a force to the Mediterranean, and to assist him in his return he was employed in the blockade of Corsica, and in the following spring commanded the naval brigade which largely contributed to the reduction of Bastia and of Calvi, where an unlucky blow from a bit of gravel, scattered by a shot, destroyed the sight of his right eye. In 1795 he was with the fleet in the two actions fought by Admiral Hood outside Toulon. In both the French were defeated with some loss, but they were allowed to escape, and Nelson in his private letters expressed an angry opinion that more might and ought to have been done.

In the autumn of 1798 Hotham was succeeded by Sir John Jervis, and during the whole of 1797 the strictest blockade of Toulon was enforced, Nelson being for the most part, as in preceding years, with a small squadron in the Gulf of Genoa, where he put a stop to all coasting traffic, and commanded the road along the shore so completely as to warrant his assertion that, had he had an adequate force, the invasion of Italy would have been impossible. Towards the close of the year Spain concluded a treaty of alliance with France by which her fleet was to be employed in the Mediterranean to co-operate with the French. Jervis thus found himself opposed by very superior forces; and, with Spain and Italy both in hostile hands, his position was no longer tenable. He withdrew the troops from Corsica, and retired to Gibraltar, and afterwards to Malta. He was informed that the Spanish fleet, which had been instructed to join the French at Brest, should not pass; and, on its endeavouring to do so, met it off Cape St. Vincent on 14th February 1797, and inflicted on it a signal defeat. This was rendered more decisive by the action of Nelson, who, having been appointed commodore, with his broad pennant hoisted on board the Captain, was in the rear of the line, and, interpreting a manœuvre of the Spanish admiral as an attempt to reunite the two divisions of his fleet, which Jervis had separated, went out of the line, cut him to pieces, and, with his indestructible, single-handed, the attack of the whole Spanish van. When support arrived and the Spaniards fled, the Captain had suffered severely; and Nelson, being unable to join in the pursuit, let his ship fall foul of the Spanish San Nicolas, which he boarded and took possession of, and, leading his men across her deck to the San Jose, took possession of her also.

Nelson's conduct on this occasion deservedly won for him the cross of the Bath; and, being promoted in due course to rear-admiral, he continued with the fleet off Cadiz till, in July 1797, he was sent with a small squadron to seize a richly-laden Spanish ship which had taken refuge at Santa Cruz. He was instructed to levy a heavy contribution on the town if the treasure was not given up; but the troops which he had asked for were not granted, the ships were powerless, and landing force at his disposal was quite inadequate. With it, such as it was, however, the attack was made on the night of 21st July; but in the darkness the boats missed the mole, and landing irregularly were repulsed with severe loss. Nelson himself had his arm broken by a grape-shot. He was carried on board his ship, where the arm was amputated, but on rejoining the fleet he was compelled to return to England.

In the following March, 1798, he hoisted his flag on board the Vanguard of seventy-four guns, and sailed from St. Helens to rejoin the fleet off Cadiz. He was immediately sent into the Mediterranean in command of a small squadron, with orders to ascertain the object of the French armament at Toulon. The secret was, however, too well kept; and the Vanguard, being disembarked in a violent gale, was driven ashore near the port of Sardinia to refit, while the French expedition sailed on its way to Egypt. On 7th June Nelson was reinforced by ten sail of the line; but his frigates had all parted company, and, under some misapprehension of orders, did not rejoin him. He was thus left without means of learning anything about the French further than that they had sailed from Toulon. His hope to get news at Naples proved vain, and it was only when he arrived off Messina that he heard that the French had landed at Calabria, but had sailed again some days before. Their destination was conjectured to be Egypt, and he hastened thither, only to find that there was no trace of them. He had in fact passed within a few leagues of them, but without seeing them. He returned by the coast of Asia, put into Syracuse, where he
watered, and was meditating going up the Archi-
pelago to Constantinople, when he at last learned
that, after all, they had gone to Egypt. Thither
he immediately followed, and on the evening of
1st August found their fleet lying at anchor in
Aboukir Bay. His plans had long before been
formed and discussed with Nelson, and, under
his orders, everything was ready, and no
explanatory signals were needed. His fleet was
numerically inferior to that of the French, and
became still more so by the accident of the
Culloden getting aground and being unable to take
part. A few days later, a thick fog hung along the
French line, and, by concentrating his
attack on the weather end of it, it was crushed by
superior force, while the leeward-most ships were
unable to render any assistance; and thus, creep-
ing gradually down the line, he captured or destroyed
the whole, with the exception of the two rear-
most ships, and two of the frigates, which fled.

Never, in recent times, had there been a victory
so complete, so overwhelming; and when Nelson
with his shattered fleet returned to Naples he was
the object of an enthusiastic adoration which knew
no bounds. The queen, in her intense hatred of
the murderers of her sister, welcomed their con-
queror with all the ardour of a passionate nature,
and Lady Hamilton (q.v.), the wife of the English
ambassador, fell on his breast in a paroxysm of
hysterical rapture. A woman of extreme beauty,
winning manners, and disdain antipathy to the
mistress and then the wife of Sir William Hamil-
ton, she ensnared Nelson by her charms, and the
two became bound by a liaison which death only
severed. At home Nelson was raised to the peer-
age and paid a state visit to that of the Nile;
parliament voted him a pension of £2000 a year,
and the East India Company awarded him a sum
of £10,000. Turkey and Russia sent him hand-
some and costly presents, and the king of Naples
conferred on him the title of Duke of Bronte, in
Sicily, with an estate valued at £5000 a year,
though during Nelson's life its revenues seem to
have been in abeyance.

The government of Naples had already concluded
an alliance with Austria and declared war against
France; but the French army swept away the
Neapolitan troops almost without resistance, and
the Neapolitan Jacobins received their French
brethren with open arms. For the king and his
court safety was only in flight, and Nelson con-
ducted them to Palermo. Afterwards, returning
and being authorized to annul the treaty of
the convention which Cardinal Ruffo, contrary to
the king's express orders, had made with the rebels;
he forced the traitors to surrender at discretion,
and he promptly hanged Caracciole (q.v.), one
of their leaders, who had added perjury to treason,
and having accepted a command as commodore in
the king's navy had betrayed his trust, and waged
war against the authority he was pledged to main-
tain.

The affairs of Naples were not yet regulated, the
outposts held by the French and their sympathisers
were not yet received for return, and Lord Byron
received an order from Lord Keith, the
commander-in-chief in the Mediterranean, to bring
or send the greater part of his force to Minorca,
which he conceived to be threatened by a joint
attack of the French and Spanish. Nelson was
obliged to obey the order; and when it was repeated in still
more positive terms, he contented himself with
sending Sir John Duckworth, his second in com-
mand, while he himself remained at Naples or
Palermo, and controlled the blockade of Malta
which a goodly part of his fleet of 12 ships was doing
the whole time. The Admiralty censured him for his
disobedience; and indeed it could scarcely be main-
tained that the affairs of Naples were of such
paramount importance as to justify this extra-
ordinary breach of discipline, the motives of which
have been much discussed. Perhaps the true
explanation of his conduct is that a severe wound
in the head, which he had received at the Nile,
and after serious illness, caused a depression of spirits which it needed some
violent stimulus to overcome. Happy at last in
the capture of the two ships which had escaped
from Aboukir Bay, he obtained leave to resign his
command, which the state of his health rendered
impossible, and not only helped the forces of
Vienna and Dresden, in company with Lady
Hamilton and her husband, for whom he professed
and appears to have truly entertained a real
affection and esteem. He arrived in England in
November 1800. The four months spent on the
journey had done much to re-establish his health,
and he immediately volunteered for active service.
His meeting with his wife could not possibly be a
happy one; and after an angry interview they parted never to see each other again.

On 1st January 1801 Nelson was promoted to be
vice-admiral, and was appointed second in command of the expedition ordered to the
Baltic, under Sir Hyde Parker. He hoisted his flag in the St George, but that ship being too
large for the approaches to Copenhagen, he moved into the Elephant when the attack was determined on.
The whole squadron that attacked his ship was
trusted to Nelson, with the smaller ships of the
fleet, Parker, with the others, remaining at anchor
some miles distant. After a furious combat of
from three to four hours' duration, the enemy's
ships were all destroyed, Nelson receiving no
injuries, and his followers only a few, one
being killed, most of the latter being severely
wounded. Nelson returned to England a hero, and
the evening of his arrival at Blundell's Hill, a
procession of some thousands of people collected in
Boulogne, his watch being so vigilant that the boats never ventured from under the protection of their chains and batteries.

On the renewal of the war Nelson was at once
sent out to the Mediterranean, where, with his flag in the Victory, he cruised for more than eighteen
months in front of Toulon, drawing back occasion-
ally to Madrague for water and refreshment.
During one of these absences, in March 1805, the
French fleet put to sea under the command of
Vice-admiral Villeneuve, and got clear away to
Gibraltar, to Cadiz, and to Martinique, where they expected to return to England. Nelson, however, though delayed for six weeks by his ignorance of where Villeneuve had gone, was
only twenty days behind him; and Villeneuve,
deceived as to the English numbers, and unwilling
to risk an engagement which might frustrate his
ulterior objects, hastily returned to Europe. Nelson
again followed, again outdistanced his enemy, and
arrived off Cadiz some days before the French
approached the shores of Europe. Then, conceiv-
ing that Villeneuve's aim might be to overpower
Nelson, Villeneuve's fleet of 13 ships, he quickly
joined it with most of his ships, returning himself to
England. It was but for a few weeks. Within a
fortnight it was known that Villeneuve had gone
to Cadiz, and Nelson was ordered to resume
the command. He did so on 25th September, and for
the next month kept a close watch on the port,
while his fleet was being gradually increased in
numbers. He was especially desirous that he
should have a war-ship for his flagship, and
not merely an honourable victory gained by an
inferior fleet, but the annihilation of the enemy.
Villeneuve was meantime urged by positive
and repeated orders to put to sea, and on 20th October,
having learned that some of the English ships
had gone to Gibraltar, reluctantly made out. Of
French and Spanish ships combined there were
with him thirty-three; with Nelson there were
twenty-seven.

At daybreak on the 21st the two fleets were in
presence of each other off Cape Trafalgar, and
Nelson, as usual, was at the head of the line of
centred on the Royal Sovereign, broke through the rear of
the Fregatte. Nelson, with the other division,
had reserved to himself the duty of over-
awing the van, till, convinced that they had no
intention of turning to support their rear, he bore up and threw himself on their centre.
He first ordered all the captains of Villeneuve's fleet,
ship, she fell foul of the Redoutable of seventy-
four guns, and her quarter-deck became exposed to
the musketry fire from the Redoutable's tops. Nelson,
while standing speaking to Captain Hardy, fell
mortally wounded by a shot on the left shoulder, which, striking obliquely downwards,
was passed through the spine. He was carried below,
and died some three hours later, just as the battle
ended in the decisive victory of the English. The
enemy's fleet was annihilated.

Nelson's body was brought home, and, after lying
in state at Greenwich, was interred with much
pomp in the crypt of St. Paul's. In the cathedral
above a gorgeous monument has been erected to
his memory, and numerous others throughout the
land bear witness to the deep feeling which his
splendid services awakened.

His Life by Clarke and M'Arthur (2 vols. 1809)
is written with more credulity than critical accuracy.
Southey's famous Life (2 vols.) dates from 1813. The
best record of Nelson's services is his Dispatches and
Journals of Vice-Admiral the Hon. Sir H. D. B. P. Huskisson
(2 vols. 1844-45); there is a selection from the Letters and
Dispatches (1866) and a Life (1896) by the author of the
present article; Capt. A. T. Mahan's Life of him is dated
1897. See also Jeffreys's The Queen of Napius and
Lord Nelson (1888), and Lady Hamilton and Lord
Nelson (1888).

Nelson, Robert, was born in London on 23d
June 1656, a rich Turkey merchant's son, and,
after a brief school at St. Paul's, removed
with his widowed mother to Dryfield in Gloucestershire,
where he was brought up by Dr. George Bull.
In 1680, the year of his election to the Royal
Society, he went with his wife Theresa on a
months' tour in France and Italy, returning from Italy with
Lady Theophila Lucy (1654-1705), a widow, and
dughter to the Earl of Berkeley, who in 1683
became his wife, and who soon after was converted
to Catholicism by Cardinal Howard and Bossuet.
He lived there till 1685, when he returned
from Italy at the time of the Revolution; but Nelson was from
the first a (passive) Jacobite, and on his return to
England in 1691 he joined the Nonjuring. He
was received back into the Established Church in 1710,
though he still would not join in the prayers for
Queen Anne; and he died at Kennington on 16th
January 1714. A man whose whole life was
devoted to doing good, one of the earliest members
of both the S.P.C.K. and S.P.G., the 'pious' Robert
Nelson was the author of five devotional works, of
one of which, the Festivals and Feasts (1703), 10,000
copies were sold in four and a half years.

See the Lives by W. H. Tesse (2 vols. 1840-46) and
G. F. Seale (2 vols. 1906); also Abbey's English Church in
the Eighteenth Century (now ed. 1887).

Nelson River issues from the north end of
Lake Winnipeg in Canada, and, after a north-easterly
course of 400 miles through Keeewatin,
falls into Hudson Bay. It discharges an enormous
quantity of water, and is navigable for 127 miles
from its entrance though only some 70 or 80 miles
for large steamers. For the railway from Winni-
peg, see Hudson Bay.

Nelumbo (Nelumbium), a genus of aquatic
plants included by some botanists in the natural
order Nymphaceae (q.v.); but by others consti-
tuted into an order, Nelumbineae, differing in
the want of albumen in the seed, and in the distinct
carpsels, which are buried in the cavities of a large
fleshy receptacle. The flowers and leaves are
very similar to those of water-lilies. The species
are few, and are found in the warm parts of Asia,
in the north of Africa, and in North America.
They are represented by two species distinguished by the beauty of their
flowers. N. speciosum is the Egyptian Bean of
Pythagoras, the Lotus and Tumara of the Hindus,
and the Lien-Hoa of the Chinese. By the ancients
it was regarded as the emblem of fertility; with
it the Egyptians decorated the heads of their
idoles Isis and Osiris. The Hindus hold it sacred,
and with them it is the floating shell of Vishnu
and the throne of Brahma. The Tibetans embellished
their temples and altars with it. It is
also much esteemed and cultivated in China and
elsewhere in the East for its seeds, roots, leaf-
stalks, and flowers, all of which are eaten.
It has been used as food by the Egyptians from
remote antiquity. The seeds are in size and shape
like acorns, with a taste more delicate than that
of almonds. The root contains much
sweet honey, and a kind of arrowroot may be
obtained from it; and powdered, it makes excellent
soup with milk or water. Great
quantities are pickled with salt and
vinegar, and eaten with rice.
The flowers are
generally rose-coloured, seldom
white. The ancient
Egyptian model of
sowing this plant,
by enclosing
each seed in
a ball of clay
and throwing
into the water, is practised at the
present day in India. — N. luteum
is a North Amer-
ican species, with yellow flowers, extending almost
as far north as Philadelphia. The farinaceous
roots are agreeable when boiled.

Nemathelminthia, or NEMATHELMITHES (Gr. 
Nema, 'a thread', and helminthos, 'an intestinal
worm'), a general name applied to the thread-
worms or nematodes, such as Ascaris (q.v.), Guinea-
worm (q.v.), to the somewhat distinct
Gordius or hair-cells, and to the more remotely allied Acanthocephala or Echinorhynchus (q.v.).

**Nematodes.** See Threadworms, Parasitic Animals.

**Nemea,** anciently the name of a deep and well-watered valley of Argos, in the Peloponnesus, between Corinth and Phlius. It lies north and southwest, and is from two to three miles long and more than half a mile broad. It possessed a sacred grove, with a magnificent temple of Zeus, and was celebrated for the games called the Nemean Games, one of the great national festivals of the Greeks. See Eleusis; Sisyphus.

**Nemertea,** an important class of 'worms,' the members of which are mostly marine. They are unsegmented, covered with cilia, and often brightly coloured. Their habitat is usually in sand or mud, but many are able to swim, while a few are parasitic. In diet they seem to be mainly, if not wholly, carnivorous. The body is very extensi, and in Limus maximus may measure 15 feet in length. Most of them break readily and even spontaneously, the fragments being in some cases able to form a fresh head and body. Among their remarkable qualities may be noted the presence of a highly penetrable offensive proboscis which lies quite apart from the gape in a special sheath along the back, and the occurrence of two curious ciliated pits, perhaps respiratory in function, opening on the sides of the head, and sometimes reaching as far inwards as the brain. Two nerve cords extend from the brain along the sides of the body, occasionally approaching one another ventrally or even dorsally. The sexes are separate, and there is frequently a remarkable metamorphosis in development. According to Professor Hübner, the nemerteans probably include, and the two head-altae distinct affinities with vertebrates.

**Nemesis,** according to Hesiod, the daughter of Night, was originally the personification of the moral feeling of right and a just horror of criminal actions—in other words, the moral conscience. Afterwards, when an enlarged experience convinced men that a divine will found room for its activity amid the little occurrences of human life, Nemesis came to be regarded as the power who constantly preserves or restores the moral equilibrium of earthly affairs—preventing mortals from reaching that excessive prosperity which would lead them to forget the reverence due to the immortal gods, or visiting them with wholesome calamities in the midst of their happiness. Hence originated the latest and loftiest conception of Nemesis, as the being to whom was entrusted the execution of the decrees of a strict retributive providence—the awful and mysterious avenger of wrong, who punishes and humbles naughty evil-doers in particular. Nemesis was thus regarded as allied to Athé (q.v.) and the Eumenides (q.v.). She was represented in the older times as a young virgin, resembling Venus; in later times, as clothed with the tunic and peplus, sometimes with swords in her hands and a wheel at her foot, a griffin also having his right paw upon the wheel; sometimes in a chariot drawn by griffins. There was a famous temple of Nemesis at Phthia in Thessaly, where important fragments of the statue of Nemesis by Phidias were discovered in 1890.

**Nemi, Lake of,** an extinct crater, 20 miles S. of Rome, accounted for its beauty the gem of the Alban Mountains. There was here a famous terraced theatre, renowned for its real and artificial lakes recently excavated. Irenaeus' Prêtre de Nemi (1885) gives the place additional interest.

**Nemphila,** a genus of herbaceous annuals belonging to the Hydrophyllaceae, with pinnatifid leaves and conspicuous flowers. Natives of North America, they are cultivated in European gardens, the N. insignis being prized as a border plant on account of its showy flowers, blue with a white centre. Other species are N. atronaria and N. mucronata.

**Nemours,** an ancient town of 4266 inhabitants in the French department of Seine-et-Marne, 40 miles SE. of Paris by rail, gave a ducal title to the second son of Louis-Philippe (1814–90).

**Nenagh,** a market-town of Conty Tipperary, 28 miles NE. of Limerick by rail. The ancient Norman keep called Nenagh round, is a striking object. Pop. 4722.

**Nennius,** the reputed author of a Historia Britonum, evidently of Cynric origin. It gives the mythical account of the origin of the Britons, the Roman occupation, the settlement of the Saxons, and closes with the twelve victorious battles of King Arthur. The writer is extremely credulous and feebile in judgment, but he has preserved valuable fragments of earlier treatises. The name of Nennius occurs in two prologues extant, but these are suspiciously superior in style to the poor Latin of the history itself. The text was edited by Stevenson for the English Historical Society in 1838. See De la Borderie's Historia Britonum (Paris, 1883), works by Skene and Ryhs, and Zimmer's Nennius Vindicatus (Berlin, 1893).

**Neocomian.** See Cretaceous System.

**Neolithic.** See Stone Age.

**Neophyte** (Gr. neophutos, from neos, 'new,' and phos, 'light,' 'I grow'), the name given in early ecclesiastical language to persons recently converted to Christianity. The word is used in this sense by St. Paul. Neophyte is also applied in Roman usage to newly-proclaimed priests, and sometimes, though more rarely, to the novices of a religious order.

**Neoplatonism,** the last form of Hellenic philosophy, the system of an illustrious succession of ancient philosophers who claimed to found their doctrines and speculations on those of Plato. Strictly speaking, however, the Platonic philosophy expired with Plato's immediate disciples, Speusippus and Xenocrates. Neoplatonism is an attempt to combine Plato's doctrine of the Ideas, developed by Aristotle, and supplemented with an ethical system akin to that of the Pythagoreans, with the doctrine of Ennemation; it does for Hellenism something like what Philo did for Judaism. Such amalgamation came about most naturally in Alexandria. Placed at the junction of two continents, Asia and Africa, and close to the most cultivated and intellectual regions of Europe, that celebrated city naturally became a focus for the chief religions and philosophies of the ancient world. Here the East and the West, Greek culture and oriental enthusiasm, met and mingled; and here Christianity sought a home, and in its turn helped to liberate nations which strove to quell the myriad discons of Paganism. Authorities have differed as to how much should be included under the term Neoplatonism. By some it is used to designate the whole new intellectual movement proceeding from Alexandria, comprising the branch of the schools of Philo-Judaism and of Numenius the Syrian; of Christian Fathers like Clemens Alexandrinus and Origen; of the Gnostics; and of Ammonius Saccas and his successors. But the best authorities restrict the application of the term to the followers of Plotinus and his immediate disciples, including Proclus and Clement of Alexandria, the last having been a pupil of Plotinus.
NEOPLATONISM

Neo-Platonists aimed at constructing a religion on a basis of dialectics. They strove to attain a knowledge of the Highest, and the way in which they endeavored to accomplish this was by assuming the means of salvation for man—beyond the limit of his empirical knowledge, and acquiring an intuitive knowledge of the absolute, the true—that which is beyond and above the fluctuations and dubieties of 'opinion.' This personal faculty is called *Eudiae.* By means of it, men could, however, to be individual man—can identify himself with the Absolute (or Infinite). Plotinus, in fact, set out from the belief that 'philosophy' is only possible through the identity of the thinker, or rather of the subjective thought, with the thing thought of, or the objective thought. This intuitive grasp or 'vision' of the Absolute is not constant; we can neither force nor retain it by an effort of will; it springs from a divine inspiration and enthusiasm higher and purer than that of poet or prophet, and is the choicest 'gift of God.'

The goal of Plotinus and the other Alexandrians is a mystical Trinity. The Dionysian Institute contains within it three Hypostases (Substances); its basis, if we may so speak, is Unity or Primitive Light. This Unity is not itself any thing, but the principle of all things; it is absolute good, absolute perfection; and, though it is utterly incapable of being comprehended, yet it is comprehended by a man which assures him that it—the incomprehensible, the ineffable—is. From Unity, as the primordial source of all things, emanates Pure Intelligence (*Nous*); its reflection and image, that by which it is intuitively comprehended, is from Pure Intelligence, by a certain similarity of nature, the 'Soul at the World,' whose creative activity produces the souls of men and animals, and 'Nature'; and, finally, from Nature proceeds 'Matter,' which, however, is subjected by Plotinus to such refinement of definition that it loses all its grossness—though he could not call it dualistic, and glorifies in the beauty of the world. Unity, Pure Intelligence, and the World-Soul thus constitute the Plotinian Trinity, with which is connected, as we have seen, the doctrine of the eternal Emanation. Human souls, whose source is the Pure Intelligence, are subjective mysterious fancies, in perishable bodies, in which the higher sort are ever striving to reascend to their original home.

The most distinguished pupil of Plotinus was Porphyry, who mainly devoted himself to expanding and qualifying the philosophy of his master. He was the first of his time to observe the distinctively anti-Christian tendency. Neo-Platonism, which can only be properly understood when we regard it as an attempt to place paganism on a philosophical basis to make the Greek religious philohelms, and the Greek philosophers religious—did not consciously set out as the antimonist of Christianity. Neither Ammonius Saccas nor Plotinus assailed the new faith; but as the latter continued to grow, and to attract many of the most powerful intellects of the age into its service, the higher light in all its glory could not be seen for the affluence. Porphyry wrote against Christianity; Iamblichus, the most noted of his pupils, did the same. The latter also introduced a theurgic or 'magical' element into Neoplatonism, teaching, among other things, that certain mystical exercises and symbols had particular influence in the after-life. Magic and spiritualism are always popular, and it is therefore not wonderful that Iamblichus should have had numerous followers. Aedesius succeeded to his master's chair. From the school of one of his disciples, Maximus, came the Emperor Julian, whose patronage for a moment shed a gleam of splendour over Neoplatonism, and seemed to promise it a universal victory.

After a succession of able but not always consistent teachers, among whom is to be reckoned the noble Hypatia, we reach Proclus, the last great Neo-Platonist, who belongs to the 5th century, a man of wonderful learning, and of an enthusiasm for the temperance, in whom the pagan-religious, and consequently anti-Christian, tendency of the Neo-Platonism culminated. His method was based on the Tract of Plotinus, but was considerably modified in detail; he exalted 'Faith,' and above all he advocated an eclecticism to the Christian religion was keen; in its success he saw only the triumph of a vulgar popular superstition over the refined and beautiful theories of philosophy; it was as if he beheld a hoarde of barbarians defacing the statues and records of the Pantheon. The disciples of Proclus were numerous, but not remarkable for talent. Perhaps the ablest of his successors was Damascius, in whose time the Emperor Justinian, by an arbitrary decree, closed the schools of the heathen philosophers. Neo-Platonism soon ceased to exist as a system; but it survives in many of those endeavors to reconcile the ancient thinkers to Plato and Aristotle, it served as the nurse of Christian mysticism, and it had helped to mould the mind of Augustine. From a scientific point of view it was retrogressive, perverse, absurd; yet in the moral and religious sphere it maintained a high and holy ideal, and inspired a firm belief in that which is above the empirical.

See Zeller's 'History of Greek Philosophy;' Ueberweg and the other historians of philosophy; Herzog-Pfitz's 'Realencyclopadie;' the church histories; Kingsley's 'Alexandria,' and E. C. Wright, 'The Christian Platonists of Alexandria' (1891); Simon, 'Histoire de l'Ecole d'Alexandrie' (1845); Vacheret, 'Histoire critique de l'Ecole d'Alexandrie' (1851); and the articles herein on PLATO, STOICISM, PHILO, ORIGEN, Gnosticism, Plotines, Porphyry, Iamblichus, PROCLUS.

**Neo-Pythagoreanism** stood to Pythagoras somewhat as Neo-Platonism did to Plato, and was an Alexandrian development under oriental influences. It originated in the first half of the century before Christ, and was gradually the more widespread. Neo-Pythagoreanism may be divided into two groups, according as their aims were mainly practical—the purification and ennobling of life by asceticism, including theurgy, or more modestly metaphysical—fusing their views on the Pythagorean theory of numbers (see PyTHAGORAS). Of the former school Apollonius (q. v.) of Tyana is the most conspicuous example; of the latter, Moderatus of Gades, Nicomachus of Gerasa (2d century A.D.), Archytas (q. v.), and Sextius. See the works cited at NEOPLATONISM.

**Neozoic.** (Gr., 'new life'), a term introduced by Edwards to include the Epoch, and his Hypothesis from the Trias to the most recent deposits. Few geologists have adopted the term; the systems in question being generally divided into the groups of Secondary or Mesozoic, Tertiary or Cainozoic, and Quaternary or Post-Tertiary.

**Nepal**, an independent kingdom of India, lying on the northern side of the Himalayas, is bounded on the N. by Tibet, on the S. and W. by Bengal, and on the E. by Sikkim, a protected state. Long. 80° 6'-88° 14' E. It is 512 miles in length, by 70 to 150 in breadth. Area, 54,000 sq. m.; pop. estimated by native authorities at more than 5,500,000, though probably half that number is nearer the mark. The northern parts of the state embrace the main range of the Himalayas (q.v.),
with its offset spur, on which stand the great peaks of Everest, Dhaulagiri, &c. On the south of the state lies the Terai. The intervening territory consists of mountain-ridges, embracing several valleys drained by the Kurnali, Gandak, Kosi, and other rivers. The climate of course varies greatly according to the position of the valley and the altitude, which stands the capital Kathmandu (q. v.), has a climate like that of southern Europe. The soil is very fertile, in some districts producing three crops in the year. The hillsides are terraced and the land is irrigated. Rice, opium, rape, linseed, tobacco, and in the higher valleys, apples, are the more important products. Several minerals, as copper, iron, sulphur, and others exist, but are little worked. The forests contain valuable timber trees. Nepal has extensive trading relations with the provinces of British India, reaching the annual average of £2,000,000, and with Tibet, the details of which are not known. The valleys are inhabited by numerous different hill-tribes, partly aboriginal, partly Mongolian or Chinese descent; but the dominant race are the Gorkhas (q. v.), with spottings of peoples from the Himalayan slopes from Rajpootana in the 12th century, though it was not until 1769 that they made themselves masters of Nepal. They rapidly subdued the hill-valleys to east and west of them, and, after a war with China (1789-92), on account of Tibet, in which the Gorkhas were defeated, and a state of internal disorder, Nepal came into conflict with the Indian government. War followed; in 1815 Sir David Ochterlony defeated the Gorkha armies in the west, and peace was agreed to; but, the treaty not having been signed by the king of Nepal, a British force, 25,000 strong, advanced in the succeeding year to within three days' march of Kathmandu, and compelled the Gorkhas to sign the treaty. Since that they have ceased their encroachments on British territory, and during the Mutiny voluntarily sent to the assistance of the British army in the reduced Indian monarchy. The real ruler of the country is the prime-minister; Sir JangBahadur held this office from 1846 to his death in 1857, and was succeeded by his son. But he was slain and supplanted by the head of a rival faction in 1855.

Nepentes. See INSECTIVOROUS PLANTS.

Nepheline (Gr. nepheli, 'a cloud'; in allusion to the mineral becoming cloudy when immersed in a strong acid). It is a valuable and useful mineral and of great importance. It is colourless, white or yellowish, and usually crystallises in hexagonal prisms with various modifications. It has a hardness of 5½ to 6, and sp. gr. of 2½ or thereabouts. It occurs in various varieties, as nepheline-basalt (nepheline-basalt), in which it plays the part of felspar in ordinary basalt (plagioclase-basalt). In these fine-grained rocks the crystalline granules of nepheline are of microscopic size; in the more coarse grained nepheline-basalts (nephelines) the crystals are readily seen by the naked eye. Fine crystals often occur in drusy cavities in such rocks. Ellaeite (Gr. elaeion, 'oil') is a variety of nepheline with a greasy lustre, which seldom assumes a crystalline form. It is dark greenish, gray, or brown in colour, and appears to occur only in the rocks of the seventies of Frederiks-værn and Laurvig in Norway.

Nephelium. See Litchi.

Nephrite, a mineral usually called Jade (q. v.), and known also as Belstein, or Axestone. It is a hard, tough mineral found in Turkestan, in Siberia, in Blutan, in New Caledonia, in the Marquesas, in British Columbia, and in Alaska. It is a composition of silicate of calcium and magnesius, with lime, alumina, sodium, and protoxide of iron. The bright green of some of the more highly-prized specimens is probably due to oxide of nickel. Some specimens in India (where it is not native) strike fire with steel, and are therefore not pure nephrite. What is most generally known as oriental jade is a pale-greenish nephrite, more or less opaque, very hard, and is found only with a dull or greasy feeling to the touch. This quality is more often seen in vases, &c., the finer and rarer colours being used for personal ornaments. Much of what is called Oceanic jade, because found in the South Sea Islands and New Zealand, is not true nephrite, but is nevertheless a beautiful and valuable variety. Two or three names (Greek nephros, 'kidney') was supposed to be a charm against nephritic diseases, and had many other virtues ascribed to it; in China to this day jade ornaments are believed to afford protection from lightning. The Old Aryan belief in this may account for the wide distribution of jade ornaments although deposits of the mineral are so limited. The specimens of nephrite obtained from prehistoric finds in Europe were believed to have been imported from Asia. But recently the mineral has been found in the western valley of Silesia; and the water-worn fragments found at Neenburger See have probably been derived from some local source not yet detected.

Nephritis (Gr. nephros, 'kidney'), inflammation of the Kidneys (q. v.).

Nepomuk (or Pomuk), John of, the patron saint of Bohemia, who is honoured as a martyr of the seal of confession, was born at Pomuk, a few miles S.E. from Prague, about 1330. Having been, at the university of Prague and taken holy orders, he held various ecclesiastical offices in Prague, and was appointed confessor to Sophia, wife of King Wenceslaus IV. For refusing to betray to this monarch the confession of the queen John was put to the torture, then tied hand and foot, and flung into the Moldau, in March 1383. His memory was cherished with peculiar affection by the Bohemian people, and in 1729 he was canonised by Pope Benedict XIII. His memory is celebrated on 16th May. By some historians two distinct personages of the same name are held to have been the subject of the confessional, the other, a victim to the Simoniacal tyranny of Wenceslaus; but the identity of the two is sustained by Palacky, Geschichte von Bohmen, iii. 62. In 1855 Abel tried to prove that John of Nepomuk was a merely Catholic transformation of the people's popular saint, St. Wenceslaus, and the historical John Huss. See Wratilshaw's Life, Legend, and Canonisation of St John Nepomucena (1873).

Nepos, Cornelius, a Roman historical writer, was a native of Pavia, as Memmuseus thinks, of Hostilia (now Ostiglia), as its citizens believed they proved by erecting a statue in 1868. He was the contemporary and friend of Cicero, Atticus, and Catullus, and was probably still alive in 25 or 24 B.C. The ancient ascribed to him the following works: Chronica, Exemplorum Libri, Lives of Cato and Cicero, and De Viris Illustribus. The last is supposed to have consisted of sixteen books, but only two or three have been preserved. On the Roman and statesmen, mostly Greeks, who have survived. These biographies are trustworthy as history, but are written in a clear and elegant style, although affected archaisms and euphonic mannerisms are not unfrequent. Until the middle of the 6th century they were ascribed to /Emilius Prolus (4th century); but in 1569 the famous Dionysius Laminus claimed them as part of the lost work of Cornelius Nepos. Other good editions are those of Cellarius (1689) and, in modern days, Nipperney (2d ed. 1873). See Frenenberg, Questiones Historicae in C. Nepotis vita (1839).
Nepotism (Ital. nepote, ‘a nephew’), a word used to signify the system or custom practised by several popes subsequent to Innocent VIII. of granting high honours, dignities, offices, pensions, and the like to their family relations, generally their nephews, altogether irrespective of merit.

Neptune, the Italian god of the sea. Attempts have been made to show that his worship goes back to Aryan times, by identifying his name with the Sanskrit and Iranian Apsam Napat, ‘offspring of the water.’ But this is one of those unfortunate identifications which show that comparative mythology, dealing with the data of primitive philosophy. Further, as there is nothing whatever to make it the least probable that Neptune was ever anything but a sea-god, and as the primitive Aryans were not acquainted with the sea, it is evident that he cannot have been an Aryan deity. Indeed, as it was not until after the Italians had entered Italy that they became at all familiar with the sea, it was probably not until after they had settled in Italy that they made acquaintance with Neptune. Nor is there any probability that he was their own invention. We may conjecture that he was borrowed by them from the Etruscans, a maritime nation, who worshipped as their sea-god Netuns or Nethuns. Had the Italians never come into contact in historical times with the Greeks, Netuns or Neptuns would have remained a mere abstraction, like all other Italian deities, who were rather assuming than personal beings. But communication with Greece resulted in the Italians identifying their god of the sea with Poseidon (q.v.), the Greeks’ god of the sea.—For the planet Neptune, see PLANETS; for the Neptunist theory, see GEOLOGY, Vol. V. p. 148.

Nerbudda (more correctly NARBADA), a river of India, rises on the Amarkantak plateau, 3493 feet above sea-level, in 22° 41’ N. lat., 81° 49’ E. long., and flows west, through the Central Provinces, past Jabalpur (190 miles from its source), through the great depression between the Vindhyah Mountains on the north and the Satpura Mountains on the south, known as the Valley of the Nerbudda, and reaches the Gulf of Cambay half-way between Baroda and Surat. It has a total length of 800 miles, and drains 36,400 sq. m. It is navigable as far as Brouch, 39 miles from its mouth. The river ranks as a sacred stream in the thoughts of the Hindus, and is likely to supersede the Ganges in sanctity. It is regarded as a meritorious act to walk from the sea to its source and back again alongside the river.

Nerchinsk. See NERCHINSK.

Nereid. See NYMIP.

Nereis, a common genus of marine worms or Chaetopods, the members of which live in the sand or mud of the sea. See CHAETOPODS, and WORMS.

Nerl, PHILIP, the founder of the Congregation of the Oratory and a canonised saint of the Roman Catholic Church, was born at Florence, July 21, 1515, and was the youngest son of Francesco Neri, an attorney in that city. His singular modesty, his piety, and affectionate heart won for him in his boyhood the name of ‘Good Pippo.’ Philip’s uncle, a prosperous merchant, determined to make him his heir; but a view of abandoning all worldly pursuits, left his family and betook himself in his eighteenth year to Rome. Here for many years he lived as a layman a humble and retired life. A Florentine gentleman gave him a small room as a lodging and an allowance for his board. Philip spent most of his time in visiting the sick, in instructing the poor and ignorant, and in solitary prayer in the catacombs. It was not till 1651, when he was thirty-six years of age, that he was persuaded to become a priest. He then took up his residence in the little church of S. Girolamo, and gathering round him a number of disciples, some of whom were men of good family and high attainments, he started the exercises of devotion which made his name famous. At first these simple services or prayer-meetings were held by a few young men in his own house. In 1558 they were transferred to an oratory which he was permitted to build over the nave of the church. These daily services, which were a great novelty at the time, consisted of three sermons of about half an hour’s duration, delivered by the orator with an air of magnificent philosophy, and interspersed with vocal hymns, readings, and prayers. The preachers were for the most part laymen. During the day Philip took many of his penitents round the hospitals. His object was to make religion attractive, especially to the young. At the carnival or in holiday seasons he instituted musical entertainments and the acting of religious dramas, the origin of the modern oratorio. At other times he took numbers of men in procession through the streets on a pilgrimage to the seven churches, alternately singing hymns and praying in silence, and would take refuge in the garden of some wealthy friend. It is said that before Philip’s death the number of these pilgrims rose to two thousand.

In 1564 Philip had some of his companions ordained priests, and established among them a community life at a church given to him by the Florentines. One of these priests was Cesare Baronio, the historian of the church, and afterwards cardinal. Ten years later the community, now much increased in number, moved to S. Maria in Vallicella, on the site of which Philip built a larger church, known as the Chiesa Nuova, or New Church. Here the institute of the Oratory received the formal approbation of the pope, and here Philip died, May 25, 1595.

The saint was not an orator or a learned man, and although he was the favourite of popes and cardinals, as he was of the poor, he never received any ecclesiastical office or dignity. He never meddled with politics or public affairs. But his gentle and joyous nature, his tender charity, and the example of his innocent life were among the most potent of the influences which brought about the revival of ecclesiastical and the reformation of morals in Rome during the last half of the 16th century, and which earned for him the title of ‘the Apostle of Rome.’ Many miracles were attributed to the saint, even the raising of the dead. A notable phenomenon connected with his life is one which is to Philip what the stigmata were to Francis of Assisi—a strange palpitation of the heart and fracture of the ribs attributed to the supernatural effects of divine love—which came upon him suddenly one day at prayer in the catacombs. Philip was canonised with Ignatius Loyola, Sts. John and Charles Borromeo in 1672.

Philip’s literary remains consist of a few letters (Svo. Padua, 1751) and some sonnets printed in the collection of the Rime Onesti. The best life of the saint was written by one of the fathers of the congregation, Giuseppe Galletti, in 1629, and before Philip’s canonisation at Como. Vite beati P. Philii Neri in annos digesta, by Ant. Gallonio (1600). An English translation, made from a later edition of Basili, appeared under the editorship of Faber (1784). A popular Life has been written by Mrs Hope (Burns and Oates, 1839); and see also the Life by Archbishop Capellacaro (Eng. trans. 1882).

Néris-les-Bains. See MONTLUCON.

Nero, the last of the Cæsars and the mystic anti-christ of primitive Christian tradition, Roman emperor from 54 to 68 A.D., was born at Antium, on the coast of Latium, 16th December
NERVAL

37, and was the son of Cn. Domitius Aheno-
barbus and of the younger Agrippina, the daughter
of Germanicus Caesar, and sister of Caligula.
His uncle heeded the advice of the young Claudius,
who adopted him (50), his name, originally L.
Domitius Ahenoabarbus, being changed to Nero.
Claudius Caesar Drusus Germanicus. After the
death of Claudius (34) the Pretorian Guards, at
the instigation of Afranius Burrus, their prefect, de-
declared him the successor of his uncle's Britannicus,
and their choice was acknowledged both by the senate and by the provinces.
His reign began with the semblance of moderation and
good promise, under the guidance of Burrus and his inter Senex the philosopher; but the baleful
influence of his mother, together with his own moral
weakness and sensuality, frustrated their efforts,
and he soon plunged headlong into debauchery,
avanguard, and tyranny. He caused the young
Britannicus, the son of Claudius, to be treacher-
ously poisoned, and put to death (39) his own brother
Agrippina to be murdered, in order to please his
inamous and ambitious mistress Poppea Sabina.
To marry her he divorced and put to death his
nephew Octavia, the sister of Britannicus.
The Roman senate showed the depth of its degra-
dation by the address among them rebuking
the hateful matricide on the death of Agrippina,
but Nero himself was ever haunted by the ghost of
a murdered mother. The affairs of the empire were
at this time far from tranquill. In 61 an insurrec-
tion broke out in Britain under Queen Boadicea,
which was suppressed by Suetonius Paulinus.
Next year saw an unsuccessful war against the
Parthians in Armenia. At home the emperor
from lampoon in verse; Burrus, a valuable friend,
died; and even Seneca, though no rigid moralist,
could not make the sacrifice of his life, and he
was removed from court. In July 64 occurred a great
conflagration in Rome, by which two-thirds of the city
was reduced to ashes. Nero himself is stated by all
authorities later than Tacitus to have been the
incendiary; and we are told that he admired the
spectacle of a distance, reciting verses about the
burning of Troy. But he found a convenient scape-
goat in the mysterious sect of the Christians, many
of whom were put to death with unheard-of cru-
delies, such as being wrapped in cloth steepled with
pitch, and set on fire in the imperial gardens.
Moreover, among the city's cupidity, and reared for himself on the Palatine Hill
a splendid palace, the famous 'golden house,' and in order to provide for this expenditure and for the
gratification of the Roman populace by spectacles and distributions of corn Italy and the provinces
were plundered without ruth. A conspiracy against
Nero in the year 65 failed, and Seneca and the poet
Lucret fell victims to his vengeance. In a fit of
passion he murdered his wife Poppea, by kicking her
when she was pregnant. He then offered his
hand to Antonia, the daughter of Claudius, but
was refused, whereupon he caused the too fastid-
ious lady to be put to death, and married Statilla
Messallina, after putting her husband to death.
He also executed or banished many persons highly
distinguished for integrity and virtue. His un-
distinguished companionship as a poet, a philosophe-
r, an actor, a musician, and even a charioteer, and he received sycophantic applause,
not only in Italy, but in Greece, to which, upon
invitation of the Greek cities, he made a visit in 67.
But in Spain, Gaul, and Spanish regions, and after them the Pretorian Guards, rose against him
and made Calica emperor, and Nero fled from Rome
to the house of a freedman, Phoön, about four miles
distant. The senate now declared him an enemy
of his country, and the trembling tyrant saved himself from execution by suicide, 11th June 68.

His last words throw light on his pitiful vanity
and on the cruel irony of fate that placed him on
a throne—'What an artist is lost in me.' See
the translation Berlioz. Britain repress his
dignited talents, but they were not sufficient
for the diffeonce, dudgeous influence of his mother, together with his own moral
weakness and sensuality, frustrated their efforts,
and he soon plunged headlong into debauchery,
avanguard, and tyranny. He caused the young
Britishus, the son of Claudius, to be treacher-
ously poisoned, and put to death (39) his own brother
Agrippina to be murdered, in order to please his
inamous and ambitious mistress Poppea Sabina.
To marry her he divorced and put to death his
nephew Octavia, the sister of Britannicus.

of his country, and the trembling tyrant saved himself from execution by suicide, 11th June 68.

Neroll. Gérard DE, the adopted name of Gérard Labrunie, one of the most attractive but
ill-starred figures among the French Romantiasts,
was born at Paris, May 21, 1808, son of an officer
in the Grand Army. He was educated along with
Gautier at the Lycée Charlemagne, and early took
to letters, publishing at twenty a translation of
Faust which pleased Goethe, and gave his chowes to
Berlioz. He earned a living as a music-cutter cut
short by death, fits of restless travel, of dissipation,
and of glook that at times deepened into mental
darkness, and at last death, almost certainly by
his own hand, 25th January 1855, sum up the
wretched story of his life. He moved in a romantic
dream-world all his days, squandered money when he
had it prodigally upon brie-à-brac, read deeply in
Greek, Italian, German, English, and Arabic,
and wandered carelessly over Italy, Germany,
Greece, Syria, Palestine, and Egypt. Gérard de
Nerval wrote admirably alike in prose and verse,
his style even in his highest and most natural,
and original, imbued with a subtle personal charm of a quite remarkable
caracter. But his travels, criticism, physis, and
poems, good literature as they are, are far less interest-
ing than his Aurelie, ou le Rêve et la Vie
(1855), an imitations of his own madness. 'This
strange work,' says Andrew Lang, 'does for insan-
ity what the Dream of Gerontius has done for
death.' In Les Illuminés, ou les Précédeurs du Socialisme (1832), he discusses the mysticism of
certain highly endowed men in its relation to
distinct aspects of mental life, and works of which
will be found in his fantastic short tales, which have
an exquisiteness of their own that approaches
near perfection. These are the Contes de Facéties (1832), and the semi-autobiographical series of
Filles de Feu, containing Sylvie, Angelique, Jenny,
Octavius, Isaia, Emile, Corrila (1836). Another book of singular interest is the melange entitled La Bohême Galante. Some of his most charming poems are graceful adaptations of French peasant folk-songs, the beauty of which he had ears to hear.

His Œuvres complètes were collected in 5 vols. in 1868. See Andrew Lang in Fraser's Magazine, May 1873.

Nervi, a powerful and warlike people of the ancient Gallia Belgica, their territory stretched from the Sambre to the ocean, not subdued by Caesar without an obstinate resistance.

Nervousness is a term somewhat vaguely used, both popularly and by medical men, to express an unduly excitatory condition of the nervous system, manifested by unusually ready manifestation of emotion—e.g. starting at slight causes—by morbid sensitiveness, by unreasonable apprehension, by trembling of muscles, and in many other ways. The condition may be natural, or produced by ill-health or acute disease. It is more common in children than in adults, and in the female sex than the male. Care should be taken to improve the general health by good nutrition, regulation of the bowels, open air exercise, bathing, change of air and scene, and the ordinary tonic remedies; stimulants and drugs should be avoided save under the special direction of a medical man.

Nervous System, the mechanism by which an animal acquires a knowledge of the external world, and by means of which the great functions of the absorption of food, the elimination of waste products from the body, the respiration, circulation, and muscular action, are regulated and controlled. In its simplest form, in some of the lowest animals, it consists merely of nerve-fibres going to and from a small group of nerve-cells; but from this elementary condition there is an ever-increasing degree of complexity till its highest development is reached in man, which alone is included in the following description. In the articles on Birds, Fishes, Reptiles, Mammals, &c., will be found paragraphs on the nervous systems of the various classes of animals.

The nervous system is composed of a series of organs—nerve-cells, nerve-fibres, and nerve end-organs. The nerve-cells are situated for the most part in the brain and spinal cord, but also in other parts of the nervous system. Their function is either to receive, to send out, or to modify as they transmit, nerve impulses. The nerve-fibres transmit nerve impulses to and from the nerve-cells. For this reason groups of nerve-cells are often conveniently spoken of as nerve centres; their relation to the nerve-fibres being analogous to that of a telegraph-office to the wires connected with it. The end-organs are the special structures for receiving impressions, such as the various organs of special sense, smell, sight, hearing, taste, touch (see Nose, Eye, Ear, Taste, Touch), and for transforming outgoing impulses into muscular contractions or secretion, &c. The nerve-fibres terminate in an end-organ, which is an end-organ of a nerve centre, or two nerve centres with each other. These three sets of organs, nerve centres, fibres, and end-organs, are grouped into two great systems—the cerebro-spinal (fig. 1) and the sympathetic (fig. 10) system. The former is composed of the brain, spinal cord, and the cranial and spinal nerves respectively connected with them. The sympathetic system is formed by a double chain of small swellings, called ganglia, on either side of the front of the spinal column, and connected with each other, with the spinal nerves, and the internal organs by fine nerve-fibres (figs. 7 and 10).

Fig. 1.

a, cerebrum; b, cerebellum; c, medulla oblongata; d, spinal cord, from which the spinal nerves arise; e, brachial plexus; f, sciatic nerve.

The nerves are whitish cords varying greatly in size. They are composed of nerve-fibres which are bound together by fibrous tissue. This forms a sheath on the outside (the perineurium), and sends processes inwards between the individual nerve-fibres (fig. 4 shows a transverse section of part of a nerve, with the bundles of connective tissue passing inward). In the spinal cord and brain the nerve-fibres are held together by a special kind of connective tissue, called neurolamin.

Structure of Nerve-fibres.—A fibre from a spinal nerve has the following structure. In the centre is a very fine fibre or thread called the axis cylinder. This runs without any interruption along the whole length of the nerve. It can be traced into a nerve-cell at one extremity, and into an end-organ at the other; and there is reason to believe that it is really an outgrowth from a nerve-cell. It is the essential constituent of a nerve, that namely along which the nervous impulse travels. The axis cylinder is in its turn composed of still finer fibrillae, which may break up into finer nerve-fibres. Except at its origin and termination, the axis cylinder is covered by a tubular membrane called the medullary sheath, or the white substance of Schwann, a whitish substance of a peculiar fatty nature. This is interrupted at intervals of about 1/36th of an inch by constrictions which (fig. 2) pass completely through its thickness. When a nerve is stained with nitrate of silver, a black colour is formed at the intersections, and for a short distance along the axis cylinder (see fig. 3, where two are represented). These interruptions
are called nodes of Ranvier, after their discoverer, and are supposed to allow of the percolation of lymph to nourish the axis cylinder. When a nerve is divided transversely, and stained appropriately, the axis cylinder appears as a small point surrounded by a ring of the whitish medullary sheath (fig. 4). This sheath is enclosed by a continuous investment, the primitive sheath. This is colourless, and very delicate, and has a nucleus on its inner side corresponding to each segment of the medullary sheath. In the sympathetic system the medullary sheath is absent; while the fibres of the brain and spinal cord retain the medullary sheath, inch in diameter; in the brain they may be nearly ten times finer.

The nerve-cells vary greatly in size and in form. Many of them, especially in certain regions of the cortex of the brain, have the shape of an elongated pyramid (fig. 5, B), with fine processes coming off at various points, others are very irregular in outline, but also with numerous processes, one of which can frequently be traced into continuity with a medullated nerve, and hence is called the axis cylinder process, while the others form a fine network before entering another cell or fibre. Such cells are called multipolar (fig. 5, A and C), and are seen best in the anterior horns of the gray matter of the spinal cord. Many cells, again, are bipolar—i.e. they have only two fibres, one at each pole, in connection with them.

The various end-organs are described under the special sections. Fig. 6 shows the manner in which the fibres of a nerve end in a muscle.

The nerves arising from the brain are arranged in twelve pairs. The first, or olfactory, is the nerve of smell. The second, or optic, is the nerve of sight. It arises from the retina, meets with its fellow in the optic chiasma, and is distributed half to each side of the brain, terminating partly in the corpus quadrigemina (for the reflex movements of the eye), and partly in the optic thalamus, passing thence to the occipital lobe of the cerebrum (for the sense of sight). The third or oculo-motor nerve arises under the name of the medullary sheath, and passes to all the muscles of the eye except two, which are supplied by the fourth and sixth pairs. The fourth nerve, arising immediately behind the third nerve, supplies the superior oblique muscle of the eye; while the sixth pair, arising from a nucleus near the middle of the floor of the fourth ventricle, supplies the external rectus muscle of the eye. The fifth pair has a very long origin from a point at the level of the third nerve down to the upper part of the spinal cord. It is the motor nerve to the muscles of mastication, and the sensory nerve in the face, front of the head, teeth, nape of the neck, is the nerve of taste of the anterior part of the tongue. It is this nerve which is concerned in neuralgia of the head and face and teeth. The seventh pair arises from the lower part of the pons Varolii (see Brain), and is the motor nerve to the facial muscles of expression. Injury to or disease of this nerve causes facial palsy, or Bell's paralysis. The eighth pair, or auditory nerve, supplies the internal ear. It is divided into two parts, one of which supplies the cochlea, and is the nerve of hearing proper, while the other supplies the semicircular canals, and is concerned in the maintenance of the equilibrium of the body. The nerve arises from the lateral and posterior part of the pons Varolii and medulla oblongata. The ninth pair, or glossopharyngeal nerve, is the special nerve of taste, and supplies the hinder third of the tongue, with the taste bulbs of which it is connected. The tenth pair, or pneumogastric nerve, has a very wide area of distribution to the lungs, heart, stomach, &c.; it is partly motor and partly sensory in function. The eleventh pair, or spinal accessory nerve, is the motor nerve to the larynx, and to certain muscles in the upper part of the neck. These three nerves arise from a groove in the side of the medulla oblongata and
upper part of the spinal cord. The twelfth pair, or hypoglossal nerve, is the motor nerve of the tongue. Its origin is near the fifth pair of vertebrae close to the middle line, and it emerges from the anterior surface of the medulla oblongata in a shallow groove between the anterior pyramids and the inferior olivary body (see Brain).

The spinal nerves arise from the spinal cord in pairs, thirty-one in number, and are named according to their relation to the vertebrae—cervical, dorsal, lumbar, and sacral. Their mode of origin will be understood from fig. 7, which represents diagrammatically the first part of their course, and on one side their relations with the sympathetic system—C 1-8 represent the eight pairs of cervical nerves; D 1-12, the twelve dorsal pairs; L 1-5, the five lumbar pairs; and S 1-6, the six sacral pairs. Each spinal nerve arises by two roots, an anterior and a posterior (fig. 8, a and p; see also Spinal Cord). These roots pass outwards, and unite before they leave the spinal canal. Before their union a small oval swelling is found on the posterior root, and is called its ganglion, g. The united nerve leaves the spinal canal by a small aperture between adjacent vertebrae. It almost immediately gives off a fine medullated nerve to its corresponding sympathetic ganglion, a branch which can be traced into one of the internal organs. It also receives from the ganglion a non-medullated or gray fibre, which is distributed to the muscular coat of the blood-vessels, especially the arteries. The nerve thus altered passes outwards, dividing as it goes to send its ultimate branches into the fibres of the muscles, into the cells of the skin and connective tissues, tendons, and bones. In the dorsal region each nerve passes to its distribution without entering into connection with its neighbours, but in the cervical, lumbar, and sacral regions the nerves split up and form new junctions with each other, or plexuses as they are called. (These are marked by a, and b, and f in fig. 1, and on the right-hand side of fig. 7, but the detailed description of them is impossible within the limits of this article.)

Functions of the Spinal Nerves.—Sir Charles Bell discovered that division of the anterior roots was followed by loss of voluntary motion, and that division of the posterior roots destroyed the power of sensation. He termed the anterior root motor, and the posterior sensory. It has since been ascertained that the anterior roots carry outwards other impulses that do not result in motion, and that the posterior roots carry inwards impulses which may not result in sensation. Therefore, it is more correct to term these roots respectively different and afferent. If the anterior root be divided between the point of its origin from the cells of the anterior horn of the spinal cord and its junction with the posterior root, the part unconnected with the cord will waste along the whole length of the nerve, and the muscles which it supplies will waste also. The cells in connection with the anterior roots, therefore, not only send out motor impulses, but exert a nutritive or trophic influence on the nerve and muscle. Division of the posterior root beyond the ganglion is followed by wasting of the corresponding fibres of the nerve to their ultimate termination. If the root be cut between the ganglion and the spinal cord, the part attached to the ganglion remains unaltered, while that connected with the spinal cord wastes. This shows that the ganglion of the posterior root exerts a trophic influence on the fibres connected with it. If the nerve be divided after the junction of the two roots, the whole of the nerve farthest from the spinal cord will waste.

The afferent nerve impulses which pass along the posterior roots comprise those which give rise to the sense of touch, pain, and temperature, and to reflex movements of various kinds without necessarily exciting our consciousness, such as those concerned with the maintenance of the equilibrium of the body, and with the functions of the internal organs.

Reflex Action.—By this we mean an action brought about directly by the influence of an afferent impulse quite independently of voluntary control. For such an action four elements are necessary: (1) an afferent fibre, (2) nerve cells or centres, (3) efferent fibres, (4) muscle fibres. The impulse travels up the afferent fibres and stimulates the nerve-cells to send an impulse along the efferent fibre to the muscles. If an inhibitory factor is absent, the reflex action cannot take place. A familiar example is the movement of the foot as the result of tickling the sole. The afferent impulses pass up the nerve fibres, and the reflex action results. If a nerve is cut at the middle of its course, the afferent and efferent fibres are cut, and the reflex action will not take place. If a nerve is cut at the anterior horn, action will be restored, provided the cut is not made too near the anterior horn.

Automatic Action.—When movement is brought about by an impulse originated in a nerve centre itself, without the influence of an afferent stimulus, it is called automatic or spontaneous. Such actions are apt to occur rhythmically, such as the action of the heart.

Voluntary Actions.—In these the outgoing impulses originate in the nerve-cells in the motor area of the brain, and pass down the opposite side of the spinal cord to the nerve-cells in the anterior horn. From thence they are transmitted by the efferent nerves to the muscles. Fig. 9 will explain the relation of voluntary to reflex action; c is a nerve-cell in the brain; n, the nerve-fibre in the spinal cord which transmits the nerve impulse originating in c to a, a cell to the nerve centres in the spinal cord, which send outwards direct to the muscles motor impulses, which often cannot be controlled by the will.
motion will be lost, but the reflex arc, \(a, \alpha, s, e, m\), remains intact. We can sometimes control or

4, the two lines from this figure include the twelve dorsal ganglia; 5, the four lumbar ganglia; 6, include the five sacral ganglia; 7, the ganglion impar; 8, cardiac plexus; 9, solar plexus; 10, aortic plexus; 11, hypogastric plexus; 12, the aorta. \(a\), the trachea; \(b\), the aortic arch; \(c\), aorta; \(d\), external carotid; \(e\), internal carotid; \(f\), the heart; \(g\), the diaphragm; \(h\), the heart; \(i\), the thoracic aorta; \(j\), the liver; \(k\), the kidney; \(l\), the spleen capsule; \(m\), the sacrum; \(n\), the base of the skull; \(o\), the bladder; \(p\), the lower portion of the rectum.

repress a reflex action voluntarily. The cell \(c\) in the brain can so act on the cell \(s\) as to hinder or inhibit its ordinary response to a stimulus, and when the cell in the brain is destroyed the cell \(s\) is more easily stimulated reflexly, apparently because some restraining influence is removed. Such a restraining action is exerted on the heart by the pneumogastric nerve, which, when stimulated, slows or stops its movements; and in the same way the secretion of glands may be interfered with by abnormal stimulation of their nerve centres. This influence is termed inhibitory action, and is of great importance.

*Secretory Nerves.*—The nerves which induce the various acts of secretion leave the motor cranial nerves, or by the anterior roots of the spinal nerves; but the description of their distribution, &c., must be relegated to the article SECRETION.

The sympathetic system is, as already stated, composed of a series of ganglia situated on either side of the spinal column along its whole length. In the dorsal, lumbar, and sacral regions the ganglia correspond in number to the vertebrae; but in the cervical region there are only three, of such large size, however, that they are generally supposed to represent the fusion of a number of ganglia. Below, the two chains unite in front of the coecyx in a single ganglion. These ganglia are formed of multipolar nerve-cells (fig. 5, A), and are unipolar with each other by grey nerve-fibres. Each ganglion gives to its corresponding spinal (or cranial) nerve a gray non-medullated nerve, and receives from it a fine white medullated nerve. The fibres of distribution may be studied in fig. 10. They pass to the blood-vessels and to the mucous membranes and muscular coats of the various internal viscera, and become united with each other in fine networks or plexuses, on many of which nerve-cells or ganglia are situated.

The sympathetic chain is continued downwards as a fine plexus of nerves on the internal carotid artery, on the various branches of which it is distributed. From the superior cervical ganglion also fibres pass to the various arteries in the neck and face, and to form, along with the pneumogastric and glossopharyngeal nerves, the pharyngeal plexus on the muscles and mucous membrane of the pharynx.

From some of the cervical and upper thoracic ganglia fibres pass into the chest, to form also, along with the pneumogastric nerve, two important plexuses, named pulmonary and cardiac, from which branches pass to the lungs and heart, and undoubtedly influence their functions. From the thoracic ganglia also arise the three splanchic nerves which pass into the abdomen to enter the solar or epigastric and the renal plexus. The solar plexus is situated at the pit of the stomach, and is connected with two large semilunar ganglia, which send branches to all the blood-vessels and to all the organs within the abdomen. It is owing to the relations and functions of the solar plexus that blow in this region are so dangerous. The hypogastric plexus arises from the lumbar ganglia, and sends branches to the blood-vessels and to the organs in the lower part of the abdominal cavity, more especially the organs of generation, the lower bowel, and the bladder.

The functions of the sympathetic system are still
imperfectly understood. It supplies fibres to the muscles of blood-vessels to regulate their calibre; hence these fibres are called vaso-motor. The vaso-motor centre is situated, not in the sympathetic system, but in the medulla oblongata. The path for the fibres passes down the spinal cord, which it leaves as two sets at about three points along the white communicating branches into the sympathetic ganglia. From these ganglia the vaso-motor nerves for the internal organs pass into the various plexuses just described, while those for the vessels of the limbs and trunk return to the spinal nerves by the grey communicating nerves. Further, the muscular movements and secretions of all the internal organs are regulated through the sympathetic system.

Of the nature of nerve energy we know little. The nervous impulse travels along a nerve in man at a rate of about 34 yards per second, and it is accompanied by certain electrical changes in the nerve, but nerve energy is not identical with electrical energy. It is probably accompanied by molecular changes in the structure of the nerve as yet inaccessible to our means of investigation. It is likely, too, that the orination or discharge of nerve impulses in a cell is probably induced by similar but more active changes in its substance.

See Quain's Anatomy, Foster's Physiology, Landais's Physiology, and Obersteiner's Anatomy of the Central and Visceral Systems (translated by Hill).

Nels, TOUR DE. The ancient castle of the noble family Nels stood, with its gate and tower, at an angle of the city wall of Paris, on the south bank of the Seine, where now stands the palace of the Institute. It came into the hands of the crown, was the scene of events recorded by Brantôme, and was bought by Cardinal Mazarin as the site for his college.

Ness, LOCH, a long, narrow lake of Inverness-shire, the second largest in Scotland, 63 miles SW. of Inverness. Lying 50 feet above sea-level, it extends 22½ miles north-north-eastward, and has an average breadth of 1 mile, with an area of 19 sq. miles. It receives many rivers— the Moriston, Oich, Foyers (q.v.), and other streams, and send of the River Ness to the Moray Firth. It lies in the valley of Glenmore, on the line of the Caledonian Canal (q.v.), and is enclosed by steep mountains—the highest, Meallfournonie (2284 feet). Owing to its great depth and 750 ft. of fresh water, Ness forms to any considerable extent. See FORTE AUGUSTUS.

Nesselrode, KARL ROBERT, Count, Russian diplomatist, was born on the 14th December 1780, at Lisbon, where his father, a descendant of an ancient noble family on the lower Rhine, was then Russian ambassador. He gained in a high degree the esteem and confidence of the Emperor Alexander, and in 1814 he accompanied the Russian emperor to France, where he took a principal part in all the negotiations which ended in the peace of Paris; and he was one of the most prominent of the pleni-potentiaries in the Congress of Vienna, and one of the most active diplomatists of the Holy Alliance. The Emperor Nicholas reproved in him the same confidence, and amidst the European convulsions of 1848 and 1849 Russia, under his guidance, refrained from interference, till an opportunity occurred of dealing a deadly blow to the revolutionary cause in France. Being one of the chief of the moderate party in Russia, he directed himself to preserve peace with the Western Powers; and after the war had broken out in 1854 he undoubtedly strove for the re-establishment of peace. After the accession of Alexander II, he retired from the direction of foreign affairs, and was succeeded by Prince Alexander Gorchakov, but retained the dignity of chancellor of the empire. He died 23rd March 1862, and his autobiography appeared at Berlin in 1866.

Nessus. See HERCULES.

Nestor, according to ancient Greek legend, the son of Neleus and Chloris, born in the Mesopotamian Pylos, escaped destruction when Hercules slew all his brothers. He married Eurydice, by whom he became the father of a numerous family. In his youth his actions were distinguished for valor in wars with the Arcadians, Eleians, and the Corinthians, and in his advanced age for wisdom. Although he was an old man when the expedition against Troy was undertaken, he joined it with his Pylians in sixty ships. Homer makes him the great counsellor of the Greeks, and exhibits his eloquence as superior even to that of Ulysses. Nestor returned in safety to his own dominions after the fall of Troy, and continued for long to rule over the people of Pylos. —For the birds called Nestor, see KEA.

Nestorius, a native of Germanicia, a city of northern Syria, in the patriarchate of Antioch, was probably a disciple of the celebrated Theodore of Mopsuestia. The bishop and patriarch at Antioch, he became so eminent for his zeal, ascetic life, and eloquence in preaching that he was selected by the emperor as patriarch of Constantinople (April 428). Soon after his consecration a controversy arose as to the divine and human natures of Christ, and after four councils, in which the Emperor Justinian took the leading part. The presbyter Anastasius, having in a sermon denied that the Virgin Mary could be truly called the Mother of God (θεοτόκος), it being not God the Logos but only the human nature which he had a mother and suffered pain and death, Nestorius warmly denounced him and elaborated his view into the theory which has since been known by his name. He held that Mary was the Mother of Christ (παρθένους), or the Receiver or Conceiver of God (θεογόνος), and that, while the divinity of the Logos is to be distinguished from the temple of his flesh, yet there remained but one person in the God-man. By his antagonists he was accused of exaggerating the distinction of two natures into a co-existence of two persons (παρθένους-γονιμούς)—the human person of Christ and the Divine Person of the Word. A virous of the controversy ensued, which extended from Constantinople to the other patriarchates, and drew from Cyril of Alexandria a formal condemnation of the doctrine of Nestorius in twelve anathemas, and a similar condemnation, accompanied by a threat of deposition and excommunication, from Celestine, bishop of Rome, unless he would withdraw the obnoxious doctrine. Nestorius remaining firm in his opinions, a general council was convened at Ephesus in 431, at which Cyril took the most active and prominent part, and in which, notwithstanding the absence of John the Patriarch of Antioch and his bishops, Nestorius was condemned and deposed. Considerable opposition was offered to this judgment for a time, but ultimately the emperor was led to side with Cyril, and Nestorius was confined in a monastery near Constantinople, whence, after four years, he was banished to the island of Samothrace. He next found shelter in the Greater Oasis in Upper Egypt, and, after several changes of his place of confinement, died in exile, time and place alike unknown.

See Walch's Hist. d. Ktezesien ; Dorner's History of the Nestorians ; and the various Tracts on Nestorius; and the church histories of Giesebrecht and Neander.

The sect of the Nestorians, formed in the 5th century, was, after its exclusion from the Roman empire, extended into Persia, India, and Even China. The teachers who were driven out of Edessa settled at Nisibis, which soon became an active centre
of learning and missionary enterprise throughout Persia. Baber, Bishop of Seleucia (486-503), assumed the title of patriarch, and openly professed Nestorianism, and under his successors the sect grew rapidly and produced many learned theologians and philosophers, and not a few very eminent physicians. Under the rule of the califs the Nestorians were allowed to have existed in Arabia, Persia, Syria, and Palestine, and even to Sanaa and Harrat, and China. The Prester John (q. v.) of romance was a Christian of this colour, and there is a tradition that Mohammed learned what he knew of Christianity from Sergius, a Nestorian monk. In the middle of the 13th century the title of the patriarch of all Persia, and the lower Rhine, is now divided into nearly equal parts between the kingdoms of Holland and Belgium. The official designation of Netherlands is retained by what we commonly call Holland (q. v.), and under that head the early history common to the two is discussed while the history of the 'Spanish Netherlands' falls mainly under the head of Flanders (q. v.) and Belgium (q. v.). The history of the Dutch and Flemish language and literature will be found under HOLLAND.

Netherlands Company. See JAVA.

Neath. See PYRENEES.

Netley. A place on the east side of Southampton Water, 3 miles S.E. of Southampton, with a ruined Cistercian abbey, founded in the time of Henry III., and the Royal Victoria Hospital. The latter superb building is for the reception of invalids from the army on foreign service, and from among the troops serving in the adjoining military districts. It nominally has accommodation for 3000, but is intended only for a few months during the tropic season, and is usually to be found for over 1000. The medical staff consists of a surgeon-general as principal medical officer, a registrar and secretary, and medical officers of the rank of lieutenants, and the attached consists of a colonel on the staff ranking as an assistant adjutant-general, a paymaster, and a quartermaster. The total cost of the construction of this hospital, whose foundation-stone was laid by Queen Victoria on 19th May 1856, was about 2500,000. Attached is the Medical School for candidates for the army medical staff (see MILITARY SCHOOLS). Netley is also the headquarters of the female nurses of the army. A direct line from Portsmouth, the port of disembarkation of the troops, has been opened, and they can now be brought to this hospital in thirty minutes.

Nets. A net is a kind of trap formed of string worked into open meshes and used for capturing fishes, birds, and other animals. The cord or string is knotted at the intersections so as to keep the meshes of the desired size. As there is evidence that nets were used in prehistoric times, and since they are almost everywhere made by savage tribes, it is probable that they were among the earliest implements constructed by primitive man for procuring animal food. Remains of nets belonging to the stone age have been found at Robenhausen and Vinelz in Switzer-
NETTLE

The making of nets by hand is an extremely simple operation. Only two instruments are required—viz., a netting-needle like $a$ in the figure, for meshes above one-half inch in width, or one like $b$ for meshes under this size, and a mesh-pin, which is simply a straight piece of wood of oval section and a few inches long, upon which the loops are formed. If the meshes are to be one inch from knot to knot, then the circumference of the mesh-pin requires to be two inches. There are two ways of forming the knots on hand-made nets (see Knots, figs. 11 and 13), but both are equally simple, and the whole process can be learned in a few minutes by seeing an operator at work. In some countries nets are still largely made by hand.

Netting-machines are now extensively used for the manufacture of nets. The looms are of complicated construction, and it would require a considerable number of illustrations and detailed descriptions to give even a general idea of how they perform their work. One of the most successful of these is known as the Paterson net-loom. It was invented by Mr James Paterson, and subsequently (1835) brought into a more practical shape by Mr Walter Ritchie, both of Musselburgh. (The knot made by this loom is the same as fig. 13 of Knots.) It works by a peculiar arrangement of hooks, needles, and sinkers. Since the middle of the century Messrs J. & W. Stuart, who then took up Mr Paterson's business, have made some further improvements upon his loom. An improved form of a net-loom, on a different principle, invented by a Frenchman named Pegeon, in 1840, was subsequently patented in England. The designers of the later and more perfect form of this loom, which does its work well, are M.M. Bandonin and Jacquemart. Their English patent is taken out in the name of W. Clark, agent, and the specification, which contains a number of explanatory lithographs, is dated 19th September 1841 (No. 2340).

A variety of nets are used by fishermen, but the principal kinds are the seine, the drift-net, the moored-net, and the trawl (see Fisheries). The net used for taking the tunny in the Mediterranean is often nearly a mile long, and some Russian hand-made nets are 3000 feet in length. Means are adopted to improve the durability of cotton and hemp nets, especially of the former. One plan is to tan them; but, although this to some extent prevents the injurious action of sea-water upon them, it has the disadvantage of hiding faulty parts. They are, however, much more frequently backed in an infusion of rush (see Catechu), which preserves them a long time, and prevents the injury from sea-water upon them and at the same time limits the state of the meshes being better seen. A solution of alum is also useful in preserving the fibre of the string of which nets are made.

One or two kinds of nets are made for catching birds, such as fly-screen nets, and those suitable for seashore, and clap-nets for small birds (see Wild-Fowl). Fine nets are used to capture insects, and by the inhabitants of some countries as a protection from mosquitoes. Other kinds are employed to protect fruit and blossoms, for articles required on board ship, for mess-cooking, and for domestic purposes.

Nettle (Urtica), a genus of plants of the natural order Urticaceae, having unisexual flowers, the male and female on the same or separate plants; the male flowers with a 4-parted perianth and four stamens; the female flowers with a 2-parted perianth and two tufted stigmas; the ovary inferior, the antherenium. The species are herbaceous plants, shrubs, or even trees, many of them covered with stinging hairs (q.v.), which pierce the skin when touched, and emit an acid juice, often causing much inflammation and pain. When a nettle is grasped or pressed, it stings by making its way as much as possible along the stem no stinging ensues; but the slightest inadvertent touch of some of the species produces very severe pain. The acridity which is characteristic of all nettles, more or less, is by some said to be due to bicarbonate of ammonia, or according to others to formic acid being present in the filaments of the juice secreted by the glandular hairs of the leaves and stems. The stinging of the native nettles of Europe is trifling in comparison with that of some East Indian species. U. crenulata is particularly notable for the severity of the pain which it produces, without either parasites or apparent inflammation. The first sensation is merely a slight tingling, but within an hour violent pain is felt, as if a red-hot iron were continually applied, and the pain extends far from the original spot, sometimes causing severe neuralgia. The liquid is not like the juice of U. dioica, which is clear and thin, although it is stinging, and it causes severe pain and fibrosis. The juice contains formic acid, and the stinging is caused by this acid and the presence of an acid of the nitro-proprionic series. U. dioica is found in Europe, Asia, and America, and is the only species of the genus known here. Its specific name is due to the fact that it is commonly used for netting in Italy. Some of the species of U. are used for the manufacture of netting, and their juice is used in the manufacture of nets. The juice of U. dioica is said to be the most acrid, and is used for the manufacture of nets. The juice of U. dioica is also used in the manufacture of nets.

The roots of nettles, boiled with alum, afford a yellow dye; and the juice of the stalks is said to be a substitute for henna, and to be used for dyeing hair a beautiful and permanent green. The young shoots of U. dioica have been much used in some parts of Scotland and other countries as greens, and their peculiar flavour is much relished by some, although, in general, the use of them is condemned. They are also used as a vegetable food, and are rich in ascorbates, but are gritty to the taste from the quantity of crystals (Cystolithes) contained. Whatever it is that gives nettles their stinging power is dissipated by boiling and drying. The high
value of nettles as food for swine is well known to the peasantry of many countries; the great nettle is cultivated in Sweden for fodder of domestic stock, and nettles are pan highly esteemed as food for poultry, particularly for turkeys. The seeds are extremely nutritious to poultry, and are given to horses by jockeys, in order to make them lively when they are to be offered for sale. The stalks and leaves of nettles are employed in some parts of France and Switzerland. People of light kind of beer, called Nettle Beer. The bast-fibre of nettles is useful for textile purposes. Yarn and cloth, both of the coarsest and finest descriptions, can be made of it. The fibre of U. dioica was used by the ancient Egyptians, and is still used in Piedmont and other parts of Italy. When wanted to glide the plant is cut in the middle of summer, and treated like hemp. Nettle-cloth, or Grass-cloth, is a beautiful fabric made from rhea fibre (see Rheum). The fibre of U. candensis is used in the South Sea Islands; that of U. canadensis is used in Canada; and that of U. virginiana is described by Roxburgh to be the most ferocious-looking plant he ever saw, is of very glossy silky appearance, and is manufactured into cloth in Assam. The seeds and herbage of U. membranaceae are used in Egypt as emmenagogue and aphrodisiac; and somewhat similar properties are ascribed to U. dioica. U. tuberosa produces tubers, which are nutritious, and are eaten in India raw, boiled, or roasted. Australia produces a magnificent tree-nettle, U. gigas, abundant in some parts of New South Wales, ordinarily from 25 to 30 feet high, but sometimes reaching 100 feet, with trunk of great thickness, and very large green leaves which, when young, sing violently. The Dead-nettle (q.v.) is quite a distinct plant; so is the Nettle-tree (q.v.).

Netterash, or Urticaria (Lat. urtica, 'a nettle'), is the term applied to a common form of eruptions on the skin. The eruption consists of wheals, or little solid eminences of irregular outline, and either white or red, or most commonly both red and white, there being a white centre with a red margin. The rash is accompanied with great heat, itching, and irritation, but is always succeeded by a coolness. On the skin the eruption causes a strong itching and the sensation being very much like the appearance and feeling produced by the stinging of nettles; and hence the origin of its names. The eruption is characterised by the extreme rapidity with which it appears and disappears; the whole duration of the attack may be a few hours or even less; but it is extremely apt to recur at regular or irregular intervals: it is very rare for the wheals to persist more than a day.

The disease may be either acute or chronic. In the acute form the eruptions may precede the rash by a few hours, or may be altogether absent. The disorder is often connected with some derangement of the digestive organs, and may be traced to the imperfect digestion of special articles of food, such as oatmeal, the kernels of fruit, strawberries, cucumbers, and especially peas and mussels, and crabs, which are eaten with perfect impunity by most persons. It may be brought on also by local causes of irritation, and frequently complicates other irritable diseases of the skin.

The chronic form is often very troublesome, and frequently comes on periodically in the evening. Cases are reported in which persons have been afflicted for ten years continuously by this form of the disease. It is characterised by constant recurrence during long periods, not by persistence of a single outbreak of the eruption. In the treatment of the acute form of local causes of irritation must first be looked for and removed. Where it is brought on by some article of diet relief is often obtained by taking a teaspoonful of bicarbonate of soda (laking soda); but it may be necessary to administer emetics and purgatives, if vomiting and diarrhea follow. In the chronic form the patient should, in the first place, determine whether the rash is caused by any particular article of diet, and if this seems not to be the case an attempt must be made to improve the state of the digestive organs. A few grains of rhubarb taken daily, just before breakfast and before dinner, will sometimes effect a cure. Numerous other remedies have been recommended; perhaps the most generally useful is a draught containing a scruple each of the carbonates of magnesia and soda with five drops of tincture of nun vomica. Although external applications are usually of little avail, dusting the itching surface with flour sometimes affords temporary relief; and a still more useful application is a lotion composed of a drachm of the carbonate of ammonia, a drachm of the acetate of lead, half an ounce of linseed, and eight ounces of rose water.

Nettle-tree (Celtis), a genus of deciduous trees of the natural order Ulmaceae, with simple and generally serrated leaves, considerably resembling those of the Common Nettle, but not stinging. The genus is distinguished chiefly by its leaves, which is a fleshy, globose, or sub-globose 1-celled drupe. The Common or European Nettle-tree (C. australis) is a native of the south of Europe, the west of Asia, and the north of Africa. It grows to a height of 30 to 40 feet, and is a very handsome tree, often planted along public walks in the south of France and north of Italy. The wood is very compact, very durable, and takes a high polish. It was formerly much imported into Britain for the use of coachmakers, and is used in Italy by musical-instrument makers for the backs of violins. The flowers have six petals, two axillary, and solitary; the fruit black, resembling a small wild cherry, not eatable till after the first frosts, and then very sweet. The kernel yields a useful fixed oil. The tree succeeds well in the south of England. C. occidentalis is a native of North America, and is also called the Nettle-tree, Sugar Berry, Hackberry, or Haggerberry, and Hoe Ash. Its leaves are much broader than those of C. australis, its fruit very similar. It is a much larger tree, attaining a height of 60 to 80 feet. There are several varieties, which are sometimes but needlessly classified as distinct species. The inner bark of C. orientalis, consisting of reticulated fibres, forms a kind of natural cloth, used by some tribes of India. A number of other species are natives of the warm parts of America and Asia.

Neu-Brandenburg, a town of Mecklenburg-Strelitz, is situated on the river Töllens, 20 miles N.N.E. of Neu-Strelitz by rail. Pop. (1890) 9323.

Neuburg, an ancient town of Bavaria, picturesque situated on the right bank of the Danube, 29 miles N.N.E. of Augsburg. It has an old ducal chLOSS in the Renaissance style. Pop. (1890) 8750.

Neuchâtel, or Neufchâtel, (Ger. Neuenburg), a canton in the west of Switzerland, between Lake Neuchâtel and the French frontier. Neuchâtel lies in the midst of the Jura Mountains, four chains of which, running from north-east to south-west, traverse the canton, and are separated by elevated longitudinal valleys. The greater number of the
Neuilly, a town in the French department of Seine, immediately to the north of the Bois de Boulogne, and practically a suburb of Paris. Here, near the Seine, and in a large and beautiful park, formerly stood Château de Neuilly, built by Louis XVI., and the favourite residence of Louis-Philippe, which was burned at the revolution in 1848. When LouisPhilippe took refuge in England he assumed the title of Count de Neuilly. Pop. (1891) 27,351.

Neumünster, a prosperous manufacturing town of Holstein, on the Schwale, a head-water of the Elbe, near Kiel. It has many large cloth-mills, dye-works, breweries, &c. Pop. (1875) 10,124; (1885) 13,639; (1890) 17,539.

Neu-Pommern. See New Britain.

Neuralgia (Gr. neuron, ‘nerves; algos, ‘pain’) is a term employed to designate pain of a purely nervous character, usually unaccompanied by inflammation, fever, or any appreciable change of state. When the pain, instead of occurring in paroxysms, usually followed by complete remissions, is of every possible degree and character, being described in different cases as piercing, tearing, burning, &c. These paroxysms may occur at intervals of a few seconds only, or they may take place at intervals of hours or days, they may be separated by much longer intervals, which are often, but by no means always, of a regular length. The pain is usually felt not only at the place where the nerves terminate, but along their course. It is usually confined to one side of the body, and is very rarely produced by a stimulus or by a relatively quite small amount of irritation at its outset, and carries its waters into the neighbouring lake of Bienne, and thence into the river Aar. Pop. of the canton (1870) 97,284; (1888) 108,153, of whom three-fourths speak French, and four-fifths are Protestants. Asphalt and absinthe are expected to good effect here. The specialty of the canton is watch-making, which occupies from 18,000 to 20,000 persons, and is prosecuted mainly in the homes of the work-people. The history of Neuchâtel was identical with that of Burgundy till the 11th century; and after the principalities had from time to time incorporated the territories of the Counts of Chalon, to whom it had been granted in 1288 by Rudolph of Hapsburg, it passed to the House of Longueville. In 1707, on the extinction of the Neuchâtel branch of the latter family, some fifteen claimants came forward to advance more or less valid pretensions to the Neuchâtel territory. Frederick I. of Prussia, who based his claim to the principality of Neuchâtel on the ground of his descent from the first Prince of Orange, a descendant of the House of Chalon, was the successful candidate, and from this time it continued associated with Prussia till 1806, when Napoleon bestowed it upon General Berthier; but in 1814 it was restored to the House of Brandenburg. A republican constitution was adopted in 1848, in spite of Prussian protest; and there was civil war in 1856. The connection with Prussia was wholly dissolved in 1857, and Neuchâtel is now a member of the Swiss Confederation. See Switzerland.

Neuchâtel, chief town of the canton, occupies a magnificent site on the north-west shore of the Lake of Neuchâtel, 85 miles by rail N.N.E. of Geneva. It is noted for its many charitable, educational, and artistic institutions, and has a château (restored 1860), a college (1828), a statue of Farel (1875), &c. There are manufactories of watches, jewellery, &c. Pop. (1870) 13,321; (1888) 15,399. Neuchâtel is served by railways, made not here, but at Neuchâtel-en-Bray, a small Norman town, 25 miles SE. of Dieppe by rail.

Neuilly, or Neuilly-sur-Seine, a town in the French department of Seine, immediately to the north of the Bois de Boulogne, and practically a suburb of Paris. Here, near the Seine, and in a large and beautiful park, formerly stood Château de Neuilly, built by Louis XVI., and the favourite residence of Louis-Philippe, which was burned at the revolution in 1848. When LouisPhilippe took refuge in England he assumed the title of Count de Neuilly. Pop. (1891) 27,351.

Neumünster, a prosperous manufacturing town of Holstein, on the Schwale, a head-water of the Elbe, near Kiel. It has many large cloth-mills, dye-works, breweries, &c. Pop. (1875) 10,124; (1885) 13,639; (1890) 17,539.

Neu-Pommern. See New Britain.

Neuralgia (Gr. neuron, ‘nerves; algos, ‘pain’) is a term employed to designate pain of a purely nervous character, usually unaccompanied by inflammation, fever, or any appreciable change of state. When the pain, instead of occurring in paroxysms, usually followed by complete remissions, is of every possible degree and character, being described in different cases as piercing, tearing, burning, &c. These paroxysms may occur at intervals of a few seconds only, or they may take place at intervals of hours or days, they may be separated by much longer intervals, which are often, but by no means always, of a regular length. The
The causes of neuralgia are various. Excluding inflammation of the nerves trunk or neuritis, the pain may be excited by a tumour pressing on the nerve or originating in its substance, or by roughness of a bony wall for which it is not provided with an easy access: the nerve may be in contact, as when it passes through a foramen. Sometimes, again, irritation applied to one branch of a nerve will give rise to pain at the extremity of another branch of the same nerve, the sensation being reflected along the branch which is not directly irritated. Such cases of irritant neuralgia very frequently depend upon diseased conditions of the teeth, even if they themselves are not painful. In this way we may explain the pain in the shoulder which often accompanies disease of the liver; the pain in the thigh, which is often associated with irritation of the kidney; the pain in the left arm, which is often coincident with disease of the heart, &c. Persons suffering from debility, anemia, and a gouty or rheumatic constitution are so especially liable to neuralgia that these conditions, as also exposure to malarious influences in the form of fever or chill, are the prevailing causes. Amongst the exciting causes exposure to cold and wet, or to a cold dry eastern wind, is the most frequent; but fatigue, strong mental emotions, the abuse of tea, coffee, tobacco, and alcoholic drinks, a wound or bruise, the retrocession of gout, rheumatic aches and pains, &c., occasionally suffice to excite the disease.

The resources of the materia medica have been exhaustingly searched for remedies for this cruel disease. But, in the first place, a careful search must be made for any causal relation between the cause of irritation; and next, of the hygienic conditions must be very carefully attended to; fresh air, regular bodily exercise, freedom from worry and overstrain of mind, plenty of sleep, an abundant supply of wholesome nourishment, are each essential (Pagger). Fatty food, as cold liver oil, butter, cream, is of special importance.

Of drugs which give immediate relief to the pain, morphia, especially when administered hypodermically (see Hypodermic Injection), holds the first place. But it must be used with great caution, and not more than is needed to meet the momentary need; the 'neuralgic habit' becomes established. Antipyrin and aspirin, coal-tar derivatives recently introduced into medicine, sometimes take the place of morphia, and are free from some of its disadvantages. Croton-chloro- and bismuth are often useful in facial neuralgia. Relief from the suffering is often the first step towards recovery.

But in most cases some treatment is necessary to remove the constitutional state on which the neuralgia depends. Iron, quinine (especially when the pain recurs at regular intervals), arsenic, phosphorus, chloride of ammonium, are the medicines most generally useful. But the treatment must of course be adapted to the disorders, frequently digestive, present in each particular case.

Local applications can be of permanent service in cases where the pain results from organic change, or from general constitutional causes; they will, however, often give considerable temporary relief. Amongst the most important local applications may be mentioned klandanum, tincture of aconite or aconitins ointment, belladonna ointment, and chloroform saturated with it, and covered with oiled silk to prevent evaporation), mustard leaves or poultices, and small fly-blister. Galvanism is also valuable.

Lastly, neuralgia, being a purely nervous affection, is often influenced by means calculated to make a change in the general condition of the patient; and hence it is that galvanic rings, electric chains, mesmeric passes, and other applications which, like these, act more upon the mind than upon the body of the patient, occasionally effect a cure.

In cases which have resisted all other modes of treatment, surgical measures are sometimes necessary—viz. the excellence of stretching (see under SCITICA), or, in the last resort, removal of a portion of the affected nerve.

Neuritis, a term applied to inflammation of the nerves. The disease is not very common, and not very well defined. The symptoms are those of neuralgia, with impairment of sensation, or localised paralysis, according as sensory or motor nerves are affected.

Neuropoeta. See Insects.

Neusatz, a town in the Hungarian province of Baes, on the left bank of the Danube, opposite Peterwardein (q. v.). Pop. (1890) 34,717.

Neusiedler Lake, a small lake on the north-west frontier of Hungary, 22 miles S.E. of Vienna. It is shallow (13 feet), and has lost much of its former area (133 sq. m.) by the draining of the adjoining marshes—from 1865 to 1870 it was dry. Its brackish waters are valuable as medicinal baths.

Neuss, an ancient manufacturing town of Rheinish Prussia, near the left bank of the Rhine, 4 miles W. of the town of Neuss. A notable specimen of the transition from the round to the pointed style, was founded in 1299. Neuss has flourishing ironworks, foundries, flour and iron mills, and manufactures of cottons, woollens, leather, paper, chintz, &c. Pop. (1875) 35,563; (1885) 40,036; (1895) 25,026.

Neustadt, a town of Prussian Silesia, 25 miles S.W. of Oppeln. It is the seat of considerable industry, woollen and linen fabrics and carpets being the staple manufactures. Pop. (1875) 12,515; (1885) 16,093; (1895) 19,234.

Neustadt, or Wiener-Neustadt, one of the most beautiful towns of Lower Austria, is situated 32 miles S. of Vienna by rail. The town is overlooked by the large old castle of the Dukes of Hohenberg, now a military academy. The castle contains a fine Gothic chapel (1469), rich in painted windows; it is the burial-place of the Emperor Maximilian I. The old church dates from 1210, and was restored in 1860. A Cistercian abbey (1444) and a town-house are notable buildings. Locomotives and machinery, wire, bells, pottery, starch, leather, and ribbons are amongst the manufactures. The city, called 'the Ever-faithful,' was founded in 1112, and was rebuilt after a great fire in 1834. Pop. 23,738.

Neustadt-an-der-Hardt, a town of Rheinish Bavaria, at the foot of the Hardt Mountains, 20 miles W. of Spires. Its church, with several curious monuments, dates from the 14th century. It manufactures paper, cloth, soap, wine, brandy, &c. Pops. (1885) 6,133; (1890) 15,016.

Neustrelitz, capital of the grand-duchy of Mecklenburg-Schwerin, pleasantly situated in a hilly district, between two lakes, 62 miles N.W. of Berlin. Founded in 1733, it is built in the form of an eight-rayed star, and contains the ducal palace, with magnificent gardens. Pop. 9368.

Neustria, the name given in the times of the Merovingians and Carlovingians to the western portion of the Frank empire, after the quadruple division of it which took place in 511. Neustria contained three of these divisions. It extended originally from the mouth of the Seine to the Loire, and contained Aquitania on the S. and by Burgundy and Austrasia (Francia Orientalis) on the E. The principal cities were Soissons, Paris, Orleans, and Tours. See the historical maps at Europe.
Neutral Salts. See SALTS.

Neutrality. Neutrals are states which in time of war take no part in the contest, but continue to enjoy the benefits of belligerent commerce and war. The aim of the doctrine of neutrality is to reconcile the right of belligerents to carry on their warlike operations with the no less undeniable right of other nations to pursue peacefully their ordinary business. For many years after the rise of modern international law the conduct of warfare was discussed only with reference to belligerents, and no intermediate relation between an ally and an enemy was recognised. Not, indeed, till the middle of the 18th century did the terms 'neutral' and 'neutrality' come into general use; for not till then was a systematic effort made to regulate the relations of belligerents to nations standing aloof from the war, or to define their reciprocal rights and duties.

As between belligerent states and neutral states, the principles whence the complicated rules of modern neutrality are in themselves extremely simple. On the one hand, the neutral, being neither judge nor party, must show absolute impartiality in his dealings with both belligerents; on the other hand, the belligerent must pay scrupulous respect to the sovereignty of his neutral neighbour. Accordingly, throughout the war, neutrals continue diplomatic intercourse with both belligerents. A neutral state is not permitted to give armed assistance to either belligerent, even though such aid may have been promised before the war; nor to lend money to either party such loan; nor to allow the passage of belligerent troops through its territory. A neutral is bound to prevent and cancel all acts of hostility, either in the neutral territory itself or in the adjacent waters, and to prohibit the exercise of any belligerent jurisdiction therein. If, as an attempt be made by troops of either belligerent country to traverse neutral territory, the neutral state is bound to disarm and intern such troops, and to set at liberty all prisoners of war found within its borders. Should a neutral state deviate from its duty in any of these particulars, the war then ended is entitled to treat such deviation as a just cause of war. On the other hand, a belligerent is not permitted to carry on hostilities within neutral territory; nor to use neutral harbours for the purpose of fitting out expeditions against his enemy. He must scrupulously observe all the regulations of the neutral state regarding the admission of cruisers or prizes into their ports.

The relations of belligerent states to the private citizens of neutral states involve greater difficulties. On land the property of neutral individuals is, of course, protected from belligerent attack; but this rule an exception is furnished by the Right of Angary (Low Lat. Angaria, 'forced service'), under which a belligerent may seize the property of a neutral found in the territory of the other belligerent for the use of it for the purpose of warlike operations, subject to his paying compensation. At sea, however, the commercial interests of belligerent and neutral merchants are so interwoven that it is difficult to separate them and strike at an enemy without injuring a friend; hence the belligerent is allowed considerable latitude in his dealings with neutral goods on hostile ships were liable to confiscation, while hostile goods on neutral ships went free. By the other principle, the nationality of the property determined its liability, so that neutral goods went free even though found on hostile ships, while hostile goods were liable to seizure even though found on neutral ships. In 1856 the Declaration of Paris finally settled the question by providing (1) that the neutral flag should cover an enemy's goods, except contraband of war; (2) that neutral goods, except contraband of war, should not be liable to capture even under the enemy's flag. The law, as thus settled, is the old rule, 'Free ship, free goods,' without the corollary, 'Hostile ship, hostile goods.' Attempts had frequently been made at an earlier period, particularly by Prussia in the Silesian Loan controversy of 1750 and 1756, to incorporate the rule into international law. It was, indeed, mainly through the opposition of Great Britain that its final acceptance was postponed till 1860. To the general rule of maritime capture, as thus determined, several important exceptions must be noted. Belligerents continue to have the right of intercepting, even on board of neutral vessels, such articles as are deemed contraband of war. The test to be taken in deciding what goods are contraband has been much discussed and is not yet quite settled (see CONTRABAND). The vessel, too, carrying the goods may be condemned along with its contraband cargo, where both belong to the same owner, or where false papers are found, or any other fraudulent device is resorted to. Another instance in which a belligerent is entitled to interfere with the ships and property of neutral individuals is furnished by the law of blockade (see BLOCKADE). Again, if during a war ships belonging to neutral citizens perform certain classes of services on behalf of one of the belligerents, the other belligerent is entitled to confiscate these ships. Among such hostile services, against which a belligerent is entitled to protect himself, are reckoned the transmission of naval signals or messages, the carriage of military and naval despatches, and the transportation of belligerent officers or troops. When a citizen of a neutral state engages in any forbidden ventures—whether it be carrying contraband goods, running a blockade, or doing other un-neutral service—the aggrieved belligerent does not complain to the neutral state, but strikes at the neutral citizen directly by capturing his property and condemning it in his own prize court. But neutral citizens are only made liable to the matter at all, unless the penalty imposed by the prize court be such as is not warranted by international law; in this case the neutral state claims reparation for its injured subject from the offending belligerent.

The most unsettled part of the modern law of neutrality is that dealing with the obligations, imposed on a neutral state, of restraining the conduct of its own citizens and of enforcing the due observance of neutrality on all persons within its jurisdiction. In recent times the tendency has been to extend a large extension of the obligations of neutral states in this respect. The movement was commenced by the Neutrality Act of the United States, passed in 1794, and re-enacted, with additions, in 1818. The principles of these American statutes have been closely followed in the series of British laws on the subject. In view of arming the British government with sufficient power to enable it to fulfil the extended obligations of neutrality. Among the more important offences against neutrality which are now struck at by the municipal law of most states are such acts as the practice of arms, in considerable numbers for the purpose of enlisting in the service of a belligerent; to accept letters of marque from a belligerent; to fit out within its
NEVILLE

NEVADA

territory armed expeditions against a belligerent, or increase therein the warlike force of any belli-
gerent ship or expedition. At the same time a
neutral state is not bound to restrain its subjects
from such proceedings, nor to forbid the vessel
being armed, for the purpose of commencing hos-
tilities at the moment of its leav-
ing neutral waters. But the events connected
with the escape of the Alabama (see ALABAMA
and her sister-cruisers during the American civil
war showed the inadequacy of this view. The
Treaty of Washington, 1871, by which all these
questions were referred to arbitration, directed the
arbitrators to apply, in addition to the ordinary
rules of the law of nations, three new rules, known
as the Rules of Washington. These rules, owing
to their loose phraseology, have raised more ques-
tions than they have solved, but their general
effect is immensely to extend the duties of neutral
states.

See Hall, International Law (2d ed. 1884) and The
Rights and Duties of Neutrals (1871); Wheaton, Inter-
national Law (4th ed. 1881); and The Law of
Neutrality, for the history of the growth of the law of
neutrality, see Manning, Law of Nations. See also the Letters of
Historians, and the works cited at Enemy.

Neville, Alphonse Marie de, the most
popular of the younger school of French painters
of battle-scenes, was born at St. Omer on 31st May
1836, and after studying under Delacroix painted
a series of successful pictures illustrative of French
exploits in the Crimean war, Italy, and Mexico.
Then came the war with Germany. Neville fought
in the Lorraine and learned the elements of real
warfare from actual experience. This knowledge
imparted additional power to his next and last
series of works, depicting incidents of that war.
The attack at Ronke’s Drift and that at Tel-el-
Kebir were also chosen by him as subjects for
personal campaigns, which, when he laid down a
treaty of books, his best work in this line being
the designs for Guizot’s Histoire de France. He
died in Paris, 29th May 1885.

Nenwied, a town of Prussia, on the right bank
of the Rhine, 8 miles below Coblenz, was capital of
the mediatised principality of Wied; the castle of
which contains a valuable gallery of antique
Roman antiquities discovered here. The
town contains an important institute of the
Moravian Brethren, and there are some minor
manufactures. Pop. 9656.

Nev, a river of Russia, flows westward from
the south-west corner of Lake Ladoga to the Bay
of Kronstadt, in the Gulf of Finland, passing
through the island, St. Petersburg, and carries
several enormous volumes of water (greater than that of the
Rhine) from the lakes Ladoga, Onega, Ilmen, and others. Its
total length, with windings, is about
40 miles; in places it is over 4000 feet wide, else-
where the channel is narrowed to 180 feet; and in
one or two places the navigation is embarrassed by
reefs and rapids. It is frozen on an average from
November 25 to April 21. By the Ladoga Canal
the Neva communicates with the vast water-system
of the Volga, and thus it may be said to join the
Baltic with the Caspian Sea.

Nevada, a silver-mining state of the
American Union, bounded on the North by Oregon,
Utah and Arizona, and S. and W. by California. Its
greatest extent from north to south is a
length less than 500 miles, and its greatest width
from east to west is more than 300 miles. In area
(110,700 sq. m.), it is the fourth largest state of the
Union; in population it is the lowest of all the states
and territories—(1870) 42,491; (1880) 45,701;
(1890) 42,283. Nevada is included in the Basin
and Range region of the Great Basin (q.v.), once occupied
by a great inland sea, and afterwards by several great
lakes which have also disappeared. Some of the
depressions of such a body of water are yet
marked by Walker, Humboldt, Carson, Pyramid,
and Winnemucca lakes, and by other 'sinks' or
playas. The ancient shore-lines are clearly visible
in certain places, and the climate, now arid and
nearly rainless, was once moist. The soil of the
Great Basin at some time produced an abundant
vegetation, whereas it is now almost totally unfit
for agriculture, crowned upon by barren treeless
mountains, and traversed by regions of nearly
absolute desert. At present Nevada is a high
plateau with an average altitude of 4000 feet,
crossed by numerous ranges of mountains which as
a rule are parallel and separated by valleys from
5 to 20 miles in width. Some of these valleys are
barren and desolate; others, through which the
rivers flow, have areas of arable land. The
mountains contain rocks of every geological period;
many of them are volanic, and there are striking
geocratic exhibitions of those of ancient de-
ger. In the valleys lie the sedimentary deposits of ages
mixed with cinders and other volanic products
which fell in many coves on the surface of the
extinct lake, and at the mouths of the caños are
vast moraines. The mineral production of Nevada,
especially of silver, has been enormous (see Com-
stock LODE). Though the high grades of ore
appear to have been largely exhausted, the prod-
cution was at first so great as to materially change
the value of the precious metals, and to promote
Nevada hastily from an uninhabited desert to a
state of the Unions. Mining is still the chief
interest. A small area in the north is drained by
the Owyhee River, a tributary of the Snake, and
another portion of the state in the south belongs
to the Colorado valley. Otherwise Nevada lies
chiefly in the great basin of interior drainage,
where none of the great rivers reach the
sea. Many streams disappear in the sand or flow into 'sinks',
salt or brackish lakes, or playas, which are shallow
lakes that evaporate when the supply of water
fails. The Humboldt River pursues a winding course of 500
miles. The springs and salt lakes, many of which are surrounded with
irrations of tufa often in weird and fantast
c forms. Some of the lakes are nearly saturated
solutions of borax and salts of sodium and potas-
sium, and in the valleys are tracts of glistening
alkaline deposits, which mark the beds of extinct
lakes.

The atmosphere is dry, remarkably clear in
winter, but filled in summer with minute particles
of dust, which produce endless and extraordinary
effects of colour on the sunlight. The temperature
is subject to great extremes, and the climate is
chiefly light. It nowhere exceeds 15 inches, and
scarcely averages more than 5 inches. Some
sections receive no rain for several successive years.
Sage-brush and other desert plants capable of
enduring drought form the native vegetation. It
has been estimated that about three per cent. of the land may be successfully
cultivated. The Mormons established a few
permanent camps in 1848, and in 1850 a settlement
was made at Genoa; but the real history of the state
begins with the discovery of silver in 1859. Nevada
was separated from Utah territory in 1861, and in
1864 was admitted to the Union as a state. There
are fourteen counties in the state, and the most
important towns are Virginia City and Gold Hill,

Copyright 1910, 1911 and
1910 in the U. S. by J. B.
Lippincott Company.
which are contiguous and situated on the Comstock ledge and Carson, the capital. Within the state there are over 600 miles of railway. The state board of education controls the public schools; there is a state university at Reno. In 1898 there were 85,299 Indians (Pah-Utes, Pi-Utes, and Shoshones), living on 1,400 sq. m. of reservations. The schools on the reservations are well attended.

**Nevers,** the capital now of the French department of Nièvre, and formerly of the province of Nevers, is picturesquely seated on a hillside, 600 feet above sea-level, at the influx of the Nièvre to the Loire, 159 miles by rail SSE. of Paris. The *Niéronum* of Cesar, it has been the seat of a bishop since 506; its beautiful cathedral, restored in 1758, belongs mainly to the 13th century. The stately *palais de justice,* dating from 1455, was formerly the castle of the Dukes of Nevers; and there are also a fine public garden, a bridge of fourteen arches over the Loire, a medieval gateway, and a triumphal arch (1746) commemorating Fontenoy. The industries comprise the manufactures of damask and velvet, damoison, porcelain (introduced by Italians about 1565), &c. Pop. (1872) 22,276; (1886) 23,610; (1896) 24,750.

**Neviansk,** a town of Russia, in the government of Perm, 50 miles N. of Ekaterinburg by rail, stands on the Siberian side of the Ural Mountains, and on a tributary of the Tobol. The district around Neviansk is famous for its mineral wealth, particularly gold and iron. Pop. 16,066.

**Neville's Cross.** See Bruce (David).

**New,** an island of the West Indies, belonging to Great Britain, forms one of the Leeward Islands, and lies 2 miles SE. of St Christopher, with which it has been since 1822 administratively connected, sending three (unofficial) members to the common legislative council. It is circumscribed in form, rises in the centre to a wooded ancient crater (3200 feet), and has an area of 50 sq. m. The lower slopes are cultivated, the sugar-cane being the principal crop, though limes and oranges are grown to a small extent. Statistics are given under St Christopher (p. 1503). Pop. (1891) 15,087. The capital is the port of Christiansted (p. 1500). New Amsterdam was discovered by Columbus in 1498 and colonised by England in 1625. As long as the slave-trade lasted it was one of the principal markets for slaves in the West Indies. The island has suffered much at various times from hurricanes and earthquakes.

**New Oldbury.** See Nevers.

**New Albany,** capital of Floyd county, Indiana, is on the north bank of the Ohio River, nearly opposite Louisville. By rail it is 317 miles S. by E. of Chicago and 267 miles E. of St. Louis. The city is well built, and is the principal manufacturing town in the state. It contains iron and brass foundries, rolling mills, potteries and brick-yards, flour, woolen, cotton, and planing mills, &c.; while its plate-glass works are the largest in the United States. Pop. (1880) 16,423; (1900) 20,028.

**New Almaden.** See Almaden.

**New Amsterdam.** See New York.

**Newark, (1)** a port of entry and the capital of Essex county, New Jersey, is on the Passaic River, 9 miles by rail W. of New York. It is a handsome city, with beautiful parks and wide streets shaded with lines of elms. It has a city hall, court-house, public library, and nearly 150 churches, but is mainly noteworthy for its manufactures. There are altogether 400 industrial establishments in Newark, producing brass and copper ware, and shoes, iron and steel in large quantities, and among its manufactures, Pop. (1890) 40,733; (1900) 62,442.

**Newbern,** a town and port of entry, capital of Craven county, North Carolina, is situated at the junction of the navigable Neuse and the Trent (here crossed by a long bridge), 107 miles by rail NE. of Raleigh. It exports tobacco and lumber, and early vegetables for the North. It manufactures railroad-cars and cotton-seed oil, and has also a wood-pulp factory, sawmills, and an oyster-canning establishment. Pop. (1900) 6900.

**Newkirk.** See Nott's, a town of Ontonagon county, Michigan, on the Michigan Central railway. Pop. (1880) 26,845; (1890) 40,733; (1900) 62,442.

**Newkirk.** See Nott's, a town of Ontonagon county, Michigan, on the Michigan Central railway. Pop. (1880) 26,845; (1890) 40,733; (1900) 62,442.
NEWBURY

J ohn, a London bookseller, intimately associated with Dr Johnson, Goldsmith, Christopher Smart, Smollett, and many other men of letters, was descended from an old bookselling family, and born a farmer's son, in the Berkshire parish of Waltham St Lawrence, about midsummer 1719. He had first a shop for general wares at Reading, and about 1744 settled in London as a vocalist, and sold music. His system of letters was so successful that many of the Melanesian division are warlike, but suspicious and crafty. They make handsome canoes, with sails and outrigger sails, earthenware vessels, baskets, nets, &c. The sling, stone axe, and spear are their favourite weapons. They worship gods, and are Hindus. Area, 9390 square miles.

The population of the several islands is not known.

See Remilly, The Western Pacific and New Guinea (1886); Powell, Wanderings in a Wild Country (1883); and Parkinson, In Bismarck-Archipel (1887). For map, see New Guinea.

NEW BRUNSWICK

a province of the Dominion of Canada, is bounded on the N. and NW. by the province of Quebec, from which it is separated by the river Restigouche; on the N. by the Chaleur Bay; E. by the Gulf of St Lawrence and Northumberland Straits—the latter separating it from Prince Edward Island, 19,007; and on the W. by the state of Maine, the boundary with the latter being the St Croix and St John rivers. It has an area of 28,200 square miles—rather smaller than Scotland. Its coast-line is 500 miles in length, interrupted only at five points by the natural harbours of the St John and the Chaleur Bay and port of Nova Scotia; and on the W. by the state of Maine, the boundary with the latter being the St Croix and St John rivers. It has an area of 9390 square miles. Several important rivers traverse the province; among the principal is the St John, 450 miles in length, and navigable for vessels of 100 tons to Fredericton, the capital of the province, 90 miles from the sea. Above this point smaller vessels and steamboats ascend 18 miles of the Chaleur Bay and port of Nova Scotia, which are drained by the St John and its tributaries comprises about nine million acres in New Brunswick, as well as eight million in Quebec and the state of Maine. The Miramichi River, 220 miles long and 7 miles wide at its mouth, is also navigable for some distance. The Restigouche River, 104 miles wide at its entrance into the Chaleur Bay, and over 200 miles in length. The lakes are numerous, but of small extent, the largest being Grand Lake, 30 miles long and 7 miles wide, communicating with the St John River, 90 miles from the sea.

The population of the province in 1881 was 321,270; in 1919 321,270. In 1919 there were 115,961 Catholics, 75,649 Baptists, 43,093 Church of England, 40,639 Presbyterians, and 35,504 Methodists. The population in 1881 included 38,287 persons of English origin; 101,284 Irish; 49,829 Scotch; 1401 Indian; 6310 German; French, 56,335. The principal cities and towns are St John (including Portland), (44,000), Fredericton, the capital (7000), Moncton (6000). The provincial government is administered by a lieutenant-governor, and is made up of an executive council of eighteen, and a legislative assembly of forty-one members, elected by the people. The province sends ten members to the senate, and sixteen to the Dominion House of Commons.

Like that of many other parts of Canada, the climate of New Brunswick is subject to extremes of heat and cold. The mean temperature for the year 1885 was 40°3 F. at St John; the highest and lowest temperatures for the year being 81° and -15° respectively. If, however, the climate of a country is to be judged by its effects on animal
life, that of New Brunswick may be pronounced one of the best in the world.

The revenue is largely made up of subsidies from the Dominion government and from what is called 'the old industry,' including the proceeds of land and timber sales. The educational institutions supported by law are the Provincial University, the training or normal school for teachers, and a complete system of free common schools.

The provincial revenue in 1880-85 was about $75,000,000, most of it coming from revenue from the government property. The imports have a value of about $7,000,000, nearly half from the United States. The exports reach a somewhat higher value, timber being the chief item. The fisheries of the Bay of Fundy, as also the river fisheries, are very valuable.

Attention has been paid to live-stock both by the government and private breeders, and recently the government has established a stock farm. The province, owing to its cheap coal and proximity to the markets of the world, has also many advantages as a manufacturing country. The principal articles manufactured are sawn timber, leather, cotton and woollen goods, hosiery, woolen, iron and brass foundries, and manufactories of saws, needles, paper hangings, &c. Pop. (1900) 20,000.

Newburgh, a royal burgh of Fife, near the Firth of Tay, 11 miles ESE. of Perth. It arose in connection with the neighbouring Benedictine abbey of Dunkeld and the provostship (now vacant) of which the priory is the chief industry. It contains a Roman Catholic cathedral, and nearly a score of other churches, and is the seat of Rintger's College (1771), connected with which is the theological seminary of the Dutch Reformed Church, as well as an observatory and a private agricultural college and model farm. Newburgh is a large and important town, and has many woolen, cotton, and woolen and cotton goods and other factories, and has also iron and brass foundries, and manufactories of hosiery, lamps, needles, paper hangings, &c. Pop. (1876) 3474. See A. Laing's Lindores and Newburgh (1876).

Newburgh, a city of Orange county, New York, is on the west bank of the Hudson (here 11 mile wide), 57 miles by rail N. of New York, amid the grand scenery of the Highlands. Its handsome edifices, villas, and gardens, rising 300 feet from the river, command a noble prospect. The city has, besides foundries, boiler-works, shipyards, and powder-mills, manufactories of woolen and cotton goods and carpets, leather, flour, soap, oil-cloth, brushes, paints, plaster, tiles, &c. Large quantities of butter, grain, and provisions are shipped here. Newburgh was the scene of the disembarkation of the American army, 23d June 1783; and 'Washington's Headquarters' is preserved as the property of the state. Pop. (1900) 24,943.

Newbury, a thriving market-town of Berkshire, on the 'swift' Kennet, 17 miles W. by R. of Reading and 55 from London. Its grey old church, restored in 1807 at a cost of £15,000, is a fine Perpendicular edifice, with a noble tower added in 1510 by John Winclescombe or Smallwood, otherwise 'Jack of Newbury,' a famous clothier, who sent a hundred of his own men to fight at Flodden. The large Italian corn exchange was built in 1826, in which year was started a great yearly wool-market; and still more recent are the handsome municipal offices and the new grammar-school, though this claims King John for its founder (1216). Newbury—'new only as distinguished from the old Roman station of Sobres (now Speen)—besides has many ancient and wealthy charities. It was incorporated by Elizabeth in 1506, and the borough boundary was extended in 1878. Pop. (1851) 6574; (1881) 10,144; (1891) 11,002. Two hard-fought battles took place here in the Great Rebellion—the one between Clariers and Essex, on 29th September, 1643; the other between Charles and Manchester, on 27th October 1644. The advantage of the first was, on the whole, on the side of the king, but it cost the lives of Lords Falkland (q.v.), Carnarvon, and Sunderland, to whom a memorial was erected in the church. The second would have been a decisive royalist defeat but for Manchester's hesitancy.

See the History of Newbury (1839), a work on the two battles by W. Money (1881), and his History of the Ancient Town of Newbury (Oxford, 1887).

Newburyport, a city and port of entry of Massachusetts, on the south bank of the Merrimac, 3 miles from its mouth, and 37 miles by rail NE. of Boston. A long, shady High Street, with a pond of six acres, is its chief ornament. Shipbuilding is carried on, and there are a number of large cotton and shoe factories, besides manufactories of cotton goods. The town was settled in 1720, but died in 1770, is buried. Pop. (1900) 14,478.

New Caledonia, an island of the South Pacific Ocean, belonging to France, and lying midway between the Fiji Islands and the east coast of Queensland. The Loyalty Islands, Isle of Pines, and some others, with a total area of 1290 sq. m., are politically dependent upon New
Caledonia. This principal island is about 240 miles in length, 23 in average breadth, and has an area of 6430 sq. m. The long axis runs from north-west to south-east; the interior is greatly broken by irregular mountain-chains (highest point, Mount Humboldt, 5390 feet); and the entire island is surrounded by coral-reefs. There are good harbours here, but amongst which has been used St Nomena, the capital (4601 inhabitants), on the south-west coast. In the valleys the soil is fruitful, producing the cocoa-nut, coffee, maize, tobacco, fruits, &c. But the most valuable natural products are minerals, especially nickel, with copper, gold, and antimony. The island is largely used for valuable timber-trees. Promising attempts have been made to introduce wheat, the vine, and the silkworm. Turtle and fish are abundant. Locusts frequently devastate the crops. Besides the smelting of the minerals, meat is preserved and sent to France, and some soup and tabbouleh are manufactured. Wines and spirits, flour, drapery, groceries, ironmongery, machinery, coal, &c, are imported to the annual value of £400,000, and nickel, cobalt, chrome ore, silver, lead ore, preserved meat, copper, coffee, &c, are exported, to the value of £390,000. Every year about 130 vessels of 75,000 tons visit the island, one-half being British. The total population in 1890 numbered 62,790, thus made up—aborigines (Cancaques), 41,884; French colonists, 3593; convicts, 7487; liberated convicts and political prisoners, 2221; officials and others, 3478. The island was discovered by Captain Cook in 1774, and was annexed by France in 1833. She began to use it as a convict station, and after 1871 sent out great numbers of political prisoners, mostly Communists. The aborigines are a mixture of two types, one resembling the Polynesians, the other the Papuans. They were formerly cannibals, and delighted in war, yet were hospitable, and skilful tillers of the soil. They live now chiefly on chicken food. Leprosy is a scourge amongst them. See the French works on New Caledonia by Lemoine (1878 and 1884), Rivière (1880), Charter (1884), Cordell (1885), and Monceon (1888).

Newcastle, capital of Lawrence county, Pennsylvania, on the Shenango River, 50 miles by rail NW. of Pittsburgh, contains a college, large rolling-mills, foundries, and manufactories of nails, furnaces, and flour. Pop. (1890) 28,339.

Newcastle, port of Newcastle upon Tyne, NE. England, by rail, at the mouth of the Hunter River. It is the chief port of the north coast, its shipping nearly equaling that of Sydney; coal and wool are the main exports. The harbour, which is defended by a fort, is dangerous during storms from the ESE. Pop. (1881) 15,395; (1891) 12,914.

Newcastle, Dukes of. See Cavendish and Pelham.

Newcastle-under-Lyme, a parliamentary and municipal borough of Staffordshire, on the Lymne brook, 16 miles NW. of Stafford and 147 by rail NW. by N. of London. Pop. (1871) 17,493; (1891) 18,432. The aspect of the town has not in recent years been much improved by the widening of the main thoroughfares, and the erection of new public buildings, notably the town-hall (1890) and the high school (1876). The latter was reconstituted under a new scheme in 1874 from the amalgamation of various academies or preparatory schools (1862); a few distinctive features are the study of natural science and modern languages. The parish church, partly Early English and partly Decorated, was rebuilt in 1876 from designs of Sir Gilbert Scott, and has a quaint octagonal tower of red sandstone with pinnacles, and a fine peal of bells. The manufactory of hats was formerly a speciality of the town, but has of late years been discontinued; brewing, malting, and the making of paper and army clothing are now the principal industries, whilst the surrounding district is noted for its potteries, and numerous coal-mines are worked. Of the castles which it bears in its name, all traces have entirely disappeared; it was built by Edmund, Earl of Lancaster, the youngest son of Henry III. Newcastle, which confers the title of duke upon the family of Clinton, returned two members to parliament from 1333 to 1883, since which time it has returned one member only.

Newcastle-upon-Tyne, a city and county of itself, seated on the north bank of the Tyne, 275 miles from London, 117 from Edinburgh, and 10 from the German Ocean. It is the seat of a bishopric founded in 1882. The city is governed by a corporation consisting of a mayor, 10 aldermen, and 48 town councillors. It returns two members to parliament. Pop. (1801) 28,294; (1811) 71,550; (1821) 145,355; (1891) 186,345.

During the Roman occupation of Britain the high ground overlooking the river in the neighborhood of the castle was the site of the military station of Pons Elii, commemorated in the name of the town as Monkcastle. Pandon, which until 1299 was a vill or quitt leasold from Newcastle, is supposed to have been the place where, about 653, Penda, son of Penda, king of the Mid Angles, and Sigebert, king of the East Angles, were baptised by Bishop Finn. When the Conqueror arrived at the castle his horse was terried, and it is said to be seen of the bridge above water, and the town was too small or impoverished to victual his army. Robert Curthose, on his return from an expedition against Malcolm in 1080, constructed a fortress here, which was named the New Castle. The south-western is probably a fragment of his work. Will Rufus is stated—on doubtful authority—to have rebuilt the castle, and to have granted to the inhabitants of the growing town many privileges and immunities. He besieged the castle in 1065. The present keep—one of the most perfect examples of a Norman stronghold in the kingdom was built between 1172 and 1177 at a cost of £911, 10s. 9d., and the Great Gate of the castle—the Black Gate as it is now called—in 1247, at a cost of £314, 15s. 11d.

In the time of the first three Edwards the town was enclosed by a wall, 8 feet thick and over 12 feet high, which embraced in its circuit the monuments of the Black, the White, and the Grey Friars, the Benedictine nunneries of St Bartholomew, together with the vill of Pandon. The levies for the Scottish wars were usually directed to assemble at Newcastle, from which the battle which was declared for the king, was besieged for ten months by the Scots under General Leslie. This loyal resistance of the town to the forces of the parliament is commemorated in the motto which it bears on its coat of arms: Fortiter Defendit Triumphans. 14th century. In the 15th century the town were the visitations of the Asiatic cholera in 1831 and 1833, and the great fire which destroyed so much of the old town in 1854. The city occupies a striking and picturesque site, being built for the most part on steep slopes and gently rising ground. It abounds in contrasts, such as the grim old keep and the High Level Bridge; the modern Grey Street and the ancient Side; the stately stone buildings erected by Grainger and the half-timbered Elizabethan houses with projecting stories and latticed casements; the Elswick Works, a mile in extent, and Jesmond...
Dene, one of the loveliest ravines in the country; the closely-packed lillies and the rolling expanses of grass within it is a joy.

The principal remains of antiquity in Newcastle are the Norman keep; the Black Gate; the cathedral of St Nicholas; the churches of St John and St Andrew; portions of the Edwardian walls, with the Durham, Heber, Mordanl, and Plummer towers, and the Salt-port Gate, part of the Black Friars Monastery; fragments of the houses of the Austin Friars and the Friars of the Sac; and several mansions of the 16th and 17th centuries. The church of St Nicholas, now the cathedral, is said to have been founded by Osmond, Bishop of Shrewsbury (1301-1323). This magnificent structure was destroyed by fire in 1216. The present building belongs to the Decorated and Perpendicular periods; the nave and transepts dating from 1359, the chancel from 1368, and the tower with its beautiful architectural crown from about 1485. All that remains of the previous edifice is some masonry above the arcades, together with an Early English pillar built up in the north-east pier. The reedices, erected in 1888, is of fine unpollished Uttexeter alabaster with splayed screens of Caen stone. In canopied niches around the central figure of Christ are statues of Northumbrian saints and the four evangelists. St John's Church, built in the latter part of Henry I's reign, contains much of the original Norman work, with Early English, Decorated, and Perpendicular additions. St Andrew's Church dates from about 1175 to 1185, and retains some interesting Transitional features. All-Saints' Church was rebuilt in 1785-90 on the site of the church of All-Hallows, founded in the 12th century. There are twenty-one other places of worship in the city connected with the Established Church; the Roman Catholics have four churches, one being the cathedral of St Mary, erected in 1844 from the designs of Pugin; and the various other religious bodies are represented by about sixty chapels and meeting-houses.

The central part of Newcastle with its stately and ornate buildings is a monument to the genius of Richard Grainger (1728-1801), a man of lowly origin, who, by his vast building schemes, quite changed the appearance of his native town. Grey Street and Grainger Street, built in 1834-38, are the finest thoroughfares in the city. Monuments have been erected to Earl Grey (1838) and George Stephens, Esq. (1862). NEWFOUNDLAND

W. G. Armstrong, Mitchell & Co., Limited, founded in 1847. They comprise blast-furnaces, enginewrights, and foundries, and since the amalgamation of the original firm with that of C. Mitchell & Co., shipbuilders, at Walker, in 1882, several ships of war with their armaments have been completed at Elswick, a notable one being the Ill-fated H.M.S. Victoria. From the engine-works of R. Stephenson & Co. (founded by George Stephenson in 1824), and R. W. Hawthorn, Leslie & Co., locomotive and marine engines have been sent to all parts of the world. Newcastle is the birthplace of Lord Eldon and Collingwood, Mark Akenside, C. Chubb, Hutton the mathematician, and Lord Armstrong.

See Gray's Charvgesapher (1649); and the histories of the town by Bours (1736), Brand (1789), an anonymous writer—supposed to be the Rev. John Bailie (1801), E. Mackenzie (1827), Welford (3 vols. 1884-87), R. J. Charlton (1885), and J. R. Boyle (1890).

New-chwang, or Niu-chwang, a city of China, in the province of Manchuria, stands on the river Liao, 20 miles from its mouth and 120 from Mukden. By the treaty of Tientsin (1858) New-chwang was opened to foreign trade. From the accumulation of alluvial soil in the lower reaches of the river, the country is more yielding to agriculture and discharge at Ying-tzu, at its mouth. It is there the Europeans are settled, and they call Ying-tzu by the name of the treaty-port New-chwang—which latter is now a greatly decayed place. Ying-tzu imports cotton, woollen, and silk goods, sugar, paper, metals, opium, tobacco, &c., to the annual value of £600,000, and exports beans, silk, ginseng, skins, and horns to the annual value of £1,300,000.

The import of Indian opium has fallen from £275,000 in 1896 to £600. The port was captured by the Japanese in March 1895; in 1896 provision was made for connecting it with the Siberian railway; and by 1898 it was, like the rest of Manchuria (q.v.), almost wholly under Russian control. The port is closed four or five months from November with ice. Since 1872 Scottish Presbyterian missionaries have been working here; there is also a Roman Catholic mission. Pop. 60,000.

Newcomb, Simon, astronomer, was born at Wallace, Nova Scotia, 12th March 1835, graduated in 1858 at the Lawrence Scientific School, at Harvard, and in 1861 became a professor of Mathematics in the United States navy. He was appointed at that time to the observatory at Washington, and in 1877 was placed at the head of the office of the official American Ephemerides and Nautical Almanac. He organised the government expedition to observe the transit of Venus in 1874, and in 1882 observed the transit of the same planet at the Cape of Good Hope; he had already been sent to Saskatchewan (1890) and to Gibraltar (1750-71) to observe eclipses of the sun. In 1884 he undertook, in addition, the duties of the chair of Mathematics and Astronomy in the Johns Hopkins University. His writings cover over a hundred papers and memoirs, and include especially a most exact table of the motions of the planets. He has also published several volumes on political economy. Professor Newcomb is a Fellow of the Royal Society of London, and has received doctorates from Columbia University, Harvard, Leiden, and Heidelberg, and many other honours, both in America and in Europe.

Newcomen, Thomas, the inventor of a Steam-engine (q.v.), was born at Dartmouth sometime in the month of February 1663, and died in London in August 1729. In 1705, along with Cawley, a Dartmouth Sawyer, the manager of a Cornish mine, he obtained a patent for what is now known as the atmospheric steam-engine.

Some six years later his invention was brought into use for pumping water out of mines.

Newdigate, Sir Roger (1719-1806), was born and died at Arlington in Wiltshire, having sat for many years in parliament as member for Middlesex and the university of Oxford. He was a great antiquary, but now is chiefly remembered as the endower of the Newdigate prize poem at Oxford, winners of which have been Heber (1803), John Wilson (1804), Millman (1819), Hawiking (1827), Lord Seaborne (1832), Faber (1836), Stanley (1837), Ruskin (1839), Sharp (1842), M. Arnold (1843), Sir E. Arnold (1852), J. A. Symonds (1860), W. J. Courthope (1864), and W. H. Mallock (1871).

New England, a collective name given to the six Eastern States of the United States of America—Maine, New Hampshire, Vermont, New York, New Jersey, and Pennsylvania—embracing an area of 66,400 sq. m. The people, distinctively known as Yankees, are celebrated for industry and enterprise. The joint population in 1900 was 5,952,017; this is more than one-fourteenth of the entire population of the United States. New England is less than one-fifteenth of the total area of the United States. For the influence of the Puritans who settled here, see Fiske, The Beginnings of New England (1889).

Newent, an old market-town 8 miles NW. of Gloucester. Pop. of parish, 2838.

New Forest, a triangular district of south-west Hampshire, bounded by W. by the river Avon, S. by the Solent and English Channel, and E. by Southampton Water. It measures about 14 by 16 miles, and has an extreme area of 144 sq. m., or 92,363 acres, of which, however, only 64,292 belong to the crown domains. The rest, which, excluding those claimed from the earliest times; its present name dates from 1079, when the Conqueror here made a 'mickle deer-frith,' and cleared away several hamb- lets. This afforestation, enforced by the savage 'Forest laws, was regarded as an act of the greatest cruelty; and the violent deaths met by two of his sons, Richard and William Rufus, of whom one was killed here by a stag, and the other by an arrow, were looked on as special judgments. The deer were removed under an act of parliament (1851); and under another of 1877 the New Forest is now managed by the crown as a public pleasure-ground and cattle-farm. Enclosed plantations occupy about one-fourth of the entire area, the remainder being open woodland, bog, and heath. The principal trees are oaks and beech. The former were once much used as timbers for the navy; the mast of the latter still feeds large herds of swine. There is also a herd of small, rough-coated ponies. The holies, the rhododendrons, and therewith the general absence of under-wood, give a beautiful park-like aspect to the forest, points within which on whose area are Lyndhurst, Beaulieu, and Lymington.

See Gilpin's Forest Scenery (ed. by F. G. Heath, 1879); Blackmore's Crockodow Nowell (1896); and Wise's The New Forest (1883; 4th or 'Artist's edition,' 1883, with Linton's engravings of views by Crane, and etchings by Sumner); The Portfolio (1884); The New Forest by De Crespy and Hutchison (1885); also Forest Laws.

Newfoundland (New-foundland), an island and British colony in North America, not yet incorporated with the Dominion of Canada, lies at the mouth of the Gulf of St Lawrence, separated from Labrador by the strait of Belle Isle (q.v.), 11 miles broad), and extending in lat. from 46° 38' to 51° 37' N., and in long. from 52° 44' to 50° 30' W. In shape it resembles an equilateral triangle, of which Cape Bauld on the north, Cape Race on the south-east, and Cape Ray on the...
NEWFOUNDLAND

The industry of canning lobsters, though commenced in 1860, has an annual value of about $500,000. Some 25,000 to 35,000 tons of lobsters have been erected by the French upon the coasts of Newfoundland over which they have certain rights, but the legality of this contest is contested by the colonists, upon the ground that its lobstering is a 'fish' but a crustacean, and that canning lobsters is not catching them. The average annual value of the herrings exported and consumed in the country is about $650,000, and that of the salmon exported about $100,000.

The people chiefly depend for a livelihood upon the production of cod-fisheries, which are the three distinct branches—namely, the Labrador fishery, the shore fishery, and the bank fishery. The average annual value of the cod-fishery is $6,034,242. This calculation includes the dried cod-fish exported, the quantity consumed by the population, and the oil extracted from the fish. From 25,000 to 35,000 people and 1200 vessels engage in the Labrador fishery, and the annual export is valued at about $1,500,000. The shore fishery is prosecuted along the whole coast-line in Newfoundland, and is the mainstay of the very large portion of the population who from poverty, age, or disability are unable to live on either the Labrador or bank fishery, or divide their time between farming and fishing. The bank fishery is prosecuted upon the 'Banks,' so called, which lie to the southwards of Newfoundland. These 'Banks' are submarine platforms extending over a tract of water 600 miles in length and 200 miles in breadth. The depth of water over the 'Banks' varies from 100 to 600 feet, and the most productive ground is known as the 'Grand Bank.' American, Canadian, and French fishermen also resort to these 'Banks' from St. John's to the Grand Bank, the islands, St. Pierre and Miquelon, as a base of operations.

But it is necessary to procure fresh supplies of herring, caplin, and squid at frequent intervals for use as bait upon the 'Banks,' and this can only be obtained, at the seasons when most wanted, and without great delay or expense, in the southern bays of Newfoundland, chiefly in Fortune and Placentia bays. Newfoundland does not now allow the bait-fishes to be exported for bait except under licenses, for which a large fee has to be paid, and the result has been a considerable decrease of the catch on the 'Banks.'

The revenue in 1893—the year before the great financial, commercial, and political crisis—was $1,853,844, the expenditure being $2,110,000, while the debt in 1894 was $9,116,334. The imports in some years have reached $7,300,000, the exports $8,300,000. There has been a slow recovery since 1894, assisted by very promising finds of gold during the year 1896.

In 1882 a contract was made with a company for the construction of a railway from St. John's to Hall's Bay, a distance of about 250 miles. After the construction of the railway—about 1885—Stop the Grace—had been completed the work of construction was suspended. In 1887 the government completed a branch-line to Placentia. By the 'Reid contract' (1898) a private contractor leased the railways from government for fifty years, agreed to work them, and completed a railway from Conception Bay to the grant of so much land per mile, undertook to make docks and build steamers for a fast route to Britain (Galway or other port), and arranged to exploit the coal and iron of the interior. Atlantic cables land at Heart's Content, on the eastern side of Newfoundland, and grow under the western side. There are 140 miles of telegraph.

The early history of Newfoundland is involved in obscurity. It was discovered 24th June 1497,
in the reign of Henry VIII, by John Cabot, and the event is attested by the following entry in the accounts of the privy-purse expenditure: '1497, Aug. 10, To hym that found the New Isle, 10.' It was visited by the Portuguese navigator, Gaspar de Cortereal, in 1500; and within two years after that time regular fisheries were established on its shores by the Portuguese, Biscevians, and French. In 1578, 400 vessels, of which fifty were English, were engaged in the fishery. Sir Humphrey Gilbert (q.v.), with his ill-fated expedition, arrived in St John's Harbour, August 1583, and formally took possession of the island in the name of Queen Elizabeth. In the return voyage the expedition was scattered by a storm, and the commander lost. In 1621 Sir George Calvert (afterwards Lord Baltimore) settled in the great peninsula in the south-east, and named it the Province of Avalon. The history of the island during the 17th and part of the 18th centuries is little more than a record of rivalries and feuds between the English and French fishermen; but by the treaty of Utrecht (1713) the island was ceded wholly to England, the French, however, retaining certain privileges in connection with the fishing and drying of fish on the coasts extending from Cape Bonavista on the east to Point Riche on the west. By the treaty of Versailles (1783) the boundaries were so changed as to extend from Cape John on the east to Cape Ray on the west, and at the same time the French were permitted to fish thereon in some places in the competition of the British. This promise the French construed and urged so as to prevent the development of the resources of the interior adjacent to coasts over which their rights extend, and much friction consequently exists between the French and St. John's residents. A resident government was appointed in 1728. The present form of government, established in 1855, consists of the governor, an executive council, or cabinet of seven members, a legislative council of fifteen members (appointed by the crown), and a general assembly of thirty-six members (elected by the people). Every man of twenty-one years of age, a British subject and two years a resident in the colony, is entitled to vote at elections.

Fraser Rae, Newfoundland to Manito a (1881); Murray and Howley, Geological Survey of Newfound land (1881); Hatton and M. Harvey, Newfound land: The Province Beautiful (1888); and English Treaty Rights (1890); Harvey, Newfound land as it is in 1894; Prowse, A History of Newfoundland. For map, see CANADA.

Newfoundland. A breed of dogs originally introduced into England from the island of New findland, where they were used for draught purposes. As the mastiff at that time was scarce, and the St. Bernard had not yet appeared in England, the Newfoundland became exceedingly common, but has been eclipsed in popularity of late years by the other two breeds mentioned. In general appearance the Newfoundland is a large and imposing dog, mild in expression, but showing great strength. The head should be large, with ears falling close on the neck long, if possible; loins strong and well ribbed up, a point seldom seen in this breed; tail long and powerful, as it is used greatly when swimming; coat, long and wiry; colour, black without any distinctive markings. Much discussion was caused by Sir E. Landseer's well-known picture of a black and white dog entitled 'A Distinguished Member of the Humane Society' (1838). An attempt was made to prove that the black and white dog was the true Newfoundland; but it is now generally regarded as a cross from the black. The black and white variety, now known as the Landseer Newfoundland, has been kept pure for many generations; it is now almost as rare, and certainly as handsome, as the original variety. The Newfoundland is a splendid water-dog, and takes to the sea at an early age. He is also a natural retriever, and, though himself too heavy for field work, has been extensively used to found the ordinary retriever. From his formidable appearance, combined with docility and intelligence, he makes a capital watch-dog, for which purpose he is extensively used.

Newgate, a celebrated London prison, stands at the western extremity of Newgate Street, opposite the Old Bailey. The exterior presents high dark stone walls, without windows. It was long the chief criminal prison of city and county, but is no longer used for prisoners to be tried at the Central Court, and is in the hands of the Court of Aldermen. The earliest prison here was in the portal of the new gate of the city as early as 1218; and hence the name. About two centuries afterwards it was rebuilt by the executors of Sir Richard Whittington, whose statue with a cat stood in a niche, till its destruction by the great fire of London in 1666. The present edifice was erected in 1780, but the new buildings were greatly damaged by fire in the Gordon Riots of that year (see Roswell's Johnson under that date), when 500 prisoners, felons as well as debtors, were released and let loose upon the public. This awful scene is described by Dickens in Barnaby Rudge. After the passing of the Prisons Bill in 1877 Newgate, being considered a very costly and redundant establishment, was gradually disused, and is now, except during sessions or when the gallows is in requisition, practically closed. The Newgate Calendar contains biographical notices of the most notorious murderers, burglars, thieves, and forgers who have been confined within its walls. See Griffiths, Chronicles of Newgate (1884).

New Granada. See COLOMBIA.

New Guinea, an island of Australasia, the largest in the world except the Australian continent, from which it is separated by the shallow island-studded Torres Strait, 80 to 90 miles wide at its narrowest part, about the meridian of the York Peninsula. There is now no doubt that the two regions at one time, probably during the Miocene epoch, formed continuous land, and an upheaval of less than sixty fathoms would suffice again to unite them. The human line, as determined by Wallace, would also include the insular groups of Jobi, Biak, Suk, Mafar

Newfoundland Dog—Bismarck, 1890.
(Nuford), and Ambervo in Geelvink Bay; Aru, near the south-west coast; Myol, Salwatty, Banu, and Wajjin at the north-western, and the Louisiade and D'Entenrcausten Archipelagoes at the south-eastern extremity of New Guinea. But elsewhere the mainland is washed by deep waters, ranging from 500 to 1300 fathoms on the south-eastern and northern coasts. It is disposed in the direction from north-west to south-east, stretching from Cape Goede Hoop ('Good Hope'), just south of the equator (0° 19' S. and 132° 39' E.), for about 1500 miles to South Cape, over 700 miles below the equator (10° 34' S. and 150° 43' E.). But owing to its extremely irregular shape, somewhat in resembling a huge saucer, the width varies from under 20 miles at the narrowest parts of both extremities to 480 miles at the broadest part, about 144° E. long., giving a total area roughly estimated at 320,000 sq. m., or six times as large as England. The island thus forms three somewhat distinct geographical divisions—a large central mass from which two peninsulas project south-east and north-west. The south-east peninsula is defined by Huon and Papua Gulfs on the north and south coasts, while the north-west peninsula is decomposed into two secondary members by the Macleay Inlet, which penetrates from the south-west side to within 20 miles of Geelvink Bay on the north-west coast.

Most of the interior is still a terra incognita; but the more salient physical features of the island have already been roughly determined. It is essentially a mountainous and even an alpine region, being traversed in its entire length by lofty ranges, by far the highest in the Oceanic world, and in some places rising 2000 or 3000 feet above the snow-line. These ranges, which in the two peninsular regions form single continuous systems, develop in the broader central parts two or more parallel chains with a general south-easterly trend, at many points approaching close to the coast-line, and elsewhere enclosing extensive rugged plateaux. Thus, the Arfak Hills of the north-west peninsula (10,000 feet) are continued in the central region by the Charles-Louis range, which for nearly 300 miles appears to maintain an altitude of over 14,000 feet, with many peaks towering to heights of 18,000 and even 20,000 feet. Parallel with this chain runs the northern coast range, known as the Finisterre Mountains (11,000 feet), which terminate eastwards in an imposing headland projecting in the direction of New Britain, and enclosing Huon Gulf on the north side. Between these two chains run the Bismarck and Kritke ranges (10,000 feet), the latter discovered in 1887 by Dr. H. Zeller. About the same time Count Neill, administrator of German New Guinea, penetrated the north coast still farther inland in search of extensive tablelands suitable for settlement; but he found the whole surface broken into a confused mass of steep mountains composed mostly of old sedimentary rocks—altogether a rugged, hopeless region—interspersed by swamps, and with few valleys. All these mountain-ranges converge in the south-eastern peninsula in a single lofty chain which traverses the whole of British New Guinea, but the various sections of which take the names of the Albert Victor, Yule, Owen Stanley, and Lorne ranges, and appear to converge towards the north coast. The nomenclature is still far from settled, and much confusion has been caused by recent travellers renaming peaks and crests and even rivers already determined by previous explorers. The prevailing formations appear to be very old plutonic and sedimentary rocks. Gneiss and granites crop out in the Arfak highlands; elsewhere stratified clayslakes and old limestones abound, containing shells identical with those of south-east Australia; quartz and greenstones occur on the south-east coast resembling those of the auriferous region in New South Wales, and there are numerous other indications of the presence of gold in many districts. Earthquakes are frequent in some places, but no active volcanoes appear to exist, although there are several comparatively recent centers on the spurs of the Owen Stanley range, while pumice and scoria cover the flanks of the Finisterre Mountains.

One result of the explorations has been the discovery of a surprising number of considerable rivers in every part of New Guinea. The three largest appear to be the Amberno (Memberan, or Great River') flowing north from the Empress Augusta in German, and the Fly in British territory. The Amberno (the Rochussen of Dutch geographers) descends from the Charles-Louis range to the east.
side of Geslvinck Bay, where it develops an extensive delta. The Empress Augusta flows from the unexplored central water-parting north-eastwards to the coast of Cape della Torre in 4° S. and 144° 30' E., entering the sea in a broad, deep channel without any delta. In the rainy season it is navigable for many miles by small vessels. The winding stream and several tributaries are accessible for a long way to river-steamers. But the largest of all New Guinea rivers is certainly the Fly, which rises on the southern slope of the central water-parting and flows mainly south-east to a delta of vast extent in the southern part of the Gulf of Papua. The Baxter (Mia Kasa), which enters the sea farther west, opposite Cape York, is an independent stream unconnected with the Fly. This great estuary, which was discovered in 1845 by Blackwood and named after his vessel the Fly, was ascended in 1870 by D'Albertis for 500 miles in a steam-launch, and again in 1889 for over 600 miles by Sir W. Macgregor. The tides ascend the Fly for 150 miles, and 90 miles higher up it is joined on its left bank by the Strickland. Farther east several tributary streams flow from the main range through British territory to the Gulf of Papua have also been either recently discovered or for the first time surveyed. Such are the Douglas, Centenary, Stanhope, and Queen's Jubilee, all of which converge in an almost continuous stream from the head of the Gulf to the sea. But here again the terminology is much confused, the Douglas and Jubilee being respectively Blackwood's Aird and the already partly-surveyed Aivel. Mr Bevan's Phillip also is merely the upper course of the Aird, of which the Centenary appears to be an extension and the Newbery and Blackwood's Aird. The east side of Papua Gulf is joined by other navigable streams from the Owen Stanley range, the more important of which are the St Joseph, flowing from Mount Yule to Hall Sound; the Vanapa, draining the southern slopes to Rescuer Bay, and followed by Sir W. Macgregor on his expedition to Mount Victoria (Owen Stanley) in 1889; the Kemp Weel, flowing to Hood Bay; and the Davadava and HDavada, reaching the coast at Milne Bay. In German territory also, both in New Guinea and in the Owen Stanley range, more than nine new rivers have recently been discovered, one of which, the Markham, gives easy access a long way into the interior.

The whole of New Guinea lies within the track of the south-east trade-winds, which prevail from March to August, and which bring the air charged with much moisture from the Pacific. These are followed for the rest of the year by the north-west monsoons, whose rain-bearing clouds are condensed on the cold alpine slopes of the island. The consequence is that the rain or snow fall is considerable in every part of the country, and this, combined with an average high temperature of from 85° to 90° F., results in a hot, moist climate on all the low-lying coast-lands and fluvial valleys. So excessive is the moisture in some places that 'boots put aside for a day or two grow a crop of mildew nearly half an inch thick.' The climate is therefore favourable for an endemic, not only in the lowlands, but to a considerable height above sea-level, the malignant exhalations being carried upwards by the atmospheric currents, as on the Central African plateaux. At the same time the climate is comparatively free from insect conditions, and its true character still but little understood. It may be very troublesome where weather, soil, and other conditions should be favourable to health, and perhaps almost absent under the opposite conditions ' (Courts Trotter). Exactly similar phenomena in highland parts of Africa indicate it may be inferred that New Guinea, as a whole, is as unsuitable as that continent for European settlement. But some of the uplands beyond the fever zone may be found adapted, if not for permanent colonisation, at least for the establishment of health-resorts for officials, traders, and missionaries. Thanks to its abundant rainfall, varying altitudes, high temperature, and position intermediate between the Asiatic and Australian botanical areas, New Guinea is almost everywhere clothed with a rich and highly diversified flora. The vegetable zones appear to be even superimposed as in Mexico, and Sir W. Macgregor's party, after passing successively the tropical rain-forests, the native forest, the woodland, such as the coconut-nut, sago, banana, mango, taro, and sugar-cane, and of such temperate or subtropical growths as the cedar, oak, fig, nesia, pine, and tree-fern, were gladdened on the higher slopes by the sight of the wild strawberry, forget-me-not, daisy, buttercup, and other familiar British plants. Towards the summits these were succeeded by a true Alpine flora, in which Himalayan, Borrowian (Kimbutu), New Zealand, and subantarctic forms were all numerous. Representing generally the same vegetable chains, a broad range of the tropics and subtropics, the almost continuous forms, from the eastern Alps to the southern continent, Indigenious forms are numerous and include many species of palm. On the other hand, the New Guinea fauna is much more closely related to that of the Austral than to that of the northern hemisphere. This is seen in the numerous genera of reptiles, including the Papuan boa (Chondropython pulcher), intermediate between the Asiatic python and American boa. A still more remarkable intermediate form, supposing a link between reptiles and mammals, is the spiny anteater (Chlamydophorus), introduced through the Melanesian and like it oviparous. There are three species of this ant-eater, while the placental mammals are represented only by some bats and mice, besides the pig and dingo, both probably introduced in comparatively recent times. Man also would seem to have invaded the island after its separation from Australia, for the inhabitants of the two regions belong to fundamentally distinct stocks. Between the Australians and Papuans, who form the great bulk of the New Guinea population, there is little in common except for very remote and distant affinity for the skull of the latter than in the former. But the New Guinea natives are far from a homogeneous people, and the descriptions of travellers in different parts of the island differ so greatly that many anthropologists have doubted or even denied the existence of any Papuan type. There are distinct differences in the presence and intermingling of at least four ethnical elements: Papuan proper, diffused over the whole region; Negrito (Karins and others in the north-west peninsula and probably also in the central highlands); the Malay, and the Melanesians of the south-east coast; lastly, Malay, along the north-western seaboard and around the shores of
Geelvink Bay. The mingling of these elements in different proportions has brought about many strange combinations and a great diversity in the physical appearance, speech, mazes, and general culture of the natives, who, every where broken into small tribal groups speaking a surprising number of distinct languages, some of which are members of the widespread Malayo-Polynesian family, while others, especially in the interior, seem to have no connection with that or any other known forms of speech. The tribal organisation is extremely loose, hereditary rulers being nowhere recognised, and the so-called chiefs demanding for their prestige either on personal, sectional, or group, or even on economic grounds.

New Guinea appears to have been first sighted by A. D’Abanc in 1511, and first visited by De Moresbi in 1623, and Alvaro de Saavedra in 1728. It received its present name in 1546 from Ortiz de Retez (Rodol), who was struck by the resemblance of its inhabitants to those of the Guinea coast in West Africa. During the flourishing period of the empire of Tidor, the Malay sultans of that state extended their sway over the so-called Raja Ampat or ‘Four Kingships’ of Waijin, Salawa, Mysol, and Waigamun, including large tracts on the adjacent mainland. In 1799 the East India Company occupied the island of Manaseeri in Geelvink Bay; but the British troops were soon withdrawn, and in 1814 the English government admitted the islanders of Hollandia to the Raja Ampat as suzerain of the sultan of Tidor. In 1848 the Dutch proclaimed their sovereignty over the western half of the island as far as 14° E. long., and this meridian was accordingly taken as the western boundary of the eastern half in 1884, when that section was divided between Great Britain and Germany. The boundary between the northern or German and the southern or British division coincides with the crest of the main water-parting. Subjoined is a roughly estimated map of the areas and populations of the territories assigned to these three states:

<table>
<thead>
<tr>
<th>Area in sq. miles</th>

</table>

In the Dutch section, which is attached to the Residency of Ternate, there are no towns or administrative centres, Dorye, at the north-west side of Geelvink Bay, being merely a missionary station. The starting-point of many expeditions to the interior. Government has ever been made by the Dutch government or by private enterprise to develop the resources of the country.

German New Guinea, officially known as Kaiser Wilhelm Land, is a protectorate administered by the German New Guinea Company, which stations at Astrolabe Bay, Finschhafen, Konradshafen, and Hatzfeldhafen. It yields for export tobacco, areca, sago, bamboo, ebony, and other woods. British New Guinea, which includes the D’Entrecasteaux and Louisiade Archipelagos, was administered as a protectorate under a Commission till 1888, when the sovereignty of the Queen was proclaimed, the government being placed under Sir William Macgregor as Administrator. New South Wales, Victoria, and Queensland each contribute £3600 towards the expenses of administration. The territory is divided into western, central, and eastern division, under deputy-commissioners, residing at Port Moresby. The revenue already exceeds the expenditure, and the exports, chiefly gold, pearl-shells, bêche-de-mer, and copra, exceeded £24,000 in 1889.
schools are efficient, and the state possesses one college—Dartmouth, founded at Hanover in 1769 as a school for the instruction of Indians; it has well-appointed academic, scientific, medical, and agricultural departments, with libraries aggregating 87,000 volumes. There is also a state normal school at Plymouth.

History.—The earliest settlements were made in 1623 near Dover and Portsmouth. In 1641-79, 1659-92, and 1659-74 New Hampshire was joined to the Massachusetts colony, but during the intervening dates it formed part of New England, and was in its own right a county of 570 sq. m. Its physical characteristics resemble those of New Britain (q.v.).

New Harmony, a town (pop. 1341) of Indiana, 30 miles by rail WNW. of Evansville, was first settled in 1815 by a German community of religious socialists, called Harmonists, under the leadership of George Rapp (q.v.). In 1824 the village and domain was purchased by Robert Owen, for an experimental community on his system; but this failed after a test of nearly three years.

New Haven, a seaport of Sussex, at the mouth of the Ouse, 3½ miles E. of Brighton and 50 S. of London, and is prosperous. It has an important seaport, and is the chief port of the Is. of Wight. It has also a well-developed steamboat traffic, particularly to Dieppe (5 hours), and has a large fort (1864-90) and a little Norman 12th-century church, with an east tower and small semicircular apse, curiously like that of Yainville-sur-Seine. (Pop. (1881) 4421; (1891) 4965.

New Haven, a fishing-village of Midlothian, on the north shore of the Firth of Forth, 1 mile WNW. of Leith, and 2 miles N. of Edinburgh. Dating from about 1490, it has a tidal harbour, reconstructed in 1876-77 at a cost of £10,000, and is famous for its fish dinners and fishwives. Pop. of the village (1801) 126; of Charles Read's Christie Johnstone (1853), and Mrs Cupples Newhaven, its Origin and History (1888).

New Haven, the chief city and seaport of Connecticut, and capital of New Haven county, at the head of New Haven Bay, 4 miles from Long Island Sound, and 75 miles by rail ENE. of New York. Its broad streets are shaded with elms, and the public squares, parks, and gardens, with its handsome public and private edifices, make it one of the most beautiful of American cities. It is the seat of Yale College (q.v.), and contains also the State Lunatic Hospital, and Agricultural school (1690), and thirty-four public schools. Its other public buildings include the former statehouse, the city hall, United States government building, and about sixty churches. The harbour has a jetty and a breakwater surrounded by a light-house and lighthouse. New Haven has a busy trade. New Haven is of more consequence as a manufacturing town, employing many thousands of hands in its large works, and producing hardware, wire, locks, clocks, cutlery, firearms, corsets, patent rubber goods, carriages, furniture, paper, matches, &c. New Haven was settled in 1638 by a company from London, and the colony was not united to that of Connecticut until 1662; and till 1783 it was recognised as, jointly with Hartford, the capital of the state. It was incorporated as a town about 1663, and chartered as a city in 1784; and it retains a town as well as a city administration, choosing selectmen, &c., besides a mayor, aldermen, and council. (Pop. (1850) 13,291; (1860) 15,800; (1870) 19,450; (1880) 25,581; (1890) 31,454.

New Hebrides, a chain of islands in the Western Pacific, extending NWW. to SNE, and lying W. of Fiji and NE. of New Caledonia. There are in all some thirty islands (area, 5110 sq. m.), of which twenty are inhabited, the people, mostly of the Melanesian race, numbering about 70,000. The islands are very mountainous, and are bordered by a coral reef, and surrounded by a narrow lagoon. The larger islands are Espiritu Santo (70 miles long by 40 wide), Malicolo (50 miles by 20), Ambrym (22 miles by 17), Vaté or Sandwich (30 miles by 15), Erromango (20 miles by 15), Tanna (18 miles by 10), and Aneityum (35 miles in circumference). All are wooded, and some lofty, reaching 3000 feet. The climate is moist, but clear and healthy, the thermometer ranging from 60° to 90° F. The usual tropical plants and products are grown—yam, taro, bananas, breadfruit, nutmeg, pineapple, and cocoa-nut. Sandalwood, at one time common, is now almost extinct. The seas swarm with fish, some of them poisonous, and whales are taken near by. The people are savage cannibals of a low type, and are decreasing in number. They speak a great number of dialects, many being unintelligible to the others. The southern islanders (Erromanga to Aneityum) have been civilised by English and Scottish missionaries. This chain was discovered by the Portuguese navigator Quiros in 1606, and was thoroughly explored by Captain Cook in 1778. They are claimed by the British, though nothing is done to occupy them. The French have more than once east covetous eyes upon the group, but their attempts to annex it have encountered the strenuous opposition of the Australian colonists. Since 1867, 26 natives of these islands have been every year carried away to serve as labourers on the plantations in Queensland, Fiji, and New Caledonia, and many harbrarities have been perpetrated in connection with the traffic. See Dr J. Inglis, In the New Hebrides (1887) and the Memoir of J. G. Paton, F.R.G.S., 1888.

New Holland. See Australia.

New Ireland, now called New-Mecklenburg, a long narrow island in the Pacific Ocean, lying to the north-east of New Guinea. Area, 4900 sq. m.; length, 300 miles; width, 15 miles. The hills rise to 6500 feet, and they and the whole of the interior are richly wooded. The climate, products, and inhabitants resemble those of New Britain (q.v.).

New Jersey, the name of one of the original states of the American Union, bounded on the N. by New York; E. by the Hudson River, Staten Island Sound, Raritan Bay, and the Atlantic Ocean; S.W. by Delaware Bay; and W. by the Delaware River, which separates it from Pennsylvania. Its greatest length is 107 miles; its width varies from 32 to 59 miles. It has an area of 7815 sq. m.; it is the smallest of all the states save three, but it ranks sixteenth in population, and the third in population per square mile.

In the north-west part of the state there are two portions of the Appalachian system. The Blue or Kittatiny Mountains extend along the Delaware from the Water Gap (1817 ft.) to the Delaware Water Gap (1800 ft.). The Blue mountains south and east of these consist of many ridges, their greatest height 1488 feet. In this part of the state are small lakes. The Palisades, the Orange Mountains,
and other hills are in the red sandstone region, which extends from the north-east to the central part of the state, and includes the highlands south of Sandy Hook, reach a height of 292 feet, support two lighthouses, and are the only considerable elevation on the Atlantic coast south of New England. The central portion of the state is generally level and fertile; the southern part is in large measure sandy, covered with pines, and sandy near the coast. The state is abundantly watered; its chief rivers, the Passaic, Raritan, Little and Great Egg Harbor, flow southeast into bays. The coast from Sandy Hook to Cape May is generally protected by peninsula or island beaches; the only considerable exception to this rule being the strip of mainland, about 18 miles long, between Monmouth and Squan beaches.

In agriculture the state occupies a prominent position in proportion to its area. The farms comprise some 3,000,000 acres, more than three-fourths under tillage; the value of the crops approaches $200,000,000, and that of farm products is about $300,000,000 annually. The chief products are maize, oats, wheat, rye, hay, potatoes and sweet potatoes, cattle, butter, and milk. The leading mineral products are iron ore, limestone of various kinds, granite, marble, clay, china, leather, silk, and sugar are among the chief manufactures.

New Jersey returns ten members to congress. The state legislature meets at the capital, Trenton, in February. Each senator is chosen from each of the twenty-one counties (one-third each year) for three years; the assembly has about sixty members, who serve one year. The annual taxes are about $3,000,000, of which full half is devoted to education. There are (besides seven county asylums) twelve asylums near Trenton and Morristown, the latter accounted a model; an institution for the deaf and dumb, an industrial school for girls, and a large state-prison, at or near Trenton, a reformatory school for boys near Jamesburg, and a home for disabled soldiers at Newark. There are about 1,400 schools that educate in the cities over 100,000 pupils and some 240,000 in the rural districts. The state normal school is at Trenton, and its preparatory school at Beverly; and the state agricultural and scientific school is connected with Rutgers's College, at New Brunswick. At Princeton (q.v.) is Princeton University, founded in 1746 as The College of New Jersey, the most famous institution in the state.

New Jersey has two canals, the Morris and the Raritan, and some fifty railroads, with nearly 3000 miles of length. The position of the state, between the two great eastern cities and bordering upon both, has powerfully stimulated travel, industry, and population. Its south-west portion has Philadelphia for a market; its north-east section, including its two largest towns, is a suburb of New York. Its coast from Navesink to Squan is covered with villages, and have Cape May and Long Branch for half a century, and Atlantic City for twenty years or more, have been noted seaside resorts. Ashbury Park, Ocean Grove, Seabright, &c., are now growing places, created for the enjoyment of New Englanders. Camden, Trenton, Hoboken, Elizabeth, Bayonne, Atlantic City, and Passaic. Pop. (1890) 211,149; (1855) 49,535; (1890) 1,244,933; (1800) 1,833,699.

It was in 1655, the Dutch settled at Bergen, near New York. In 1629 Cornelius May ascended the Delaware and built a fort four miles below the site of Camden. Some English colonists in that region were driven away in 1658 by the Swedes, who were conquered in 1663 by Peter Stuyvesant. In 1664 the territory was granted by Charles II. to the Duke of York, and by him to Lord John Berkeley and Sir George Carteret, with full powers of government and their assigns. There was no trouble with the Indians, whose titles were peacefully purchased. The proprietors soon divided the territory into East and West Jersey. In 1674 Berkeley sold West Jersey to two Quakers, who settled Salem and Burlington, and in 1682 a society was interested in the Carteret rights in East Jersey. In 1702 the proprietors surrendered their power of government to the crown, and the two provinces were reunited; and from 1738 New Jersey had its own royal governors, always at issue with the assembly and the people. New Jersey bore its part in the colonial warfare, contributed 10,726 men to the Continental army, besides militia, and spent over $5,000,000 in the cause of liberty. It suffered heavily during the revolution, and was the scene of several important campaigns and battles. The state sent nearly 7000 men to the war of 1812, and for the civil war thirty-seven regiments of infantry, three of cavalry, and five batteries. See the History of New Jersey, by Rain (1880).

New Jersey Tea, a common name of Red Root (q.v.).

New Lanark. See LANARK.

New London, a city and port of entry, the semi-capital of New London county, Connecticut, is on the right bank of the river Thames, 3 miles from Long Island Sound, 51 by rail. E. of New Haven, and 190 NNE. of New York, with which it has railway and steamboat communication. It has a courthouse, a brown-stone city hall, a granite custom-house, a new government public building, hospital, public library, and four parks. The manufactures include woollens, sewing-silk, agricultural machinery, bicycles, printing-presses, hardware, and crackers. The harbour (50 feet deep) is one of the best in the United States. On the left bank of the river is a United States navy yard; and there are two forts here, one no longer effective. New London was settled in 1645, and in 1781 was burned by Benedict Arnold. Pop. (1890) 13,757; (1899) 17,584.

Newman, John Henry, Cardinal (1801-90), the leading of the Oxford Tractarian movement of 1833 in the Church of England, and the founder of the Roman Catholic Church in 1845, and was made a cardinal by Leo XIII. in 1879. He was born in London on the 21st February 1801. His father was John Newman, a member of the banking firm of Ramsbottom, Newman, & Co. His mother was the child of an old Huguenot family which had settled in London as paper-manufacturers. She was a moderate Calvinist, and taught her children to love the school of Scott, Romaine, Newman, and Milner. Her children learned early to take great delight in the Bible, and Newman was always a modest and humble man. In the early years of his life he traced in his mind the way in which his early religious views to his mother's teaching. From Scott, the commentator on the Bible, he learned principles which may be traced in all his subsequent career. The first was to prize "reasonableness above all else," the second was "the growth of the soul, not only through the exercise of life." From his reading of Law's Serious Call he dutes his firm inward assent to the doctrine of eternal punishment, which he always held as taught by our Lord himself; a doctrine, however, of which he was often embarrassed in the writings of the early Fathers. Yet at the same time he derived from Newton's book on the prophecies a belief which more or less biased his mind long
after he had ceased to accept it as a truth—that Rome is Antichrist. In the autumn of 1816 a belief took possession of him, as he tells us in his Apologia, that he was to lead a life of celibacy; and this belief held its ground for about a month, and a month then, up to the age of twenty-eight, after which it remained absolutely fixed. Newman went to a private school at Ealing. The stoppage of his father’s bank compelled him to take his degree at Oxford as early as possible. He returned to London for a vacation, and he actually took it (from Trinity College) in 1820, when he was only nineteen, but overwork resulted in a partial failure. In 1821 he wrote jointly with a friend two cantos of a poem on St Bartholomew’s Eve, but the fragment has never been republished. It should be added that Newman was always passionately fond of music, and showed delicacy and skill as a violinist.

In 1822 Newman was elected to a fellowship in Oriel College, then the most distinguished in the university; and it was here that, after a period of some loneliness, he formed his chief friend Dr Pusey, and subsequently with Hurrell Frondes, whose dash and genius exerted a great influence over Newman, and who had a great share in starting the Tractarian movement of 1833. In 1823, too, Newman first read Butler’s "Analogy," from which his faith probably derived the less certain aspects of natural religion in the sense of revealed religion, and especially to interpret natural phenomena in the sense of the sacramental system—i.e., as conveying mystical spiritual influences of which there is no external sign. Kelke’s "Christan Fear" (1827) fell in exactly with this impression of the mystery at the heart of apparently purely physical influences. From Bishop Butler Newman also derived the principle that ‘probability is the guide of life,’ which, however, he made less material when he became Roman Catholic, holding thenceforward that in all matters of first-rate religious importance certitude can be attained and not merely probability. At Oriel Newman formed cordial relations with Dr Hawkins, afterwards the provost of the college, and Newmanly, afterwards Archdeacon of Dunblane, both of them exercised great influence over him by teaching him to define his thoughts clearly; and he afterwards expressed surprise that the casuistry of the Roman Church should have been credited with those habits of subtle discrimination which he had acquired in the Presbytery.

Newman’s first book, completed in 1832, but not published till 1833, was that on The Arioms of the Fourth Century. It was a very careful and scholarly production, intended to show that the Ariom heresy was not, as had been supposed, of Alexandrian origin, but was one of the Judaeistic heresies which sprang up in Antioch. The book is a powerful vindication of the Athanasian doctrine of the divine nature of Jesus Christ from the imputation of being arbitrary, or in any way an unaccountable, and therefore public scandal to the Pauline and Johannine theology. Newman insists on the dogmatic definition of the Son as being ‘of one substance’ with the Father, and not merely ‘of like substance,’ as the only escape from either creature-worship on the one hand or the impossible ascension of the voluntary self-sacrifice of an eternal creator on man’s account on the other.

In the late autumn of 1832 Newman accompanied Hurrell Frondes and his father in a Mediterranean voyage undertaken in the hope of restoring the health of the latter. A month or two later, Newman thought that the fire gradually kindled which was to bear fruit in the Anglican movement of 1833. Most of Newman’s smaller poems were written on this voyage, and were soon afterwards published with the signature δ in the Lyra Apostolica, a volume of verse the object of which was to reassert for the Church of England her spiritual authority and mission with the Papal dignity and literary grace and buoyancy of poetical license. It was on this tour that Newman first saw Monsignore (afterwards Cardinal) Wiseman in Rome, and told him gravely in reply to the expression of a courteous wish that Hurrell Frondes and he might revisit Rome, ‘We have a work to do in England,’ At this time Newman left his friends to go alone to Sicily, where he fell ill of malarial fever. His mind was deeply possessed during this illness by the idea of the work he had to do in England, and the delay in finding passage to England was very trying to him. He spent much of his time in the Roman Catholic churches, which he had up to this period refrained from visiting, and speaks with great feeling in one of his poems of the good offices of that church, though a ‘foe,’ in ministering to his sickness, like the good Samaritan to the wounded man. At last he got passage on an orange boat to Marseilles. Beforning the Straits of Bonafaeo, he wrote the best known of all his poems, ‘Lead, kindly Light.’ From Marseilles he travelled straight to England, reaching home in time to be present at Keble’s Oxford prize sermon, and to see the movement of the Tractarians always regarded as the date at which the Tractarian movement began. It was preached on July 14, 1833.

Into the series of Tracts for the Times which now commenced Newman threw himself with great energy; indeed he himself composed a considerable number of them. In the very first page of the first tract, which was his own, he told the bishops that ‘black event though it would be for the country, yet we could not wish them a more blessed termination of a trial carried on by the spoiling of their goods and martyrdom.’ The tracts which now began to pour forth were all intended to assert the authority of the Anglican Church, to claim apostolical descent for the Anglican episcopate, to advocate the restoration of a stricter discipline and the establishment of Insular bishops, to insist on the primary importance of the sacraments, and the duty of loyalty to the church—Newman persuaded a friend to stay away from the marriage of a sister who had seceded from the Anglican Church—and in general to preserve the dogmas of the Church. In this he was unreservedly guard her divine ritual. But while he was full of confidence in these principles, which he held in common with Rome, what puzzled him was to justify adequately the strong anti-Romanist language of the greater Anglican divines; and a great part of his time was given during the Tractarian movement to laying down clearly the doctrine of the via media or midway course between popular Protestantism and Roman Catholicism, which he claimed that the Anglican divines of the 17th century had sufficiently enunciated. After he had passed through his Anglican period he disapproved strongly the cultus of the Virgin Mary and the saints as interfering with the true worship of God. In 1837 he made an attempt to distinguish the Anglican via media from the doctrine of the Church of Rome in a course of lectures on ‘The Prothetical Office of the Church viewed relatively to Romanism and Popular Protestantism.’ In these lectures he contrasted the attitude of the Anglican and Roman churches in reference to the use and abuse of private judgment, their attitude towards the principle of private judgment, the text of Scripture, and their view of the fortunes of the church. But while defending and defining as far as possible the via media of Anglicanism,
Newman frankly admitted that it had never been practically enforced, and that it was a theoretical doctrine of justification by faith which he had never before held. This it was which remained for the Tractarians to do.

In 1838 Newman followed up his discussion of the *via media* so far as it affects authority with a volume on the *via media* in its relation to the doctrine of justification by faith. On the one hand he taught that the Anglican Church takes a middle course between the Roman Catholic Church and popular Protestantism in maintaining that justification by faith—or the *imputation* without the reality of righteousness—most precise sanctification, which will bring about a brotherhood among christians necessarily follow; while the Roman Catholic theology regarded sanctification as the whole substance of justification.

In Tract 53, which was also published in 1838, Newman made an effort to apply the theology of the *via media* to the interpretation of Scripture. He held that the Roman Catholic Church takes a view too independent of Scripture, while the Anglican Church is right in asserting that all revealed doctrine is to be found in Scripture, though it could not be found there. A volume of some extent is needed to guide the church's traditions to help us to find it there. He admitted most fully that the stress which one might expect to be laid is not laid in Scripture on baptism, on confession, on absolution, nor even on public worship itself, and that we can only find these doctrines in Scripture by attaching the importance which tradition teaches us to attach to the hints and obiter dicta of Scripture. Scripture, he held, verifies the teaching of the church rather than systematically inculcates it. Tract 53 was one of the most careful and characteristic of all Newman's essays as a Tractarian.

Tract 90, which appeared early in 1841, and which gave rise to so much agitation in Oxford, was the most famous, but certainly one of the least interesting of the tracts. The rigid wing of the Tractarian party, headed by William George Ward, was at this time urging Dr Newman to reconcile his High Church doctrines with the Thirty-nine Articles. This Newman thought a comparatively easy matter. The Articles recognize the teaching of the Books of Homilies as 'goddly and wholesome'; and Newman contended that there was therefore ample evidence that the intention of the Articles was Catholic in spirit, and that they were aimed at the supremacy of the pope and the popular abuses of the Catholic Church in practice, and not at Catholic doctrine. The Homilies regard the first seven hundred years of the Catholic Church as quite pure, recognize six councils as received by all Christians, and speak of many of the Fathers as inspired by the Holy Ghost. Clearly therefore, in Newman's opinion, they were meant to gain over the moderate Romanists; and so they did not provoke a council in a way that the Council of Trent, for when the Articles were promulgated the council was not over. But in spite of this really substantial defence for the Anglican view of the Articles, Tract 90 provoked an explosion which was the end of the Tractarian movement, and which had far from the apparent finish of the Tractarians who were most logical as well as most in earnest. The tract was repudiated by those in authority; the bishops almost all declared against the movement; Newman struggled for two years longer to think his position tenable, but in 1843 received a mandate of St Mary's, which he held since 1828, and retired to Littlemore (q.v.). The magnificent university sermon on 'Development in Christian Doctrine,' which was the preliminary stage of his *Essay on Development,* was the last which he preached in the university pulpits, on the 24 February 1843. During his life at Littlemore he became a prey to a new and grave disloyalty to his church—for example, of being a Roman Catholic already, who only concealed his change of faith in order to exert more influence over other Anglicans—a course of which he was quite incapable. On the 4th October 1845 he invited the Pessimist Father D huntington, from Littlemore in order that he might be received into the Roman Catholic Church, and on the following day he was received; and within a few months he had left Oxford, which he never saw again for thirty years.

Of Newman's life as a Roman Catholic it is necessary to speak only briefly. It was, however, in a literary point of view much more free and natural than his somewhat repressed and severely reined-in life as an Anglican. He first went to Oscott to be confirmed; then he went to Rome for two years and a half; and on his return in 1848 he published *Loss and Gain,* the story of an Oxford conversion very different from his own, but full of happy and delicate sketches of Oxford life and manners. Shortly afterwards he began, but did not at that time publish the account of his life as a martyr in Africa of the 3rd century. The little book is full of literary genius as well as of religious devotion, and it contains a most vivid picture of the devastation worked by the hecatombs in that country, as well as a still more impressive picture of Newman's conception of the phenomenon of demoniacal possession. In 1849 Newman established a branch of the brotherhood of St Philip Neri (q.v.) in England (see ORATORY). Newman established himself at Edgbaston, a suburb of Birmingham; and here he did a great deal of hard work, devoting himself to the sufferers from cholera in 1849 with the utmost zeal. The lectures on Anglican Difficulties, intended to show that Tractarian principles could only issue in submission to Rome on the part of any Tractarian who had a logical perception of what the movement meant, was the first book which drew public attention to Newman's great power of irony and the singular delicacy of his literary style. These lectures were delivered and published in 1850, and were followed in 1851 by the Lectures on 'Catholicism in England,' in which the Protestant prejudices of the time concerning Roman Catholicism were painted with a great power of ridicule and even caricature. This was the book which gave occasion to Dr Acland's action for libel against Newman, tried by Lord Campbell, in which the verdict went against Dr Newman so far as this, that the jury thought that he had not succeeded in justifying the libel, and awarded damages of £100 against him, while the costs of the case are said to have amounted to £10,000. Lord Campbell's charge was deemed very one-sided even by Protestants.

Newman will probably be longer remembered as a great preceptor against the Protestant prejudice than as a preacher. A series of Oxford sermons contain some of the finest ever preached from an Anglican pulpit, and his Roman Catholic volumes—*Sermons addressed to Mixed Congregations* (1849) and *Sermons on Various Occasions* (1857)—though less remarkable for their subjects, are yet proofs of that fine genius which shone from the fairest finish. In 1864 a casual remark by Canon Kingsley in *Macmillan's Magazine* on the indifference of the Roman Church to the virtue of truthfulness, an indifference which he asserted that Dr Newman approved, led to a correspondence which resulted in the publication of *Analecta pro Vitae Sua,* which he afterwards recast as *A History of My Religious Opinions.* In this book Dr Newman gave us much the most fresh and effective religious autobiography of the 19th century.
and completely vindicated the simplicity and candor of his own theological career. It is perhaps the most fascinating of his many works, as it led to the revision of Wordsworth's "The Dream of Gerontius." It is a poem of marvellous subtlety and pathos, as unique in treatment as it is in subject, and is now republished in Newman's "Various Occasions" (1874), which contains also all the pieces originally published in the Lyra Apostolica. In 1870 he published his Grammar of Assent, a book on the philosophy of faith, based on the view that a believing and even credulous attitude of mind clears itself much more easily of false beliefs than a sceptical attitude of mind clears itself of false denials. In the controversies which led to the Vatican Council Newman sided with the Inopportunists. He believed that the decree of the pope's personal infallibility in putting forth ex cathedra definitions on theology or morals intended to teach the church would alienate many Anglicans from the Roman Church, and he thought the doctrine, though true, not ripe for definition, nor pressed upon the attention of the church by any heresy. He was at the same time a member of the Utrecht Montanists under Archbishop Manning and William George Ward, and the bitterness between the two parties ran very high. Nothing seemed less likely at that time than that Newman should ever become a Cardinal; but after the death of Pio Nono and the election of Leo XIII, the policy of the Vatican church altered, and the new pope was very anxious to show his sympathy with the moderates in various countries, and especially with the English Catholic moderates, of whom Dr. Newman was much the most distinguished. Accordingly in 1879 Newman was summoned to Rome to receive the Cardinal's hat, which was conferred on him in a secret consistory on the 12th May in that year. In acknowledging the congratulations which flowed in upon him on that event he renewed his protest against liberalism in the way he conceived that a wise man should, in the interest of the Church and the country, speak the truth. In the sense of the difficulty of treating Scripture as plenarily inspired, its tendency being to suggest that inspiration does not necessarily include mere matters of detail in history, unless these are of the nature of what are called 'dogmatic facts'—i.e. facts which lie at the basis of revealed truths, such as the supernatural birth of Christ. Cardinal Newman died on the 11th August 1890, after a very short illness, of pneumonia.

See a work on Newman by the author of this article (1890); and Cardinal Newman's Letters and Correspondence, edited by Miss Mozley (1891).

**Newman, Francis William,** brother of the preceding, was born in London in 1805, and educated at a private school at Ealing. Thence he passed to Worcester College, Oxford, where he obtained his B.A. in 1826, and, in the same year, a fellowship in Balliol College. This fellowship, however, he resigned; and he withdrew from the university in 1830, at the approach of the time for taking the degree of M.A., declining the subscription to the Thirty-nine Articles, which was required from candidates for the degree. After a three years' stay in the East, he was appointed classical tutor in Bristol College, 1834. In 1840 he accepted a similar professorship in Manchester New College, and in 1846 his reputation led to his being appointed to the chair of Latin in University College, London, which he held till 1863; meanwhile he was an active contributor to numerous literary and scientific periodicals in England, and took an active part in modern literature. In controversies on religion he took a part directly opposite to that chosen by his elder brother, being no less eager for a religion in his view more world-wide, and including whatever is best in the historical religions. "Phases of Faith" is by far the most widely diffused of his works, simply because it was mainly negative; but it was preceded by a book called The Soul (1849), which aimed to show a solid ground for divine aspirations in the human heart. His smaller moral and religious essays are now collected in a single volume (2 vols. 1871), a Handbook of Modern Arabic (1866), giving the dialect now used by literary men in all Arab-speaking regions; and a Libyan Vocabulary (1882), in which, cutting out the Arabic, he tried to reproduce the old Numidian, Mauretanian, and Gattarian. He also published in connexion with Philip Brown a "Syllabus of the Roman Constitution" (1888-90); and a small book on the earlier life of his brother, Cardinal Newman (1891). Died in 1897.

**Newmarket,** the 'racing capital of England,' lies on the border of Suffolk and Cambridgeshire, 14 miles ENE. of Cambridge and 69 NNE. of London. Twice almost destroyed by fire, in 1683 and 1700, it chiefly consists of one long street, and contains a usual number of houses and large shops, belonging to the great patrons of the turf. Principal equestries are the Jockey Club (1773); the adjoining Subscription Rooms (1844); the Proprietary Club (1882); the Jockey Memorial Hospital (1883), with almshouses for eight jockeys and trainers or their widows; St. Mary's Church, Perpendicular in style; and All Saints (1777). The town owes its prosperity to its horseraces, as old at least as 1605; and nearly half the male population are jockeys, trainers, or stablemen (Holford the dramatist was once one of their number). The race-ground, a large market-square, which is traversed by the Devil's Dyke (see Cambridgeshire), is owned partly by the Jockey Club, partly by the Duke of Rutland, and, with its soft elastic turf, is one of the very finest in the world. Of its ten courses, the longest is 4½ miles in circuit. The training ground bears a like character for excellence; and 400 horses are constantly in training. There are seven annual meetings, the principal events being the Two Thousand at Easter and the Cesarewitch in October. Pop. (1881) 3556; (1891) 5093; (1901) 6213. See HORSE-RACING; and J. P. Hore's History of Newmarket and Annals of the Turf (3 vols. 1886).

**New Mexico,** a thinly-peopled territory in the SW. part of the United States, is bounded N. by Colorado, E. by Oklahoma and Texas, S. by Texas and Mexico, and W. by Arizona. Area 122,590 sq. in. It is the most western part of Great Britain and Ireland. Pop. (1880) 119,565; (1890) 153,593; (1900) 190,510. New Mexico is thus the fifth in area and the forty-fifth in population of the states and territories of the continental United States. The surface of New Mexico is the great plateau upon which rests the Rocky Mountain system. From an altitude of 6000 to 6500 feet in the north it descends gradually to about 4000 feet along the Mexican border, and sinks to 3000 or 3500 in the llano Estacado of the south-west. Except in the east the whole region is traversed
by broken ranges of mountains having in general a north and south trend. In the northern central part the Santa Fé, Las Vegas, and Taos ranges form the eastern boundary of the Rocky Mountain region, with a number of peaks over 12,000 feet high. Farther south, and east of the Rio Grande, are numerous broken ranges; and west of the Rio Grande the Sierra Madre rise above the level of the sea (plateaus) in various ranges. These mountains and the intervening valleys are cut by deep canyons. In the north-west a number of chains cross the Arizona boundary, and the San Juan Mountains enter the territory from Colorado. Among the mountains, especially in the north-east, are many 'parks' noted for their beauty and fertile soils. The surface rocks belong mainly to the Cretaceous period, with belts of Triassic formation. The mountain-chains and great part of the Sierra Madre plateau are much older. There are many tracts of metamorphic rock and lava outflows, some of which appear to be of comparatively recent date.

The precious metals are found in almost all parts of the territory. Some of the most important mines are in the south-west near Silver City, Deming, and Lordsburg, others in the central region in the vicinity of Socorro, and farther north near Santa Fé. There are also valuable mines in New Mexico. Some of the minerals are gradually worked by the early Spaniards, who compelled the Pueblos to labour like slaves. In several places old shafts have been discovered which were filled by the Indians when they successfully revolted from this tyranny. Copper and iron occur in valuable deposits, and near Santa Fé are the famous turquoise mines. There are also fields of both bituminous and anthracite coal. Mineral and hot springs are numerous.

The great mountain-divide causes the drainage of New Mexico to flow south to the Gulf of Mexico, and west to the Pacific Ocean. The Rio Grande traverses the central part of the territory and receives many tributaries. The Rio Pecos which joins it in Texas drains the south-eastern part. In the north-east are streams which unite to form the Canadian River, and in the west are the head-waters of the San Juan, Litish, and all the affluents of the Colorado. In the river-valleys the soil is fertile and produces excellent crops; and many acres in other sections may be successfully cultivated by irrigation. The climate is healthful, and on the whole remarkably uniform, and the abundance of water and extensive pastures free from pulmonary diseases is the lowest in the country. The rainy season occurs between the middle of July and the middle of September, lasting about a month. There are extensive forests on the mountains, and in the hilly regions of the western part of the territory, and on the pastoral plains nutritious grasses which support great numbers of cattle and sheep. The yucca and caustus are characteristic forms of vegetation, especially in the Llano Estacado. Stock-raising is one of the leading industries. The sheep and goats need no housing in the winter, but of late years more attention has been given to improvement of the breeds, and the stock, instead of roaming at will, is often confined within enclosed ranges.

Though one of the most recently settled portions of the United States, the eastern part of the earlier region occupied by the white man, and Santa Fé, originally an Indian pueblo, claims the title of the oldest town in the country. When the Spaniards first visited this region they found a people living in communities with substantial dwellings, and marking their valley with colonies and monuments in previous centuries. In 1822 the people of New Mexico, in common with the other inhabitants of Mexico, of which it then formed a part, threw off the Spanish yoke. By the treaty of Guadalupe Hidalgo in 1848, after the war between Mexico and the United States, part of the territory was acquired, and thirty-live miles of railroad were made by a later purchase from Mexico and by a cession from Texas. The population still includes about 100,000 Mexicans, as well as nearly 40,000 Indians. The territory when originally organised in 1836 included Arizona and parts of Colorado and California. The construction of railroads, begun in 1878, had a marked influence in its development. There are now about 1400 miles of railroad, connecting with each other and with all parts of the Union.

There are nineteen counties in New Mexico, and the principal cities and towns are Santa Fé (the capital), Albuquerque, Las Vegas, Taos, and Socorro. The common-school system was established by an act of legislature in 1891; the board of education consists of five members, including the governor of the territory. Numerous institutions are conducted under Roman Catholic auspices. There is a state university at Albuquerque, an agricultural college at Las Vegas, and a school of mines at Socorro. Schools for the Indians are largely attended.

Newnham College, just outside Cambridge, but within ten minutes' walk of the centre of the town, may be said to have commenced in 1871, when the Newnham Hall Company opened a house for resident women students, and the numbers steadily increased, and in 1875 Newnham Hall was built, providing rooms for the principal, a lecturer, and twenty-six students. Scholarships were given by the London Companies and private friends, the library grew, a chemical laboratory and gymnasium were added, and the machinery of the college became more and more complete till, in 1879, the Newnham Hall Company was amalgamated with the Association for the Promotion of the Higher Education of Women. Additional land was acquired, a second, and finally a third hall was added. These three halls, Old Hall, Sidgwick Hall, and Clough Hall, now form Newnham College, where at the present time 147 students, under the charge of a principal, two vice-principals, and five lecturers, receive instruction, partly by lectures delivered at Newnham, partly by lectures and exercises conducted by the college of the university as are open to them. In the year 1881 the university of Cambridge opened to students of Newnham and Girton its tramps and previous exams, and in 1889, out of thirty-five students of Newnham who entered for the tramps exam, six took a first-class, sixteen a second-class, and nine a third-class; while in 1890 Miss Fawcett was placed above the senior wrangler. Careful superintendence is here combined with a large amount of liberty and responsibility. The greater number of students work for tramps and stay for a course of three or four years, but special courses of work can be taken without examination. The fees are 75 guineas a year.

New Orleans, the commercial metropolis of Louisiana, and the most important city of the southern United States, is situated on both sides of the Mississippi River—the greater portion on the east and south bank. Its corporate area is 187 sq. m., but a large portion of this is market-gardens, forest, and swamp, and only 48 sq. m. are built over, fronting on the Mississippi, and running back from half a mile to 3 miles. The city proper has a population of 115,000, and the largest district, 'Algiers,' of 3 miles. The Mississippi makes two bends here, giving the old city a crescent-shaped front, whence its former title, 'The Crescent City,' but it is
new the shape of the letter S. The river is from 600 to 1000 yards wide, and 60 to 240 feet deep. The bar at its mouth was removed in 1874-79 by the Eads jetties in South Pass, and vessels of 30 feet now easily reach New Orleans. The commerce of New Orleans is about $350,430,315 in 1890.)

The large engagement was in 1891, in Spain (q.v.); but the police and militia, in which 46 persons were killed and 216 wounded; and the lynching in 1891 of 11 Italian mafiosi. In 1880 the capital of Louisiana was removed from New Orleans to Baton Rouge.

Pop. (1769, when it was transferred to Spain) 5165 (1802, when it became the American) 10,308; (1840) 102,193; (1860) 216,190; (1890) 242,039, only 19 per cent. of whom were of American or English descent, 17 Creole or French, 14 German, 12 Irish, 8 Italian, 5 Spanish, Scandinavian, Jewish, &c., 16 negroes, and 9 of mixed races, Indians, Chinese, and Mafa, a population as cosmopolitan in race and language (1900) 287,104.

New Plymouth, the chief town of the provincial district of Taranaki, New Zealand, 220 miles NW. of Wellington by rail. Two miles from the town extensive harbour-works are in progress. Pop. (1886) 2693; (1891) 7932.

Newport, since 1891 a county borough of Monmouthshire. The capital town of the ancient county of Monmouth and Usk, a parliamentary borough, is seated on the river Usk, about 4 miles from its mouth, 24 miles SSW. of Monmouth and 145 W. of London, and it is one of the principal outlets for the produce of the extensive coalfields and iron and steel works in the vicinity. The shipping trade has been very much increased, and with it its dock accommodation, which now covers more than 80 acres. Newport is the largest iron-exporting port in the kingdom, and ranks third amongst the coal-exporting ports. In some years 5,000,000 tons of coal are exported, and 36,000 tons of iron pyrites and manganese imported. The town has many fine public buildings, prominent amongst them being the town-hall (1853), erected at a cost of £30,000, and St Woollos' Church, occupying an elevated site, and in style partly Norman, partly Perpendicular. With its shipping trade, Newport has manufactures of iron, rubber, gutta-percha, and railway and telegraph plant and engines, whilst several important brass and iron foundries are in operation, as well as breweries and pottery works. On 4th November 1839 the town was the centre of a Chartist out- break, which resulted in the death of ten persons, and the wounding of many more. Pop. (1801) 1097; (1881) 38,427; and in 1891, when it was created a county borough, 54,707.

Newport, a market-town of Shropshire, on the Shrewsbury Canal, 11 miles WSW. of Shrewsbury. Chartered by William the Conqueror, A.D. 1075, and it has a 15th-century church, a grammar-school (1656), and manufactures of machinery and agricultural implements. Pop. of parish, 2675.

Newport, the capital of the Isle of Wight, on the navigable Medina, near the centre of the island, 43 miles S. of Cowes and 10 SW. of Ryde. The church of St Peter, 1854, is on the site of one nearly 700 years old, is a fine Decorated edifice, and contains Marochetti's beautiful monument, erected by Queen Victoria in memory of the Princess Elizabeth, who died at Carisbrooke Castle (q.v.) on 8th September 1861. Newport was, in 1810, a town-hall (1810); a free grammar-school (1612), the scene in 1648 of the protracted but fruitless negotiations between the parliamentary commissioners and Charles I, to whose secret 'engagement' a
year before with the Presbyterian Scots the town also gave name; a girls’ endowed school (1761); a diocesan school (1860); and a literary institute and museum. To the north-west are a reformatory (1838) and barracks (1798). A municipal borough, Newport returned two members to parliament till 1867, and then one till 1885. Pop. (1881) 1937; (1891) 10,216.

**Newport**, a town of Fife, on the Firth of Tay, 11 miles by water S.S.E. of Dundee. It has a small harbour designed by Telford (1822), and municipal buildings (1890). Pop. (1891) 2311; (1891) 2545.

**Newport**, (1) capital of Campbell county, Kentucky, is on the Ohio, opposite Cincinnati, and at the mouth of the Licking River, which separates it from Covington; both rivers are crossed by bridges, and there is also a steam-ferry to Cincinnati. The city contains large rolling-mills, a foundry, bolt-works, tile-works, and several steam-mills. Pop. (1890) 24,918; (1900) 28,301. — (2) A port of entry and one of the capitals of Rhode Island, on the west shore of the island of Rhode Island, in Narragansett Bay, 5 miles from the ocean, and 69 miles by rail S. by W. of Boston. It has a deep, excellent harbour, defended by Fort Adams; and there is a United States torped station on an island in the harbour. It contains a brick state-house, a custom-house, a city hall, and beautiful public and private villas, and large hotels; it is noted for fine scenery and sea-bathing, and is one of the most fashionable watering-places in America. In Tonno Park stands the ‘Round Taver,’ or Old Stone Mill, which suggested Longfellow’s poem, *The Skeleton in Armor*. Further north is an inland city, containing 30 large, a brass-foundry, lead and fish-oil works, &c. It was settled in 1638 by eighteen adherents of Roger Williams, and was an important commercial town prior to the Revolution, which affected its ruin and transferred its trade to New York. Newport was the residence of Bishop Berkeley. Pop. (1890) 15,693; (1900) 22,034.

**Newport-Pagnell**, a market-town of Buckinghamshire, at the influx of the Ouse to the Ouse, 56 miles by rail NNW. of London. Named from the Pagans, who owned the manor in the days of Rufus, it was taken by Essex in 1643, and held two years later by Sir Samuel Luke, the protomartyr. At the close of the 18th century the present church, restored by Street in 1838, is the principal edifice; lace-making has declined. Pop. of parish, 3836. See its *History* by Staines (1842).

**New Red Sandstone**, the name formerly given to the great series of red sandstones which occur between the Carboniferous and Jurassic Systems. The sandstones are now divided into two groups, the lower of which is assigned to the Paleozoic (see PERMIAN SYSTEM) and the upper to the Mesozoic System (see TRIASSIC SYSTEM). The term New Red Sandstone is used as synonymous in England with the Trins.

**New River**, an artificial cut, running 38 miles southward from Chadbwell Springs in Hertfordshire intersecting the river Lea near Waltham. It was designed for the water-supply of London, and completed (1609-20) at a cost of £500,000 by Sir Hugh Myddelton, goldsmith, who died poor on 10th December 1631. The seventy-five original shares, sold for £100 apiece, sell now at the rate of £25,000.

**New Ross**, a market-town and river-port of Leinster, Ireland, situated on the Barrow, partly in the county of Kilkenny, but chiefly in that of Wexford, 92 miles S. by W. of Dublin and 15 NE. of Waterford. The two portions of the town are connected by an iron swing-bridge (1869). Before the union New Ross—Old Ross lies 5 miles to the east—returned two members to parliament, and down to 1885 one. It was founded by the daughter of Strongbow, and was formerly fortified. The port can be entered at spring-tides by ships of 800 tons, and at all times by vessels of 200 tons; and there is communication by river and canal with Dublin and Limerick. Pop. (1851) 1981; (1881) 6670; (1891) 5847.

**Newry**, a seaport and parliamentary borough, mainly in County Down, but partly in Armagh, on the Newry River, 38 miles SSW. of Belfast by rail. A canal connects it with Carlingford Lough and with Lough Neagh. The town is handsomely and pleasantly situated, and the new town and the new harbour. The trade is with Glasgow and Liverpool in cattle and other agricultural produce. Flax spinning and weaving, with rope and sail making, tanning, and granite-polishing, are the industries. The place dates from 1131; its castle was taken by Edward Bruce in 1318. Newry returns one member to parliament. Pop. (1851) 13,191; (1881) 15,590; (1891) 13,605.

**New Shoreham**. See Shoreham.

**New Siberia**, a group of uninhabited islands in the Arctic Ocean, lying off the coast of Siberia between the mouth of the Lena and the mouth of the Indigirkas. The principal are Kotelnoi (the largest), Lakhhov, Fadeyev, and New Siberia. The coast is rocky, and ice-bound all the year round. The climate is cold, with short, very cold winters, and long, very cold summers. The natives use reindeer, foxes, and seal. Ivory, bone, and whalebone are brought to trade. There are no mammals, and the birds are few and small. There are no plants.

**New South Wales** is the oldest colony of Australasia. It formerly included what is now known as Queensland, New South Wales, Victoria, South Australia, Tasmania, and New Zealand, all under the government at Sydney. The area has diminished to 310,700 sq. m., or 193,848,000 acres, being five times that of England. It has the Pacific to the east, from Point Danger, 28° S. lat., to Cape Howe, 37° S.; South Australia to the west, along the meridian 141° E.; Victoria to the south, by the Murray River; and Queensland to the north, from 29° S. lat., a series of mountain-chains, from 20 to 100 miles distance from the sea, extend from near Cape York to the Australian south-east coast. The southernmost are the Australian Alps, running south into Victoria, culminating in Mount Kosciusko, 7350 feet high. Between these and the Blue Mountains, west of Sydney, with peaks 4000 feet, and containing the Jenolan Caves (q.v.), Liverpool Range is more northerly; and the New England hills, north-east, rise 5000 feet. With the exception of some isolated mountains, the region to the west consists of vast plains, up to the Barrier Ranges near South Australia. The mountains give birth to short and rapid streams toward the sea, but long and sluggish ones westward. The Hawkesbury or Nepean, Hunter, Clarence, Shoalhaven, and Macleay are eastern: The Lachlan, 700 miles long, runs into the Murrumbidgee, which flows 1350 miles before falling into the Murray. The Murray, after 1100 miles on the New South Wales border, passes into South Australia. The Darling, rising in Queensland, is more than 1000 miles north of the Murray, and runs north-eastward, and, after reaching the Murray, the main receptacle of the country’s waters. The Macquarie and Namoi go northward to the Darling. The dry interior has few streams. Among the few lakes are George, Bathurst, Hlrawar, Macquarie, and Briannah. The western end of the interior, the Illawarra, is also well watered. Port Kembla Bay is now far from Cape Howe. North of it are Jervis Bay, Botany Bay, Port Jackson, Broken Bay, Port Hunter, Port Stephen, Port Macquarie. The capital, Sydney (q.v.), is on Port Jackson, and is the headquarters of the Australian naval squadron. Near it are Windsor and Parramatta. Newcastle and Maitland are by the Hunter River. Goulburn
and Bathurst are westward, Albany and Wentworth on the Murray, Bourke and Wilcannia on the Darling; Wellington is on the Macquarie, Wollongong by Illawarra, Demi-lignon in Riverina, Silverton in the Barrier Ranges.

The colony was established in January 1788, under Governor Phillip, with a party of transported prisoners from England, as the former place of exile, America, was closed by the independence of the thirteen states three years later, to the much want of food. The introduction of free colonists, to whom grants of land were given, promoted pastoral and agricultural pursuits; and the change from despotism to responsible government was gradually made. The cessation of transportation in 1840 was followed by social and political advances; and the gold discovery in 1851 gave a great impetus to the search for minerals. Town industries were developed; and commerce was aided by a fine harbour, an excellent mercantile marine, and the extension of railways.

As regards flora, and the eucalyptus-tree prevails in the colony, but acacias also are common, and pines and cedars, as well as palms in the north-east. Forest preservation is now receiving official attention. In addition to products of native vegetation, plants of commercial value are being introduced, adapted to the various soils and climates of the colony.

Of 1000 economic plants in the colony, 210 are useful for food, 156 forage, 123 drugs, 57 oils, 87 tans, 60 gum-resins, 39 kinos, 14 perfumes, 35 dyes, 67 fibres, 630 timber. Some of these are available for export. There are more flowering plants than in all Europe.

The fauna, as in the rest of Australia, consists mainly of marsupial animals. In a single year there have been killed, as nuisances, 1,310,900 marsupials. Birds are of great variety, many of them of economic importance; and pelagic notes. Insects are numerous, and not always welcome. Lizards and snakes may run to a good size, but there are no alligators. Fish, especially in the bays, are plentiful.

Geology.—Silurian and Devonian formations, with granite, igneous, and metamorphic rocks, are rich in gold, silver, lead, copper, tin, and other metals. The hilly country forms the system of mining industry, but the older rocks underlie the Tertiary and Post-Tertiary beds of the vast plains to the westward. This is seen in both Palaeozoic and Mesozoic strata. The Cretaceous and Jurassic rocks are confined to the north-west corner. Trappine eruptions are of various geological epochs; yet the colony has fewer recent volcanic, though extinct, craters than its Victorian neighbour. Marsupian remains of huge dimensions are observed in the Pleistocene formations. Besides the monsters Diprotodon and Nototherium, there are the marsupial lion Thylacoleo, and the Thylacinus. In the Pleocene and Pleistocene are the alluvial gold workings and the diamond and tin washing places. For six months of each year, the ranges, Mesozoic ones are nearly confined to the eastern side, north and south of Sydney, as the Sydney sandstone, and in the Clarence basin.

Gold, known in 1823, was first worked in 1851, near Bathurst. It is found over an area of 79,000 sq. m., in granite, porphyry, diorite, quartz, breccias, and alluvial deposits. Dry blowing is employed by miners where water is scarce. Gold is often mixed with silver, copper, or tin; and the ore is won by the water-washing, paying 70 to 92 shillings an ounce. The output to the beginning of 1890 was nearly £38,000,000, though only £434,070 in 1889. Silver, found at Bourke, Sunny Corner, &c., abounds in the Barrier Ranges near South Australia, at Silverton, Thackaringa, &c., where there are over 4000 miners. Discovered in 1863, in an almost rainless region, the silver area is 100 miles by 12. One company paid in dividends £2,676,000 up to 1880, having raised 161,500 tons of ore, yielding 6,300,000 ounces and 8,700 tons of lead. The district up to 1890 produced £4,168,387; the Broken Hill Company has raised 20,000,000 ounces; and in 1889 the product of silver for the colony was £1,971,198.

The first gold was found in 1851, yielding £212,444 in 1859; its ore being known as 'Canny over.' A deposit opened in 1872, from streams and lodes in granite, has fields of equal area, with a yield for 1889 of £207,670. Lead is chiefly got from silver-mines. Antimony, manganese, bismuth, &c., are mined. Iron is abundant, but not profitable to work owing to the cost of labour. Precious stones, as the diamond, emerald, zircon, sapphire, topaz, &c., occur in granite localities. Asbestos, zinc, mercury, cobalt, and alum are exported. Graphite, kaolin, and building-stone enrich the colonists. Coal is the most valuable mineral of New South Wales. It extends over 24,000 sq. m., £22,000,000 worth was raised during 1860-80; and the export of 28 million tons brought in £16,000,000. In 1894 the gold produced was worth £1,156,717; the silver, £249,150; copper, £283,817; and coal, £1,155,574. Kerosene is also produced in large quantity from the shale of the Blue Mountains.

The pastoral resources in 1895 include as many as 56,917,270 sheep (in spite of recent losses of 5,000,000 from drought); cattle, 2,465,411; horses, 518,181; swine, 2,753,591. Most of these animals are upon stations or runs, on land leased from government, sometimes at less than a penny an acre rental in the dry west. The leases are for twenty-one years in western divisions, ten in central, and five only in eastern, at a higher rent. The lessees are the wealthiest men in the colony, and the chief source of wealth. The gold rent from England in 1865, was in use, as there were no native sheep, cattle, or horses. The sheep imported from Bengal and the Cape were hairy, but the wool was improved by the introduction of Spanish merinoes; the cattle also were improved, and have been introduced. Wool exported in the year exceeds two hundred million pounds' weight.

Agriculture occupies far less land than pastoral, but while 140,000,000 acres produce a rental of £2917,150, being devoted to flocks and herds, there are but £1,740,000 on land leased from government, and £1,000,000 on land owned, inhabited, devoted to culture, and nearly one-fourth of that is laid down in artificial grasses. But farming ground, especially near towns, is very valuable. Some of this is freehold, bought at government auction sales, though formerly bestowed in grants at a nominal quit rent. Much is leasehold, held at various rentals on terms of years from the state, till the full purchase is thereby effected. Of 46,197 holdings, 580 were over 40,000 acres each, and 6889 were under 15 acres. The lands are graded from New England to the coast, a country easy to settle on. The country, however, is more pastoral than agricultural, growing less produce proportionately to its size than Victoria and South Australia. In March 1890 the area under crop was 947,572 acres, but 47,920 holdings contained 41,042,250 acres. In 1890 the crop consisted of 676,400 tons in wheat, averaging 15 bushels to the acre; 173,330 in maize, averaging 304; 5440 in barley; and 787 in vines; but, of various kinds, 222,262 sugar-cane, 18,730; oranges, 9894; tobacco, 3239; orchards, 16,867; market-gardens, 5490; potatoes, 17,561. Yet, till the colony exported £2.676,350 of agricultural produce in 1889, it imported £5,548,915.

The sugar-plantations in the north-east are not so productive as in Queensland; nor are the apple-orchards and potato-furrows equal to those of
Tasmania. Not all the fruits that thrive in England and Italy grow here.

Climate influences vegetation in the colony. Farming facilities exist in the Dividing Range, the highlands of New England in the north-east, and the alpine soil of the Throsby ranges. The volcanic soil and its associated heavy rains and heavy snows may be experienced on the lofty plains; but Sydney, 33° 50' lat., had snow in thirty years. Though in summer the thermometer might rise to 100° and beyond during the day, the nights are generally cool and recuperative after the heat.

The trade exceeds that of any of the neighboring colonies. It was worth £4,157,091 in 1889—£22,863,657 in imports, £23,294,334 exports. Each averaged over £20 a head, or about £16 in produce of the colony. The imports amounted to £25,670,422, and the exports to £22,991,171. The Queensland trade was £6,415,553; the Victorian, £7,304,388; the American, £2,225,296; the German, £1,032,517; the French, £294,604; the Indian, £20,533. The total trade exceeded £10,070,189. New South Wales imported £2,164,206 of drapery; £1,040,146, apparel; £282,304, iron and machinery; £741,189, flour; £460,380, spirits; £363,633, teas; £438,694, beer; £220,736, tobacco. Of exports, the home produce was £24,423,311; the Tulare, £1,591,380. The total value of British and foreign products realised £7,300,520; minerals and metals, £1,035,776; live-stock, £1,715,797; and coal, £1,319,271. The colony's wool of 1889 brought £10,620,636. Duties are only levied on forty-seven subjects; there are none ad valorem, what is practically free trade having been established in 1872-79. The customs realised £1,095,885 and excise £201,371. There entered, in 1889, 2,354 ships of 2,632,081 tons; departed, 3229, of 2,689,098. Of the tonnage, 4,659,785 was British; 661,381, foreign. Of the former, 2,817,071 were colonial; of the latter, 1,841,714. Of the total, London cleared 5,284,149 tons, and Liverpool 4,758,925, Sydney cleared 1,432,340, and the Newcastle coal-port, 1,126,892. The railways connect New South Wales with South Australia, Victoria, and Queensland. The 25,000 miles belonging to government railways in 1885, cost £30,011,365. Total imports in 1889 were worth £15,801,941; the total exports, £29,577,673.

Government.—The governor is appointed by the Queen. The executive is of 10 ministers; the Upper House or Legislative Council hold, in 1892, 75 life members; the Lower, or Legislative Assembly, 141 members, in 74 electorates, receiving £300 a year. The parliament is triennial. The revenue in 1892 was £71,682; in 1890, £61,317,121. From taxation was raised £5,783,750; from land, £2,298,639; from postal, telegraphic, and other services, £4,136,590. The public debt, contracted for useful works, was £48,578,837 in October 1889. An excellent volunteer force comprises some 3500 men. In 1885 a New South Wales contingent was sent to strengthen the British forces in the Sudanese war. The national brigades. The wealth of the colony is stated at £314 per head, that of the United Kingdom being £270.

The population (1891), 1,132,207, of whom 518,199 were female, included 14,156 Chinese and 1997 aborigines. The ports, farming localities, and mining return seven-eighths of the people. About 3000 manufactories employ 49,238, wages for eight hours a day being from 8s. to 12s. The birth-rate is 33[1/4] per thousand; marriage-rate, 67; death-rate, only 13[1/4]. In religion, the Church of England claims one-half the population, the Roman Catholic nearly one-third; but returns for 1889 gave Sunday attendance at worship as follows: Roman Catholic, 83,919; Church of England, 84,900; Presbyterian, 33,247; Salvation Army, 14,423; Congregational, 13,660; Baptist, 1925.

Public schools are now unconnected with churches, and no state aid is granted to a denominational school; but one hour a day may be devoted to religious instruction in state schools, where parents present no objection. On the roll in 2961 schools are 229,043 pupils. The annual cost to the government of each child is £4 14s.; the fees bringing in 1925 so that there are many private schools. The Church of England has 36,342 children in Sunday-schools; Roman Catholic, 25,820; Methodist, 29,383; Presbyterian, 12,054. There are technological, industrial, and general museums, picture-galleries, public libraries, schools of arts, and mining schools; and a number of private universities, seminaries, and affiliated colleges, crowns the educational edifice.

Trollope, New South Wales (1852); Church of England and Statistical Account of New South Wales (1875); G. W. Griffin, New South Wales, her Commerce and Resources (1888); T. A. Ceglan, The Wealth and Progress of New South Wales, 1889-90 (Sydney, 1890); G. B. Barton, History of New South Wales from the Records (16 vols. 1890 et seq.).

Newspaper, a sheet of paper printed and distributed at short intervals for conveying intelligence of passing events. This is a definition of a newspaper which might safely be employed for legal purposes; but it is altogether inadequate to describe the great function which is now, in all parts of the civilised and semi-civilised world, at once the bearer of tidings, the herald of commerce, and, according to the predilections of its readers, a more or less accepted guide in matters of politics, theology, morals, arts, and sports.

The oldest newspaper of the world is (1891) estimated at 41,000, of which 24,000 appear in Europe. A further division, according to stricter geographical limitations, shows that Germany leads the list with 5500, then comes France with 4100, Great Britain and Ireland with 4000, Australi a-Hungary with 2500, then Russia with 850, Sweden with 750, Belgium and Holland with 300 each. The rest of European newspapers are published in Portugal and the Scandinavian and Balkan countries. The United States of America must be credited with 12,500 newspapers. Canada claims 700, and Australia about the same number. Of journals issued in Asia, Japan alone has 200. Africa has 200 newspapers, and the Sandwich Islands three. Having regard to the respective popularity of the languages employed in the following list, of 17,000 newspapers they have been published in English, 7500 in German, 6800 in French, 1800 in Spanish, and 1500 in Italian.

The newspaper came into existence when accounts of the imperial armies of Rome were sent to the generals in command in all parts of the empire. The first newspaper was called la voce dei soldati. These Acta Diurna were communicated by the generals to the officers under their command, and thus the foundation of a system of newspaper circulation was laid. It is to Germany that we have to look for the beginnings of modern European journalism. As early as the 15th century small newsbooks were published in Augsburg, Vienna, Ratisbon, and Nuremberg. It was not until 1566, however, when the official
Notices Scritte were established at Venice by order of the Venetian government, that a new sheet at all answering to present ideas was produced. At first they were not printed but written out, and exhibited in various public places, any one being permitted to read them on payment of the small coin called a gazetta. From this these journals acquired the name of gazettes, and so great was that it became necessary to print them. Gazettes were soon afterwards issued in most of the leading cities of Europe.

Setting aside the apocryphal history of the English Mercury, said to have been published in 1641, and the London Advertiser, a Weekly News of 1622, edited by Nathaniel Butter, is, so far as positive evidence goes, the first English newspaper, as we understand the term. The London Weekly Courant made its appearance in the same year. Twenty years later what has been called 'the era of the Mercuries' was entered upon, and Mercuries of many kinds claimed public patronage,—amongst others the Mercurius Clarus, started in 1641 in the interests of the clergy; the Mercurius Britannicus (1642); the Mercurius Citi- ceni (1647), a weekly newspaper printed and partly engraved on wood of Charles I. and Sir Thomas Fairfax; the Mercuria Politica, published in London, and reprinted in Scotland for the entertainment of Cromwell's army; and the weekly Mercurius Coelestinus, the first strictly Scotch newspaper. All these were begun for a penny, and was the penny-duty, which was repealed in 1691, leaving British journals free from imposts of any kind.

In spite, however, of the heavy burdens against which they had to struggle, through nearly the whole of the 18th and a great part of the 19th centuries, newspapers gradually increased in their circulation, influence, and exercised much power in the directing of public opinion. In all the chief centres of population in the provinces, as well as in London, papers of importance were established. The first half of the 18th century saw a striking extension of journalism in Britain. In the metropolis there was, in addition to the Courant, the London Daily Post and General Advertiser, established in 1726. This changed its title in 1732 to the Public Adver- tiser, and attained celebrity as the medium through which the laws of the provinces were brought to the world. Defoe's Review of the Affairs of State, begun while the editor was in prison, existed from 1704 to 1713. The St James's Post and the St James's Evening Post, started as distinct journals in 1715, were by amalgamation as the St James's Chronicle-Herald, started in 1718, as long existence of any kind. The Morning Chronicle, started in 1770, the Morning Post in 1775, and the Morning Herald in 1781, the Times (q.v.)—the chief and central figure of modern journalism—was started in 1785, as a development of the Daily Universal Register, which had existed from 1785.
Mr John Walter was the originator and sole owner of both papers, and mainly through his energy and ability did the journal ultimately attain its position of pre-eminence. In the literary direction of the paper he always employed the highest available talent, and the periodical has been affected by various improvements. In 1814 he succeeded in printing the Times by steam-power.

The publication of the leading London and provincial newspapers involves an immense outlay, and the co-operation of an army of experts representing the different departments of literature and journalism. The work is now divided and subdivided in such a way that it is difficult to describe its organisation on the lines of the old official designations. It is no longer possible to speak unreservedly of an 'editor-in-chief' as having necessarily supreme power as the representative of the proprietors. So numerous and so various have the duties of that office become that it is, so to speak, frequently 'put into commission.' It is not uncommon to find a managing editor whose business is to control in every way the supply of news, including foreign correspondents. The adjectives of all kinds of reports are in the hands of editors who control the general policy of the paper, and is responsible for the style and substance of all original matter. It is increasingly rare to find an editor who writes any one of the several leading articles with which most of the great dailies furnish their readers. Each of them has a staff of leader-writers, who are often well-known workers in literature outside of journalism. On the principal newspapers the leading-writing staff includes experts of the highest mark, who are paid retaining fees in order that they may be in readiness for the necessary essay on the subjects of which they are masters. For the leaders themselves they are paid special fees. A similar system prevails with respect to special correspondents, whether employed in a military or social capacity. George Borrow was the first war-correspondent, writing for the Morning Herald in 1839. Some of these gentlemen receive what Mr G. A. Sala has described as 'the wages of an ambassador,' in consideration of being always prepared to start for a campaign in 'Darkest' Africa, or to report the progress of that service rendered in return involves much personal danger is sadly suggested by the memoirs of St Paul's to the war-correspondents who fell in the Sudan. The sub-editors vary in number, according to the combinations of the participants. The duties of the sub-editor on all important newspapers, whether metropolitan or provincial, have been almost revolutionised during the last four decades of the century. It is true that on the evening papers it is still necessary that the sub-editors should make a special study of the morning papers of the current date. This indeed enables the evening, or more properly speaking the afternoon, journals to appropriate the most interesting telegraphic items within a few hours of their appearance in the morning papers, to which they have access along with the general public, where they have caused a heavy expense. It may be noted that in some of the British colonies a few already exists giving copyright of 'exclusive' news for twenty-four hours after publication. On the whole, however, the sub-editor has almost ceased to be a glamorous person; which is, indeed, well accounted for by his colleagues. The old-fashioned scribe at the conectors of newspapers, that they 'put in anything to fill up,' is now only an amusing anomaly. Such are the 'services' of news which a daily paper is obliged to employ—whether they be those of the Press Association, the Central News, the Central Press, the Exchange Telegraph Company, Reuter's, or Dalziel's—that a sub-editor's trouble in leaving his work is to reconcile the amount of 'flimsied' matter which he has put into the waste-paper basket with his duties to his chief.

Reuter's Agency was founded in 1858, the Central Press in 1861, the News Association in 1868, and the Central News Agency in 1870.

There used to be twelve or sixteen parliamentary shorthand reporters on every London daily. At that time the daily provincial papers obtained their telegraphic reports of parliament solely from one or other of these organisations. This is now changed. The chief papers in the provinces have formed syndicates in accordance with their respective policies for the purpose of obtaining special reports of the debates from their own associated staffs of reporters. This arrangement, which parliament sanctions, enables the leading provincial dailies to supply parliamentary reports according to their own special requirements, the result being that debates are frequently reported at greater length in those papers than in the London journals of the same date. Thus it arises that the chief provincial papers have offices in the neighbourhood of Fleet Street or the Strand, where a special wire or wires will connect the London and the country offices. Formerly the journalists who were in charge of these wires were styled the 'wire men;' now they are designated London editors. In the city these journalists are often of the highest and most influential, and are the furnishing of information connected with financial matters to various papers. The chief London daily retain the exclusive services of a city editor, while several provincial journals, published in different localities, are served by one and the same man. They are thus enabled also in a modified degree to colonial and even foreign newspapers, which often have their own special services of news, and special representatives, in London and other principal cities.

Another important representative of modern newspaper enterprise is what is known as the London correspondent. There were London correspondents of a kind even in the days of the Restoration, but it was not until 1863 that the "London letter," as it is now known, was introduced as a special service of financial papers. In that year the Central Press Agency began to send to the financial experts on the floor of the House with 'a London letter once a week, written by a gentleman of long standing in the literary world.' This was the late Edward Spender, who for several years continued to write what formed an admirable combination of political, social, and literary gossip for country readers. A time went on the weekly letter became a daily contribution, and other London correspondents entered the field, until now the London letter is an indispensable feature of all provincial journals. Many well-known journalists are engaged in this work, including several members of parliament, and the lobby of the House of Commons forms their chief hunting-ground.

In 1843 the number of newspapers published in London was 79; in 1880 it was about 340; in 1880 it had become 1160. Of these 1160 daily and 90 of which are issued in the evening (nominally), their first editions being issued about noon. The price of these papers is either a penny, or, as in the case of the Daily Mail (1896), a halfpenny; the Times continues to be published at a premium. The list of dailies which are published has not amounted to a hundred in the course of almost entirely of all political journals, but during recent years has increased by the appearance of several daily sheets devoted exclusively to financial and commercial matters. Financial journalism, indeed, forms a very special feature of modern journalism, and enterprise. The Economist, established in 1843, and a few other weeklies of kindred aims, held this
In the following analysis of class and trade journals it has been found practically impossible to differentiate the papers properly so-called and other periodicals. Occasionally, too, a journal will appear under more than one classification. The distribution of papers according to subjects, however, may be thus distinguished: Accountants, 2; agents, 3; agriculture, 30; authors, 18; bankers, 2; bakers, 2; bankers, 1; Baptists, 11; bees, 3; bibles, 1; booksellers, 9; boot and shoe trades, 2; botany, 2; boys, 6; brewers, 4; builders, 13; building-societies, 2; butchers, 1; carpenters, 11; carriers, 3; chemists, 2; chemists and druggists, 10; chess, 3; Church, 47; civil service, 8; coach-builders, 2; coal trade, 2; colonies, 21; comic, 30; commercial, 41; confectioners, 5; contracts, 4; co-operation, 4; country, 7; county courts, 1; cow-keepers, 1; elevation, 5; dogs, 5; drama, 13; drapers, 4; dyers, 1; education, 23; electricity, 6; engineering, 10; entomology, 1; estates, 7; exchange, 4; fashions, 57; financial, 39; fire, 2; fishing and fish-trades, 4; food, 3; food, 12; furniture, 6; furriers, 1; friendly societies, 4; Friends (Society of), 3; fruit trades, 2; furniture, 8; gardening, 16; gas, 3; geographical, 2; geology, 1; German, 2; grocers, 9; gynecology, 1; hairdressers, 2; hardware, 1; hatters, 1; homoeopathy, 2; horology, 2; horses, 2; hosiers, 3; hospital, 1; implements, 1; India, 6; India-rubber, 1; insurance, 18; inventions, 3; iron and ironmongers, 7; jewellers, 1; Jewish, 4; labour, 4; laundry, 3; law, 18; leather, 5; licensed victuallers, 6; lifeboats, 1; literary, 18; live-stock, 7; local government, 6; machinery, 2; marine, 3; material, 2; mathematics, 3; meteorology, 1; millers, 2; mineral waters, 4; mining, 3; music, 18; natural history, 6; navy, 14; Nonconformists, 13; non-sectarian (religions), 46; notes and queries, 2; numismatics, 1; official, 2; oil and colour trade, 2; paper trades, 2; pawn-brokers, 1; peace, 1; photography, 10; pharmacology, 2; plumbers, 1; pottery, 1; poultry, 8; Presbyterian, 3; Primitive Methodist, 7; printers, 12; railways, 10; Roman Catholic, 15; saddlers, 3; sanitary, 8; scientific, 6; secular, 3; shipping, 14; shorthand, 3; society, 24; sporting, 40; stamps, 1; Sunday-schools, 6; tailors, 3; typography, 17; temperance, 32; textile industries, 11; timber trade, 2; time-tables, 36; tobacco, 4; undertakers, 1; Unitarians, 2; warehousemen, 3; Wesleyans, 6; wine and spirits, 4; yachting, 1.

The circulation attained at the present day by the leading metropolitan and provincial papers is in some instances very large. The Daily Telegraph and the Standard each circulates close on a quarter of a million copies. Amongst the London evening papers the Star, the Echo, and the Evening News and Post each claims a circulation of 200,000 copies or thereabouts. Of the penny weeklies, Lloyd's Newspaper heads the list with half a million copies, and a further half-million is divided between the Weekly Dispatch and Reynolds's Newspaper. Other London weeklies with vast circulations are the Police News; the Territorial; the Graphic, with the Sketch, Graphie, and Black and White.

In the provinces there are the Yorkshire Post, 45,000, the three Manchester morning papers (with a combined issue of at least 100,000), and the Birmingham Post, 30,000—amongst the morning dailies; and a glance at the list of provincial weeklies shows us the Sheffield Weekly Telegraph, 215,000, the Glasgow Weekly Mail, 290,000, the Dundee Weekly News and People's Journal, 200,000, the Newcastle Weekly Chronicle, 100,000, the Manchester Weekly Times, 100,000, and the Sunday
NEWSPAPER

Chronicle (Manchester), 290,000. It should be mentioned also that since 1882, when Tit-Bits was started, there have sprung into existence a large number of journals which are neither strictly newspapers nor magazines, but are widely popular. Tit-Bits was the first of this class, with 12,500 copies per week. Following in its train are such papers as Answers, Pearson's Weekly, &c., all of which sell largely.

As already mentioned, the newspaper press of Scotland had its origin during the civil wars of the 17th century. The Publick Occurrences, printed at the press of Cromwell's army, being employed to reprint the London Mercurius Politicus for the benefit of the troops then in Scotland. This issue was continued from 1653 to 1669; in which latter year the Mercurius Politicus was published for the last time, and after three months, and being succeeded by the King's Intelligencer. In 1669 came the Edinburgh Gazette, in 1702 the Edinburgh Courant, in 1706 the Scots Courant, and in 1718 the Edinburgh Evening Courant.

In 1728 the London Gazette was started by the Welsh Clansman, which was started by the Society for the Protection of the Welsh Clans. The Clansman, which was started in 1728, was the first Irish newspaper properly so called. A Dublin daily, called Poc's O'Occurences, ran from 1700 to about 1750; and Faulkner's Journal, another Dublin daily journal, was started in 1728. Saunderson's Journal, established in 1746, existed down to 1793. The Dublin Evening Post was first issued in 1725; and in 1727 the Belfast Newsletter, the oldest existing Irish newspaper, was started. The Derry Journal was established in 1772, the Limerick Chronicle in 1763, and the Belfast Northern Whip in 1824.

The English papers of the principality of Wales show that the demand for a public of a public demand which every year becomes more exacting. In the northern division, a thinly-spread population have still to be content with weekly papers — Welsh and English — with the addition of such daily supply as is afforded by the Liverpool press. The Wales, a weekly journal, which the masses cling to the native language enables the Baner of Denbigh to hold a commanding position among the newspapers of North Wales. A different condition of things obtains in the busy centres of South Wales, with its vigorous industrial life and populous communities. Two daily papers share the patronage of the South Walian. The Western Mail, a progressive Democratic-Conservative journal, is the senior in point of age. The South Wales Daily News is the organ of the advanced Liberalism professed by the majority of South Wales electors. Both papers are published in Cardiff. Each populous district has its local journal, and the vernacular press is supported by a large, but diminishing, class.

In the different British colonies newspaper enterprise has been very active in recent years. As far back as 1717, the Pennsylvania Gazette, founded for by the Sydney Gazette and New South Wales Advertiser, which was published 'by authority.' The Australian, also issued in New South Wales, was originated in 1824, but succumbed in 1848. In 1821, however, the Sydney Morning Herald was established, and has long held the position of being the most substantial paper in the colony. In Victoria the Melbourne Advertiser was the progenitor of the existing race of Victorian journals. At first it was written, not printed, and had a circulation of not more than a dozen copies at sixpence a copy. It ceased with its thirty-second number. The Melbourne Advertiser was reputed to have the largest circulation of any in Australia — now hold the first rank. South Australia has in the Register a journal which has been published daily since 1850. There are not more than about a score of journals in Western Australia, the number including three daily. The Western Australian is the patriarch of journalism in Queensland. There are two other daily papers in Brisbane, and about seventy papers altogether in the colony. In Tasmania the newspaper press began to have a large existence in the year 1830, with our own colony, and about twenty others. In New Zealand there are no fewer than fourteen towns which have daily papers, besides more than a hundred other journals published throughout the island.

In the South African colonies the Cape Times, although it only appeared during the last quarter of the 19th century, has left a lasting impression. The Cape Mercury, published three times a week, was established in 1875 in King William's Town. Natal has three daily papers and many weeklies. In the Gold Coast, Lome, and Asmara, all its British Guiana (which has a daily paper at Georgetown), and the West Indies (with a daily journal in Jamaica) British journalism is more or less well represented. Even Cyprus has its weekly Owl. China claims to have had newspapers before they were known in Europe, and we are specially interested in the three or four English daily papers published in Hong-kong.

In India we find an English press powerful and influential out of all proportion to the extent of its circulation. Every European British subject in India, who has brains and character, is the centre of a social system. To him the newspaper, which constitutes the link between his early home and the scene of his daily labour, is an infinitely more important institution than the British journal is to the citizen of London or Liverpool. The English language, a daily with a public opinion, has made its appearance in 1821, under the title of the John Bull in the East, and had set up at its press the rough proofs of several of Macaulay's best-known essays. There are two other daily papers in Calcutta, while Bombay, Madras, Allahabad, Delhi, Lahore, and Lucknow have each one or more daily newspapers. Many journals are issued in English by natives for native readers, and the sheets printed in the vernacular languages are legion. The small cost of native labour largely aids the multiplication of Indian journals.

United States and Canada.—In 1800 there were issued in the United States and Canada a total number of 17,750 newspapers and periodical publications, consisting of 13,104 weeklies, 2191 monthlies, 1026 dailies, 280 semi-monthlies, 217 semi-weeklies, 126 quarterlies, 82 bi-weeklies, 38 tri-monthlies, and 30 tri-weeklies. The geographical distribution of the 17,750 periodicals is as follows: New York state, 1778; Illinois, 1309; Pennsylvania, 1281; Ohio, 1043; Dominion of Canada, 812; Kansas, 807; Iowa, 799; Missouri, 750; Massachusetts, 683; Indiana, 635; Michigan, 644; Illinois, 528; New York, 522; Minnesota, 408; Texas, 430; Minnesota, 427; New Jersey, 318; Colorado, 268; Georgia, 257; Kentucky, 257; South Dakota, 250; Tennessee, 230; the Territories, 220; Virginia, 220; North Carolina, 192; Arkansas, 187; Connecticut, 182; Maryland, 176; Alabama, 172; Maine, 156; Mississippi, 142; Louisiana, 152; Washington, 146; West Virginia,
NEWSPAPER

143; Oregon, 123; New Hampshire, 126; Florida, 121; South Carolina, 120; North Dakota, 119; Vermont, 83; District of Columbia, 88; Rhode Island, 64; Montana, 38; Delaware, 36; Nebraska, 24. It is estimated that the total issue of a single edition of all these papers represents a circulation of 41,594,000 copies, being an average edition of 2835 copies. According to classification it is found that there are 27 publications with circulations of 150,000 and over, 38 with 10,000 to 25,000; 75,000, and 42 with 50,000; while at the other end of the scale there are 5426 publications classed as issuing only 500 copies per issue. New York prints more than a quarter of all the papers which are said, and Pennsylvania, Illinois, and Massachusetts more than another quarter. Nearly 75 per cent. of all the publications issued appear weekly.

According to an expert statement there were issued in the United States and Canada in 1899 a total of 22,061 newspapers and periodicals, of which 15,088 were weeklies, and 2229 were dailies.

The earliest newspaper published in America was the Publick Occurrences, 1690; this was followed in 1704 by the Boston News-letter, which continued without a rival until 1719, when the Boston Gazette was issued 'by authority.' Later on the News-letter had its title changed, and became the Massachusetts Gazette and Boston News-letter, and was conspicuous for its support of the British rule in the early days of the war of independence, ceasing to exist, however, when the English troops evacuated Boston. In 1721 the New England Courant was established by James Franklin, and subsequently was conducted by his more renowned brother, Benjamin Franklin. The latter started a paper of his own, the Pennsylvania Gazette, in 1729, after the death of the Courant, and this appeared weekly, until 1745, when it merged in the North American Review. The Gazette was for a long time the chief organ of the popular party, and was the medium through which John Adams published his Letters of Novanglus. The Massachusetts Spy was another paper of note on the revolutionary side. On being removed from Boston to Worcester, the title was changed to the Worcester Spy. At the revolution the New England colonies possessed 14 newspapers; Pennsylvania, 9; New York, 4; and the middle and southern colonies, 10. All save the semi-weekly Advertiser of Philadelphia were published weekly. From this period the American journalism was marked by rapid strides; it extended by leaps and bounds, developing an originality all its own, and displaying an activity in some directions altogether out-distancing the achievements of Great Britain.

What the journalistic enterprise of the North American continent represents has already been indicated; it is desirable, however, that some of its more salient features should be referred to. American papers have always been more frequent than anything else. The number of American newspapers is shown in the sensational manner, and vents its views and opinions with what an English journalist would regard as a reckless unrestrained. The organisation and equipment of the leading papers of the chief cities are most complete, including an editorial and reporters' staff of sufficient size to constitute a proprietory of remarkable vigour and enterprise. The great majority of American and Canadian papers are, of course, printed in English, but there is a considerable number published in other tongues. Those published in the German language number 724, while 112 are in French, 59 in the Scandinavian languages, 34 in Spanish, 16 Bohemian, 12 Dutch, 7 Polish, 8 French, 5 Italian, 2 Portuguese, 2 Chinese, and 2 Hungarian.

The principal newspapers of America and Canada have a world-wide renown. The Herald, originatied by James Gordon Bennett, the Tribune, founded by Horace Greeley, the World, the Times, the Sun are the chief papers of the great cities of Boston, Baltimore, Cincinnati, Philadelphia, St Louis, San Francisco, and other cities there are journals hardly less famous. Amongst the chief Canadian papers may be mentioned the Toronto Globe, which claims to be the leading paper of the Dominion, the Montreal Herald, the Quebec Morning Chronicle, the Ottawa Free Press, and the Ottawa Citizen. There is a considerable sprinkling of Canadian papers printed in French, the chief of them appearing in Quebec and Montreal. The Sunday paper has long been a specially popular institution in America. Nearly every prominent daily in the States issues its enlarged Sunday edition, which in addition to its news proper contains a vast amount of miscellaneous reading, culled from all kinds of sources, and often including special contributions of great merit. In Canada, the Sunday paper is not so common. In some of the large cities of South America, also, as in Rio de Janeiro and Buenos Ayres, there are ably conducted English newspapers.

France.—Journalism in France began with the Gazette in 1631. The first French daily paper was the Journal de Paris, started in 1777. Many journals sprang into existence with the Revolution, but most of them had but a brief career. Under the first Napoleon the freedom of the press was much restricted. It was then that the danger of standing papers was most felt. Napoleon suggested the filling of a large portion of the sheets with the Feuilleton (q.v.). There are at present about 44 daily papers (morning and evening) published in Paris alone. As newspapers, in the full sense of the phrase, the journals of France cannot be compared with those of Great Britain. They contain less matter, and they do not, as a rule, report with any degree of fullness home or foreign events. The Temps, which is said to have a circulation of 45,000 per day, approaches somewhat to the English standard; but the Figaro, which, with its singular mixture of crassness and elegance, would be considered frivolous in England, has a circulation of 100,000 daily. French daily papers generally cost at least twice as much as English ones. A notable exception, however, is found in Le Petit Journal, an evening paper costing 5 centimes (one halfpenny), which has probably the largest circulation of any paper in the world; it is put down at 950,000. See also Galignani.

Belgium.—An illustrated war-gazette called the Nieuwe tijdighe was the first journal published in the Low Countries, in 1605, and it succeeded the Gazette des Provinces, which survived until 1805. The Belgian newspapers are now numerous, including about a dozen daily journals in Brussels, and half that number (mainly in Flemish) in Antwerp. The Indépendance Belge, on the Liberal side; and, on the Catholic side, the Belfort, as the organ of the clerical party, with the Etoile Belge, are the leaders of public opinion.

Holland.—The newspapers of Holland were at an early date remarkable for the fullness and accuracy of their intelligence; but until 1830 their number was small, about six being published. The principal Dutch journals of to-day are the Algemeene Handelblad of Amsterdam, and the Amsterdam Courant; the Haarlemsche Courant; and the Journal de la Haye, De Nederlandersche
far into the 19th century. There are now fifty daily papers published in Italy, chiefly in Rome, Bologna, Florence, Genoa, Milan, Leghorn, Naples, Palermo, and Turin. The Secolo of Milan is credited with a daily circulation of 120,000.

Peter the Great was the author of Russian journalism. Originally, it was, as ever, practically forbidden in the dominion of the czar, the papers occupying themselves for the most part with literary and scientific questions. The Journal de St Petersburg (1824) is semi-official, and, though it has but a small circulation, it is well known throughout Europe, being duplicated in French. The two daily papers of largest circulation are the Novoe Vremia ("New Times"), the organ of the popular party, and the Novosti ("Latest News"), which represents the doctrinaire Liberals.

Journalism in Turkey is chiefly of foreign origin, and the French were the first to exploit this form of enterprise in the land of the sultan. Any opposition to the government is not permitted, therefore the Turkish papers contain no leading articles. Some fourteen sheets, however, are issued daily in Constantinople, in Turkish, French, and English. The latter is the Djedide Heddé, was established in 1843 by an Englishman.

The papers of Austria have similarly expanded and improved in recent years. Vienna is a very active centre, and within its boundaries many excellent papers are issued, the Neue Freie Presse and the Neue Wiener Tagblatt being the most important.

Newstead Abbey, 10 miles NNW. of Nottingham, on the border of Sherwood Forest, was founded for Augustinian Canons by Henry II. in atonement for Becket's murder (1170), and in 1540, after the dissolution was given to "Sir John Byron the Little, with the great beard." Among his descendants were the first Lord Byron (c.1613), the "wicked Lord Byron" (1722-98), and the poet Lord Byron (q.v.), who made the half-ruinous old place his home in 1808, and which he repaired, for which time about £100,000 has been spent on its restoration. For a full description of Newstead, its lake, ruined church, superstitions, and memories, see Washington Irving's Abbotsford and Newstead (1833).

New Style. See Calendar, Chronology.

New Sweden. See Pennsylvania.

Newt, or EPT (Triton), a genus of caduce-branched Amphibians (see AMPHIBIA), somewhat resembling the Salamanders, but more slender and active, and making up with them the family Salamandridae. The newts have a soft, sensitive skin, covered with warty tubercles or granules; a laterally compressed tail; four fingers and five toes; teeth on the jaws and palate above and below; a lower eyelid, and a third eyelid or nictitating membrane; small nostrils near the snout, opening internally into the mouth; and generally well-developed organs of the lateral line. They are found in marshes and ponds and damp places. In habits they are carnivorous, devouring insects of various kinds, worms, snails, frog-spawn, and even smaller animals of their own kind. Sixteen species are enumerated, widely distributed in Europe, and found also in Algeria, North China and Japan, the Eastern United States, California and Oregon. The Great Water Newt, or Warty Newt (T. cristatus), is the largest British species. It is about 6 inches long; the body is thick and round, the upper parts are generally very dark, the sides are dotted with white, and the breast and belly are of a bright orange colour,
with black spots. The male is more vividly coloured than the female, the sides of the tail are of a beautiful pearly colour, and at the breeding season he develops a large back crest (fig. 1). The movements

Fig. 1.—Great Water Newt (Triton cristatus).
in slow swimming are accomplished by means of the tail and the limbs; but in fast swimming both pairs of limbs are laid alongside the body, and the movements are effected by rapid undulations of the body and tail. On land they crawl by means of their weak limbs. In summer they cast their skin perhaps many times, sometimes by complete sloughing, but sometimes it comes off in shreds. In winter they generally remain at the bottom of ponds and ditches. Like many other animals of the same genus, they show great power of reproducing lost parts, the tail, limbs, and portions of the head being very perfectly restored, even several times in succession. They are also able to withstand great cold. In laying her eggs the female deposits them on the leaves of aquatic plants, each egg being deposited separately below a leaf, which is then folded, apex to petiole, by means of the newt's hind-limbs, so as to retain the egg in position. The embryo grows rapidly and becomes bent in shape. In seven days the gills and legs appear as small knobs. By the ninth day the tail is ear-shaped, and the heart may be seen beating. On the tenth day the fore-limbs and claspers appear beside the gills. In two or three days more the eyes appear as distinct structures, and the gills become leaf-like. About the fourteenth day the embryo escapes from the egg and holds on to leaves of water-plants by means of its claspers. At this stage of its existence it resembles a fish in outward form and internal structure, and its whole anatomy may very easily be studied on account of its transparency. About twelve days after leaving the egg the fore-feet are longer, rudiments of toes are visible; the gills, at first simple, become fringe-like, and red blood circulates through them, and the claspers disappear. About the twenty-second day it begins to breathe by means of its developing lungs; the gills are still large, and the hind-legs begin to sprout. This change takes place concurrently with the change of diet from vegetable to animal food. About the forty-second day after hatching, the gills begin to grow smaller and are soon obliterated. The newt then seeks to leave the water, requires atmosphere and warmth, and grows on to sexual maturity. In some circumstances individuals of this species occasionally retain some of the external appearances of immaturity in spite of having become capable of reproduction (a phenomenon more common, however, in a European species, T. alpestris, which becomes sexually mature even in its tadpole stage); and in rare instances they may bring forth their young alive as do the true salamanders. The Great Water Newt is seldom found on land. The Common Smooth Newt (T. palmtipes), a smaller species about 3 inches long, is much more common in Britain than the great newt, from which it also differs in having a smooth skin, the back crest continuous with the tail crest, and in being often found on land. Its eggs are laid in the axils of leaves quite as often as under the leaves. The Palmated Smooth Newt (T. palmtipes) is the only other common British species. It has been found in various parts of Britain from the Isle of Wight to the north of Scotland. The toes of the hind-foot are webbed, the tail ends in a long filament, and the back crest is straight; these characteristics are prominent and the newt is the breed of the diagram.

Newts form very interesting inmates of aquaria, where they may be easily reared and kept; and their graceful movements and development interest the observer. The words newt and newf are really identical, a newf or an cewf, A.S. ecfa, just as an adder resulted from a naldher by mistake.

Newton. (1) capital of Harvey county, Kansas, 134 miles by rail from Topeka, is the centre of a rich coalfield. Pop. (1901) 6289. (2) a city of Massachusetts, 7 miles WSW. of Boston by rail, and almost surrounded by the Charles River. It contains many suburban residences belonging to citizens of Boston, and has manufactures of cloth, silk, shoddy, machinery, glass, &c. Pop. (1900) 8382; (1890) 24,379; (1880) 33,587.

Newton. Sir ISAAC, the greatest of natural philosophers, was born on 25th December (o.s.) 1642—year remarkable in English history for the breaking out of the Civil War, and doubly remarkable in the history of science by the birth of Newton and the death of Galileo. The farm-house he was born in, still preserved religiously at the hamlet of Woolsthorpe in Cottersworth parish, Lincolnshire, 8 miles S. of Grantham (q.v.), at whose grammar-school the boy received his early education. On the 5th of June 1661 he left home for Cambridge, where he was admitted as subazar at Trinity College. On the 8th of July following he matriculated as sizar of the same college. He immediately applied himself to the mathematical studies of the place, and within a very few years must have not only made himself master of most of the works of any value on such subjects then existing, but had also begun to make some progress in the methods for extending the science. In 1665, in which year he took his B.A., he committed to writing his first discovery on fluxions; and in 1666, according to Voltaire's Lettres sur les Anglois (1733), the fall of an apple, as he walked in the garden at Woolsthorpe, suggested the most magnificent of his subsequent discoveries—the law of universal gravitation. On his first attempt, however, by means of the law so suggested to his mind, to explain the lunar and planetary motions, he employed an estimate then in use, the radius of the earth which was so erroneous as to produce a discrepancy between the real force of gravity and that required by theory to explain the motions, corresponding to the respective figures 161 and 18-3.
He accordingly abandoned the hypothesis for other studies. These other pursuits to which he thus betook himself consisted chiefly of investigations into the nature of light and reflectors of telescopes. By a variety of ingenious and interesting experiments upon sunlight refracted through a prism in a darkened apartment, he was led to the conclusion that rays of light which differ in colour differ also in refrangibility. This discovery enabled him to find an imperfect image of the telescope which had not till then been accounted for. The indistinctness of the image formed by the object-glass was not necessarily due to any imperfection of its form, but to the fact of the different coloured rays of light being brought to a focus at different distances. He concluded rightly that it was impossible for an object-glass consisting of a single lens to produce a distinct image. He went further, and too hastily concluding, from a single experiment, that the dispersive power of different substances was proportional to their refractive power, he pronounced it impossible to produce a perfect image by a combination of lenses. This conclusion—since proved erroneous by the discovery of the achromatic telescope (see ACHROMATISM)—turned Newton's attention to the construction of reflecting telescopes; and the form devised by him is the one which is still in use. He wrote, at Kensington, the hands of Sir William Herschel and Lord Rosse.

Newton became a Fellow of Trinity in 1667, and Lucasian Professor of Mathematics in 1669; and it was on 11th January 1671 that he was elected a member of the Royal Society, having become one of the secretaries of the society from his reflection of telescopes. At what period he resumed his calculations on gravitation, employing the more correct measure of the earth obtained by Picard in 1670, does not clearly appear; but it was in the year 1684 that it became known to Halley that he was in possession of the whole theory and its demonstration. It was on the urgent solicitation of Halley that he was induced to commit to a systematic treatise these principles and their demonstrations. The principal results of his discoveries were set down in a treatise called De Motu Corporum Externarum, which was afterwards completed, and unfolded in the great work entitled Philosophiae Naturalis Principia Mathematica, which was finally published about midsummer 1687.

Shortly before the Principia was given to the public he was elected a fellow of the Old Bursars, and took an active part in defending the rights of the university against the illegal encroachments of James II. The conspicuous part which he had taken on that occasion procured him a seat in the Convention Parliament, in which he sat from January 1680 to its dissolution in 1683. In 1696 he was appointed Warden of the Mint, and was afterwards promoted to the office of Master of the Mint in 1699, an office which he held till the end of his life. He again took a seat in parliament in the year 1701 as the representative of his university. Thus engaged in his public service, he had little leisure for his scientific studies—pursuits which he always held of secondary importance to the public duties in which he was engaged. In the interval of public duty, however, Newton showed that he still retained the scientific power by which his great discoveries had been made; for he had shown solutions for the celebrated problems proposed in June 1696 by John Bernoulli, as a challenge to the mathematicians of Europe. A similar mathematical feat is recorded of him so late as 1716, in solving a problem proposed by Leibnitz for the purpose, as he expressed it, of the public interests: the hypothesis of comets.

When in parliament Newton recommended the public encouragement of the invention of a method for determining the longitude—the first reward in consequence being gained by John Harrison for his chronometer. He was president of the Royal Society from 1703 till his death, a period of twenty-four years, and in this position he could do much for the advancement of science; and one of his most important works during this time was the superintendence of the publication of Flamsteed's Greenwich Observations—a task, however, not accomplished without difficulty, for the resistance was so great between himself and that astronomer. The controversy between Newton and Leibnitz as to priority of discovery of the differential calculus, or the method of fluxions, was raised rather through the partisanship of jealous friends than through the anxiety of the philosophers themselves. But they were, however, induced to enter into and carry on the dispute with some degree of bitterness and mutual recrimination. The verdict of the impartial historian of science must be that the methods were invented quite independently, and that, although Newton was the first inventor, a greater debt is owing by later analysts to Leibnitz, on account of the superior facility and completeness of his method. In 1699 Newton was elected a foreign associate of the Academy of Sciences, and in 1703 he received the honour of knighthood from Queen Anne. He died at Woolsthorpe on 20th March, 1727, and his remains received a resting-place in Westminster Abbey, where a monument was erected to his memory in 1731. Roubilliac's magnificent full-length statue was erected in 1756 in the antechapel of Trinity College, Cambridge.

Besides the first and second editions of the Principia, other editions appeared in 1713, 1726, 1729, 1730; and at Geneva the Jesuit's edition (1730–42; republished at Glasgow, 1822). An admirable reprint is that by Lord Kelvin and Professor Clerk-Maxwell (Glasgow, 1875). An English translation of the Optics appeared in 1706; the Optical Lectures in 1728; the Fluxions in 1736; and Horsley edited an edition of his collected works (5 vols. 4to 1779–83). Newton was a student of Alchemy (q.v.); and he left a remarkable monument of his interest in theology, especially prophecy, a MS. work on the prophecies of Daniel and on the Apocalypse, a history of the Cretaceous and a number of tracts. See also on this work Astronomy, Fluxions, Gravitation, Light, Motion (Laws of), Optics, Spectrum; Sir David Brewster's Life of Newton (1855); and Augustus de Morgan's Life of Sir Isaac Newton (1885); his Friend, a Life of Sir Isaac Newton (1868), and his Fantasia, a Life of Sir Isaac Newton (1879). Newton's successor as master of the mint, who in 1717 married Newton's niece, Katherine Barton, the widow probably of the Earl of Halifax.

NEWTON'S RINGS.—In his investigations of the colours produced by thin plates of any material, solid, fluid, or gaseous, Sir Isaac Newton hit upon the following mode of exhibiting the colours produced by reflection from a film of air. He took two lenses, one convexo-plane, its convex side having a radius of 14 feet, the other equi-convex, with the radii of its surfaces 50 feet, and laid the first with its plane surface downwards on the top of the second, so as to fit closely between the lenses; the film being thinnest near the centre, and becoming gradually thicker outward. On slowly pressing the upper lens against the under one, a number of concentric coloured rings, having the point of contact of the two lenses for their centre, began to show themselves in size when the pressure was increased. These rings, or more properly systems of rings, are in this form of the experiment seen in number, and each of them is composed of a number (ranging from eight in the first or smallest ring to two in the outermost) of rings of unequal sizes, the colours, though different in each of the systems of rings, preserving the same arrangement as the colours of the spectrum; thus, in the second ring the inside
Newton, John, the friend of Cowper, was born in London, 24th July (n.s.) 1725. He had little schooling, and, as his father was master of a trading ship, he was trained at eleven and sailed under him for six years. Next impressed on board a man-of-war, he was made midshipman, but was degraded and cruelly treated for an attempt to escape. He was allowed at Madeira to exchange into an African trader, joined a slaver at Sierra Leone, and sailed with her for two years, returning to England in 1747. He next sailed to Guinea and the West Indies as mate on a Liverpool slaver, married in 1750, and made several voyages of the same nature as master, giving his leisure to study. In 1762 he removed to becoming to become tide-surveyor at Liverpool. His religious views had already undergone an important change, which led him to apply in 1758 to the Archbishop of York for holy orders, but without success. In 1764 he was offered the curacy of Olney, and he was at once ordained deacon, and next year priest, by the Bishop of Lincoln. Hitler the poet Cowper came about four years later, and an extraordinary friendship quickly sprang up between the two men. Newton was a burning Calvinist, and it cannot be doubted that the converted slaver’s influence was to a great extent disadvantageous to the sensibility of the poet. Newton left Olney in 1779 to become rector of St Mary Woolnoth, London, and there he died, December 31, 1801. Newton’s prose works, Omicron (1762), Caradiphos (1781), &c., are now but little read, save his vigorous and interesting Authentic Narrative of Two Interesting and Remarkable Particulars in his own Life. But his name can never be forgotten from its association with Cowper, and from some of his Olney Hymns, which have been taken to the heart by the English-speaking religious world. Of these need only be named here: ‘Approach, my soul, the mercy-seat;’ ‘How sweet the name of Jesus sounds;’ ‘One there is above all others;’ and ‘Quiet, Lord, my froward heart.’

See the Life by Richard Cecil (1898), prefixed to a collected edition of Newton’s works (6 vols. 1816); Thomas Wright, The Town of Cowper (1886); and other works cited at Cowper.

Newton, Thomas, was born at Lichfield, January 1, 1704. From Westminster he passed to Trinity College, Cambridge, became one of its fellows, took orders, and after minor preferments was made Bishop of Bristol and Canon of St Paul’s in 1761. He died 14th February 1782. Newton’s annotated edition of Milton’s Paradise Lost and Paradise Regained, and his Dissertations on the Prophecies (3 vols. 1754-58) long enjoyed a reputation.

Newton-Abbott, a market-town of Devonshire, at the influx of the Lumen to the Teign estuary, 15 miles (by road 20) S. of Exeter. Ford House, a good Tudor building, has lodged both Charles I. and William of Orange, who here in 1688 was first proclaimed king. Pop. (1851) 3147; (1891) 10,951.

Newton Heath, a town and local government district, and parliamentary borough of Manchester, with a pop. of 29,180.

Newton-in-Makerfield (otherwise Newton-le-Wills), with its suburb of Earlton, a thriving town of Lancashire, 16 miles E. of Liver-
as usages of New-year’s Day. Suetonius alludes to the bringing of presents to the capital, and Tacitus makes a similar reference to the practice of giving and receiving New-year’s gifts. This custom was continued by the Christian kingdoms into the Middle Ages, and in the twelfth century this custom has been largely eclipsed by the still more popular practice of Christmas gifts (see CHRISTMAS); in Scotland, as in France and Italy, New-year’s Day is still the day most observed, and the festival according to Old Style, twelve days later, still lingers in corners of the country. In some parts of the United States and Canada gentlemen are exceptionally industrious in making social calls on the first day of the year. In many countries the night of New-year’s Eve, “St Sylvester’s Eve,” was celebrated with great festivity, which was prolonged till the following day, and New-year’s Day was ushered in with congratulations, complimentary visits, and mutual wishes for a happy New Year; this is an ancient Scottish custom (see HOGMANAY). In many places the practice of tolling bells till midnight, and then “ringing in the New Year,” is observed, and in some places the mummings are wont to celebrate it with a special service or “watch night.” In the Roman Catholic Church New-year’s Day is a holiday of strict obligation. See Chamber’s Book of Days.

New York, called the “empire state,” is the twenty-first ormunited, the first in population, and the fifth in pop., per. of the United States. It lies be-
tween 45° and 40° 39’ N. lat., and between 71° 5’ and 79° 47’ W. long. It is triangular in shape, and has an irregular outline. Its boundary line measures 4129 miles, of which 879 miles, or nearly two-thirds of the entire length, lie along the shores of Lake Erie, the Niagara River, Lake Ontario, the St. Lawrence River, and Lake Champlain. The remaining portions of the boundary are formed by arbitrary straight lines. Altogether about one-third of England, Long Island is the largest, and Manhattan, containing the most populous part of New York City, is the most important of the many islands.

The surface structure of New York is remarkably diversified, and presents many contrasts of elevation. The state is traversed by numerous chains of mountains and hills, among which lie beautiful valleys. There is also much rolling land, and there are several extensive plains. The greatest elevations are in the eastern and north-eastern parts of the state, but nearly the whole of the south-eastern part is low. From this highland region the land slopes gradually, and declines in a series of terraces, north and west toward Lake Ontario. The most level portions are those bordering that lake and the St. Lawrence River. The mountainous region in the east is cut by the gap of the Mohawk River. The narrow valley of this stream, once traversed by a mighty river which drained the great Ontario basin, joins at right angles the deep depression in which are Lake Champlain, Lake George, and the Hudson River. Both of these valleys pass directly through the Appalachian mountain system. South of the Mohawk valley are the Catskills with various associated groups, such as the Helderberg and the Shawangunk Mountains, covering an area of about 500 sq. m. The Shawangunk Mountains are continuous with the Blue Ridge system of the United States. The escarpment of the Taconic range of New England enters the state still farther south, and passes south-westward into New Jersey. This range is cut by the Hudson River, and forms the celebrated Highlands.

The geology of New York is peculiarly interesting and comprehensive. With the exception of the Jurassic formations and a few others closely related in time with the Jura-Trias, its rocks exhibit deposits of nearly every period, from the primitive Archean rocks to the Tertiary and recent alluvium. Briefly and superficially classified, the outcropping rocks are disposed as follows: In the north-eastern part of the state, with the Adironducks as a centre, is a somewhat circular area of Archean formation. Along the eastern side of the Hudson River and near its mouth, the Archean rocks again appear, and are continued with the primitive formations of New York. The Adironducks are a belt of Silurian rocks, which extends southward along the western shore of the Hudson, and westward, bordering upon Lake Ontario and Lake Erie. North of the Adironducks is a belt of Carboniferous rocks, and south and west of this belt are the Silurian rocks. The Silurian rocks of the state, with traces of Carboniferous deposits, but no true coal-measures. There are in the state some extensive iron-mines, deposits of lead, copper, zinc, and other valuable minerals, and an abundance of building stones. The hot-springs, especially those of the Onondaga salt group, are of great value. There are also valuable petroleum springs, and mineral and medicinal springs—the most noted are those at Saratoga, Ballston, Sharon, Richfield, Avon, and New London.

The most important river belonging entirely to the state is the Hudson (q.v.). The Oswego, draining a chain of lakes in the central part of the state, the Black, and the Genesee are affluent of Lake Ontario; the St. Lawrence forms part of the boundary with the province of Quebec; the lakes of Lakes Erie and Ontario, and the Delaware, the Susquehanna, and the Allegany rise within and drain the southern portions of the state.

New York lies mainly in the lake region of North America. The eastern part of Lake Erie, Lake Ontario, and Lake Champlain are controlled by the state. Among the numerous lakes of north-eastern New York, Lake George and the Adironducks are the most noted. There are three groups of picturesque lakes in central New York. The mountains, rivers, and lakes of New York make it famous for its scenery. Of this, one of the most noted features is the number of waterfalls, among which the mighty Niagara is of course pre-eminent. Other beautiful falls are the Falls of the Genesee (q.v.), Trenton Falls, the Kaaterskill Falls in the Catskills, and those of Cohoes, Ticonderoga, and at Watkins Glen.

The average temperature of New York is about 47° F., with a range of over 100°. The climate is thus subject to extremes, but is very healthful. Although the surface is so diversified, most of the soil is arable, and much of it is fertile. More than one-half the state lies under the plow, and the production of corn and wheat is the highest in the United States. The usual farm products are raised in abundance. In the lake valleys there are many vineyards. Hops and tobacco are also important crops. In the vicinity of New York and the other large cities market-gardening is a profitable occupation, and the highland regions yield excellent milk, butter, and cheese. But manufacturing is the leading
industrial, and in the value of its manufactured products New York is the foremost state of the Union. Moreover, its geographical position and its natural avenues of communication with other parts of the country, together with the system of canals and railroads, make it the leading commercial state. There are several canals, of which the Erie (see Canals) is the most important. New York is the centre towards which nearly all the great railroads of the country tend, and within the state there are over 8,100 miles of railway.

Previous to the coming of the whites the territory now known as New York was occupied by the Iroquois (q.v.) Indians. Almost simultaneously, in 1609, Samuel Champlain discovered the lake which bears his name, and Henry Hudson explored the Hudson River as far as the present site of Albany. A few years later settlements were made by the Dutch, but they were looked upon as intruders by the English, who in 1664 forced them to surrender their city of New Amsterdam, which had grown up on Manhattan Island. The name was then changed to New York, and, with the exception of a short period in 1673, the city remained in the possession of the English till the war for the supremacy in which, as in the war of 1812, and the civil war, the state played a prominent part. The physical structure of the state has made it a most important factor in the development of the nation, and in population, wealth, and political influence it has always held a pre-eminent position.

The school-system is among the most complete in the country. The University of the State of New York, through its regents (elected by joint ballot of the legislature), exercises supervision over educational institutions in the state, and grants charters to universities, colleges, academies, libraries, and museums. The university has in its membership 688 teaching institutions, including universities, colleges, professional and technical schools, and incorporated academies, with a total of 81,471 students, male and female, and 6,440 instructors. The system includes over 11,000 school districts, with an average daily attendance of 820,254, not quite one-half the estimated school population.

Politically the state is divided into sixty counties; it returns the largest number (37) of members to congress. No other state of the Union has so many large cities and thriving, enterprising towns. New York City is the centre of a thickly populated district, which is second only to London in the number of its people and the importance of its commercial interests. The other most important cities are Albany (the capital), Buffalo, Rochester, Troy, Syracuse, Utica, Oswego, Kingston, Elmira, Poughkeepsie, Auburn, Cohoes, Newburgh, Yonkers, Binghamton, Schenectady, Lockport, Rome, Ogdensburg, Watertown, Hudson, and Dunkirk. Pop. of the state (1890) 5,899,051; (1895) 5,997,394; (1896) 5,997,833; (1900) 7,268,894.

New York City, or officially (since May 4, 1887) The City of New York, is the largest and most important city on the American continent, and the third wealthiest on the globe. It is situated on New York Bay at the confluence of the Hudson and East Rivers, about twelve miles from the Atlantic Ocean, and embraces since 1897 in its amplified area the former cities of New York, Brooklyn, and Long Island City, and the suburban sections appertaining thereto. The City of New York, as at present constituted (1898), is divided into five boroughs, designated respectively Manhattan, Bronx, Kings, Richmond, and Queens counties, lying immediately north of the city of New York.

The borough of Manhattan, containing the most important districts of the city, is situated on the island of Manhattan, and stretches from the upper part of the Hudson River to the lower part of the East River, and from the shore of the east to that of the west. It is divided into four sections: Lower Manhattan, including the financial district; Central Manhattan, including the main business district; Upper Manhattan, containing the residential districts; and the island of Staten Island. Manhattan Island is 134 miles long, with an average breadth of 13 miles, and with the exception of a small portion of wild and stony space, which is being utilised for ornamental purposes, the entire island is laid out in avenues and streets. It includes several greens and parks, and its area has been considerably extended by filling in on the river sides.

The bar at Sandy Hook, 18 miles south of the city, which divides the Atlantic Ocean from the inner bay, is crossed by two ship-channels, from 21 to 32 feet deep at ebb-tide. The lower bay covers 88 sq. m. for anchorage. In it are buildings for quarantine and hospital purposes, and an anchored floating hospital-ship, in charge of a health-officer. The Narrows, through which all the ships pass on their way to the inner harbour, is a strait between Long Island and Staten Island, about a mile in width, 8 miles distant from the city, in a south-easterly direction. This approach is defended by forts Wadsworth, Tompkins, and Hamilton. There is also another channel leading
Night and day sumptuous passenger steamers pass up and down Hudon River, Long Island Sound, and beyond the New berows, down to the lower bay. Lines of railroads rate from the Grand Central Depot; others run from the opposite shorees of New Jersey and Brooklyn. The large city depot is 695 feet long and 240 wide; about 125 trains arrive and dep. Desi of the city's avenues are traversed their full length by elevated steam passenger-railroads, build on wrought-iron structures, which from early dawn to midnight carry crowds of local passengers. Besides these there are many lines of horse and cable train-rail roads, and a considerable number of omnibus agencies. ready these modes of conveyance are so saturated that additional travelling facilities are urgently demanded. More river-bridges, a viaduct avenue, subterranean roadways, and tunnelling under the rivers are in active contemplation; for most of these enterprises charters have already been granted. The number of houses is estimated at above 120,000, mostly built of red brick, the better class of brown sandstone, a few of wood. Besides these there are stores built of iron, brown and yellow sandstone, and a few of marble; little granite and a great variety of modern structures. The construction of wooden buildings in the lower part of the city has been interdicted. The modern tendency is to build roomy, tall, fireproof and semi-fireproof structures for apartment-houses and for business purposes, the internal ascents of which are made, from story to story, by mechanical elevators. Most of these structures range from 75 to 100 feet in height, and are costly and elegant. Among prominent public edifices are noteworthy: the City Hall, County Court-house, Custom-house, Treasury Building, City Prison, Barge Office, and Masonic Temple; Madison Square Garden Hall, University of the City of New York, Lenox Library, Temple Emanuel, Trinity Church, and the Roman Catholic cathedral, besides numerous large, imposing hotels and palatial dwellings and business depots. In many cases vaulted basements and sub-cellars are laid out under the buildings and sidewalks on an extensive scale. Among the apartment-houses conspicuous for size and luxurious appointments are Navarro's Spanish Flats, the Dakota, Gerlich, Knickerbocker, and Tompkins Buildings, besides several others. The way side streets the dependent and poorer classes are huddled together in equally tall, brickbuilt, dirty, yardless tenement houses. Immense retail bazaars and arcades are found on Broadway, Grand Street, 14th, 25th, and 125th Streets, and 3d, 6th, and 8th Avenues. The government of The City of New York is (1898) vested in a mayor, who is the chief executive, and two legislative bodies termed respectively a council and a board of aldermen, the two together styled "The Municipal Assembly of the City of New York." The police force numbers 3420 men; there are thirty-five station-houses for prisoners and for the homeless. New York has a paid firedepartment, conducted at an annual expense of $2,000,000, and divided into 70 companies; 1099 fireengines, 78 steam, 15, trucks, and 84 telegraph stations. The lighting of the city is mostly done with gas, although electric lighting is gradually being brought into use. Of public gas-lamps there are some 25,000, and a number of private companies have together about 900 miles of mains laid under ground. The Croton Aqueduct conveys to the city an ample supply of soft water from the Croton River and its lakes, a distance of about 40 miles, to the four reservoirs of the city (see AQUEDUCT).
In Central Park the retaining reservoir holds 1,030,000,000 gallons, the receiving reservoir 150,000,000 gallons, the distributing reservoir on 5th Avenue 20,000,000 gallons; at High Bridge there is a receiving reservoir with a regulated capacity of 11,000,000 gallons. The iron main-pipes are little short of 500 miles in length. Electric telegraphs and telephones are largely in use. The New York General Post-office building, erected of granite, at a cost of $6,650,000, was first occupied in 1838. It is situated on the site of the old Washing- ton Hall, a structure erected from 1789 to 1791. The New York Public Library, the main section of which is in Washington Square, occupies the site of the old City Hall Park, in the lower part of the city. More than 2500 persons are here employed. There are 18 stations and 20 sub-stations in various parts of the city, and 1690 lamp-post boxes. A federal commissioner now receives and attends to the wants of immigrants. In some years the immigration by way of New York has risen to nearly half a million.

The Battery Green encloses twenty-one acres, planted with trees, shrubbery, and grass, and occupies the most southern point of Manhattan Island; it marks the original site of Nieu Amster-
dam. After the American revolution it was used for military and civic displays, and from that time until near the middle of the 19th century was the fashionable promenade. On its west side is Castle Garden (q.v.). The grading of Central Park was begun under the direction of Frederick Law Olmsted in 1855, the design of which is said to have been formed in his mind during a visit of about 2 months to the Zoological Gardens at Alexandria. It was formerly known as the City Hall Park, in the lower part of the city. More than 2500 persons are here employed. There are 18 stations and 20 substations in various parts of the city, and 1690 lamp-post boxes. A federal commissioner now receives and attends to the wants of immigrants. In some years the immigration by way of New York has risen to nearly half a million.

New York has 97 local fire-insurance companies, 10 local marine-insurance companies, 39 local life-insurance companies, 83 commercial banks (of which several have a capital of $5,000,000), 23 savings banks, and 18 trust-companies. About 258 newspapers (daily, weekly, and monthly) are published—some of them in foreign languages; the prominent journals occupy immense buildings. Dispensaries, hospitals, and charitable institutions are numerous. Homes for the aged and crippled, the insane, idiotic, blind, deaf and dumb, magdalens, and foundlings are provided. Of church buildings there are about 400—91 Episcopal, 88 Methodist, 84 Presbyterian, 59 Roman Catholic, 54 Baptist, and 29 Jewish. There are congregations of Christian Scientists, Quakers, Armies, Spiritualists, and Chinese. Of the public schools 47 are primary and 85 grammar-schools, each jointly under a male and female principal. Many children of Roman Catholic parents are being withheld from these institutions, in favor of parish schools of their own. In 1899-1900, the daily attendance at day schools averaged 307,000; at evening schools about 20,000. There are four general colleges—Columbia, the University of the City of New York, the College of the City of New York, and the Normal College, the last two being denominational organizations. Besides these there are many special colleges and academies, Union Theological Seminary (Presbyterian), the Protestant Episcopal General Theological Seminary, &c. Among libraries may be named the Astor, with 900,000 volumes; Mercantile, 250,000; Columbia College, 120,000; Apprentices', 100,000; Historical Society, 100,000; and Society, 70,000. The Museum of Art, Museum of Natural History, and Academy of Design are entirely supported by public contributions. Annual exhibitions of paintings and satirical cartoons are held at the Academy of Design and other places, and of mechanical inventions at the hall of the American Institute. The theatres are numerous and well appointed. Noted clubs are the Manhattan, Union, Commercial, St Nicholas, and Union League, University, Lotus, Harmonie, and Century. The principal orchestral society is the Philharmonic.

John Verrazani, a Florentine navigator, was the first European who entered New York bay, in 1525. His expedition was interrupted by a storm that compelled him to put to sea without making a settlement. In 1609 Henry Hudson entered Hudson River, and, trading with the aborigines, ascended the stream for about a hundred miles. In 1614 the Dutch built a fort on Manhattan Island, and in 1626 a permanent settlement was made, named Nieu Amsterdam. In 1664 the English drove out the Dutch, in 1673 the Dutch the English. In 1674 Manhattan Island came permanently by treaty into the possession of Great Britain, the name New York being given in honour of James, Duke of York. This name is maintained. The site of the fort was used by the British as a gunpowder magazine during the great business during the climax of the slave importation, about 1780-35. At the time of the American Revolution the city's population was less than that of Philadelphia and Boston. It was evacuated by the forces of Great Britain in 1783, and from 1783 to 1798 was the seat of government for the United States. In 1774 the city census, taken by government, showed a population of 22,861; (1800) 60,489; (1825) 106,130; (1830) 50,534; (1839) 813,669; (1870) 942,292; (1890) 1,206,399; (1899) 1,615,391; and (1900) 1,710,715. In 1898 Brooklyn, Richmond County, Flushing, Port Hempstead, Jamaica, Long Island City, Newton, Jamaica Bay, East and West Chester, and Pelham were incorporated with the municipality; and 'Greater New York,' with an area of 339 sq. m., according to the census of 1900, has a population of 3,437,307.

See Histories by Lossing (1855) and Roosevelt (1891); the article TAMMANY, the Memorial History, edited by Grant Wilson (4 vols. 1891-94); and Historic New York, by Misses Goodwin, Royce, and Putnam (1898).

New Zealand. New Zealand lies in the South Pacific Ocean, comprises three main islands—named the North Island, the South or Middle Island, and Stewart Island, the last being much the smallest—besides a number of islets near the coast. The North and South Islands are long and narrow, so that no place is more than 75 miles from the coast. Their position relative to Australia is much the same as that of Turkey to England, as they lie 1200 miles more to the east and stretch 600 miles farther south. The main islands have a length of 1100 miles, and lie between 34° 22' and 47° 18' S. lat. and 166° 27' and 172° 34' E. long. Projected out into the sea, beyond the limits of the southern continent, these latitudes would begin in central France and end in the north of Africa. The total area of the colony is 106,240 sq. m., or about one-eighth less than that of Great Britain and Ireland. Cook Strait, a deep and somewhat stormy passage of about 12 miles, is the only narrow water that separates the North and South Islands. Foveaux Strait, about 15 miles in width, divides the South Island from Stewart Island.

Coast Features. In its northern half the North Island is bounded by a long sandy coast, and contains many excellent harbours; the southern half has but one harbour, that of Wellington or Port Nicholson in the south-west corner. The coast of the South
Island is little broken except in the north-east and south-west corners, where the country is mountainous; but the volcanic projections of Banks and the main chains are frequently irrigated by rivers, which have been greatly improved by moles and dredging. The ports carrying on the great import and export trade of the colony are Auckland, Napier, and Wellington in the North Island, and Lyttelton, Dunedin (Port Chalmers), and Bluff Harbour in the South Island. Coasting steamers call at numerous minor ports, the chief being, in the North Island, the Bay of Islands, Tauranga, Gisborne, Foxton, Wanganui, New Plymouth, Manukau, and Kaipara; and in the South Island, Nelson, Petion, Akaroa, Timaru, Oamaru, Hokitika, and Invercargill. The coast-line is probably one of the most picturesque in the world; for the inhabited parts of the South Island are low land clothed with impenetrable forest, save where miners and farming settlers have made clearings, and where the broad river-beds come down to the sea. A coach-road passes over the main chain at a height of 3900 feet, connecting the country of Canterbury, the most mountainous, and a railway was in course of construction along the same picturesque but difficult route. In the North Island much of the finest land is covered by forests of tropical luxuriance, which ascend the mountains to a height of 4000 feet, but the greater part of the South Island is very scantily supplied with timber, and mountains and lowlands alike are open and well grassed, yielding good pasture even in their natural condition. The great peninsula north of Manukau Harbour differs from the rest of New Zealand in enjoying a humid semi-tropical climate. Much of this region is covered by a luxuriant vegetation, and the land is likely to be rich, and the crops of the warmer latitudes grow in great abundance and perfection. Settlements can here live like the peasantry of Spain and Italy, growing flowers for perfumes, manze, figs, olives, grapes, oranges, lemons, mulberries, and other tender fruits. This district is the home of the noble kauri pine, and supplies most of the kauri gum brought to the market. The numerous inlets and the large Waioa River give ready access to the best of the land.

Climate.—The climate of New Zealand is one of the best and healthiest in the world. The rate of mortality has been decreasing for a number of years, and is now as low as 934 per thousand. Diseases from malaria are unknown. Owing to the great length of the islands the climate presents considerable variety, and the direction of the mountain-chains determines its effect on the land alone. The average temperature is remarkably equable at all seasons, and the air is singularly fresh, being constantly agitated by winds that blow over a boundless expanse of ocean. The climate is such as Italy would have if it were 1000 miles from the nearest land, and much more like that of London, where the weather is generally more changeable, but there are fewer wet days. The country is everywhere well watered, and prolonged droughts are unknown. Snow seldom falls even in the southern lowlands, and it usually melts in a day. The mildness of the winter allows cattle and horses to remain in the fields without shelter, and even in the south dairy cows are housed at night only for a few months. The prevailing winds blow from the south-west and are often chilly and boisterous. Other winds are light, with line westerly; but the gales are much the heaviest in the Southern Alps. Strait and along the eastern edge of the plateau-like offshoots of the Southern Alps.

Scenery.—For variety, picturesqueness, and wild grandeur, the scenery of New Zealand is unrivalled in the southern hemisphere. The scenery of the central part of the island rapidly becoming Australia and the far East what Switzerland is to Europe. In the North Island is the wonderland of the volcanic belt,
remarkable for its hot lakes and pools, which possess great curative virtue for all rheumatic and skin diseases, its boiling geysers, steaming fumaroles, sulphur-basins, and punice plains. These and other wonders, once the region of Mount Ruapehu, were exposed to the active volcano of White Island in the Bay of Plenty. The exquisite siliceous terraces of Rotomahana, once the cauldron of the eণousure of the island, are now buried beneath the debris of Mount Tarawera, almost shattered by the eruption of June 1886. This region shows better perhaps than any other quarter of the globe the sudden and expiring efforts of a prolonged cycle of volcanic activity, and every part of it can be explored without hardship and in perfect security. A well-appointed sanatorium is carried on at Rotoma by the government for the healing of the people of the Australasian colonies, and is much frequented. Earth tremors and slight earthquakes are not uncommon in the neighbourhood of Cook Strait, but they have done less harm since the colony was settled than earthquakes have done in England during the same period. In the South Island the Central Alps of the Mount Cook district display to the visitor the grandest glaciers in the temperate zones, splendid clusters of snowy mountain-peaks, and stormy precipices of solid ice. Fifteen miles off to the east of the island, the westernmost of the splendid yellow-tinted lakes. Farther south the Otago lakes—Wanaka, Wakatipu, Te Anau, and Manapouri, embosomed in mountains 5000 to 8000 feet high—present some of the finest lake and mountain scenery in the world, and prove an unfailing source of delight, in whatever season of the year. The under creed of the west coast of Otago is pierced by a series of deep and tranquil sounds of exquisite beauty, charming the beholder now with their picturesque variety, and anon with their precipitous grandeur and impressive quietness and gloom. Milford Sound, near which are the famous Sutherland Falls, 1904 feet in height, is justly reckoned one of the finest sights the world has to show.

Flora and Fauna.—New Zealand is a group of true oceanic islands, having been severed from all adjoining lands for countless ages. Originally it contained a number of species of birds and animals. The next highest animals were a few small and harmless lizards, the largest being the remarkable 'tataua,' famous for its median pineal eye hidden under the skin of the head. Among the birds are several of peculiar beauty. The Pukeko (see Pukeko) has recently acquired the habit of killing sheep by pecking the flesh of the loins, and several wingless kiwis (see Ateryx), the punci surviving relatives of the gigantic Moas (q.v.), now extinct, but in former times the lords of creation in these islands. The Maoris brought dogs with them, and doubtless the native rat also. Cook gave them pigs, whose wild descendents are still common enough in spots remote from settlement. The colonists introduced the common domesticated animals of Europe, which all thrive to surprising advantage. Many kinds of English bees, and also black swans from Australia have been established in the country, and they are now numerous, and in some cases very troublesome. Most unfortunately rabbits also have been neaificially introduced. Their swain in such numbers as to be a serious pest, and reached a population of 15,000,000 in 1865, and £100,000 a year to keep in check. Fresh-water fishes of many kinds have been introduced with great success, but salmon have proved hard to establish. The honey andumble bees multiply to an extraordinary degree. In fact, acclimatisation experiments have proved only too successful, and the colony would gladly pay a million or more to be rid of rabbits, sparrows, and linnets altogether. Nearly all the native trees and shrubs are evergreen. The most important plants are the timbers. The best pine is the kauri, but rimu, matai, and totara are also of great economic value. Many other native trees are of merchantable size, tawa, bush, kowhai, &c.—yield excellent timber. The Phar- mina or native flax thrives best in wet ground, and grows wild in great profusion. The smaller native grasses yield excellent pasture, and the tall 'toit-oi' and Danthonia surpass the well-known grasses in elegance of form. Ferns, punga, kiwi, and kinds greatly abound, including numerous tree-ferns. The fruit and other trees of temperate zones thrive admirably, and a great variety has been already introduced. European grasses and cereals spread with great rapidity, and so do weeds of every kind, especially sweetbread, gorse, thistles, cat's ear, sorrel, and docks. Most of these plants grow with a luxuriance unknown in England. Many garden flowers have also run wild.

Soil and Productions.—The deeper alluvial soils and the extensive tracts of limestone formation are both extremely fertile. Considerable tracts of the Canterlury and the inland plains are shallow and arid, and require irrigation, which is now extensively applied. The rest of the lowlands is clayey and heavier to work, but yields a good return for tillage or under pasture. The best lands of the North Island are the 8,137,804 acres of land on the sown pastures alone. On good land wheat yields a return of 60 to 70 bushels an acre, and oats do still better. The average yield of cereals per acre is: wheat, 25 bushels; oats, 32 bushels; and barley, 27 bushels; while potatoes give 54 tons; and potatoes and grass together give £3,976,374 to the people in the form of food. The annual cost of wheat being £489,728 and oats £236,086. Including flour, meal, bran, &c., the whole export of grain produce was £2,248,866. This produce went chiefly to Australia, wheat alone going in quantity to London. Frozen, preserved, and salted meats were valued at £292,221, the frozen meat alone reaching £753,374. Nearly a million frozen sheep were shipped to England, and it is believed that the pastures will in a few years yield twice as large a supply. Notwithstanding this enormous drain on the flocks of the colony, they become every year larger and more valuable. The annual figures of the exports, the entire home consumption of the articles exported being of course provided for in addition. Wool amounted to £3,576,73, the produce of 164 million sheep. The home consumption was 3,556,004 tons. There were nearly 4,414,199 acres of land in pastures, and 33 million acres of land were sown with grass without ploughing, chiefly in the fern and forest lands of the North Island. The people are a farming people, and their chief employment is the raising of agricultural and pastoral produce. The volume of these productions may be judged from the following:—The aggregate of the exports, the entire home consumption of the articles exported being of course provided for in addition. Wool amounted to £3,576,73, the produce of 164 million sheep. The home consumption was 3,556,004 tons. There were nearly 4,414,199 acres of land in pastures, and 33 million acres of land were sown with grass without ploughing, chiefly in the fern and forest lands of the North Island. The people are a farming people, and their chief employment is the raising of agricultural and pastoral produce. The volume of these productions may be judged from the following:

Fuels and Lumber.—The most important of the forests are the beech, pine, and kahikatea, which abound on the coast, while the interior is rich in the silver fir, pampas and ash woods, and the mountain beeches. Logs valued at £3,156,233, are now being cut, and will afford a supply for many years. The output of fir and pine will exceed a million feet a year, besides ash, beech, and kahikatea, and the export, to America, of timber and timber products, is now valued at £209,590. The chief product is timber, but many valuable timbers are also obtained, among which are the pukatea, kahikatea, manuka, totara, and kauri. The pukatea and kahikatea are mostly exported raw, the manuka sometimes in the form of chair-legs, the totara in the form of posts and beams, &c., and the kauri in great quantities for shipbuilding and for the manufacture of grass. The kauri log was valued at £3,156,233, and now fetches £276,393; timber, £199,293; tallow, £159,460; potatoes, £93,996; leather, £65,487; seeds, £45,233; bacon and hams, £83,156;
hope, £13,965; onions, £12,063; oysters, £8,745; fungus (for the Chinese market), £15,903.

Minerals.—The chief mineral product is gold, much of which is obtained by alluvial mining. The total export up to 1889 was 11,625,928 oz. for that year 203,211 oz. For years this export has been declining in value, but recent developments of alluvial mining promise a considerable permanent increase. Silver, lead, copper, antimony, and other minerals are produced in small quantities, and by crude processes. The coal raised in 1889 was 568,445 tons. The import of this mineral is less than a fifth of the home production, and comes chiefly as return cargo from New South Wales. There are extensive fields of Greywacke and Westport is unsurpassed in quality for gas and steam purposes. Brown coal and lignite are mined in most parts of the colony, and afford supplies of cheap fuel. The other mineral resources are little developed, but the recent success in culminating the iron sand which abounds on the west coast of the North Island seems to prove the dawn of a great and permanent iron-working industry. The number of miners is about 25,000, or 4 per cent. of the population.

Manufactures.—The manufactures are entirely of domestic consumption in the colony. They are stimulated by high protective duties, are rapidly growing, and afford employment to a large part of the population. The chief are woollen cloths, wools, hosiery, blankets, soap, candles, leather, biscuits and confectionery, boots and shoes, paper, machinery, implements, apparel, ropes and twine, beer, &c.

Trade.—The volume of foreign trade increases every year, and for several years the exports have exceeded the imports. The excess of exports over imports grew from £308,654 in 1887 to £9,942,108 in 1889. This implies that the colony is rapidly paying off its debts. In 1894 the total exports were £9,231,047, the total imports, £6,788,020. In 1889 the total exports were £9,330,205, and the total imports £6,397,697. Of the exports there were sent to Britain £6,653,982, to Australia £2,145,671, and to the United States £314,362. Of imports, £4,126,311 came from Britain, £1,107,132 from Australia, and £342,436 from America.

Finance, &c.—The consolidated revenue was £4,209,247, and the expenditure £4,121,842. The chief items are customs duties (average 25 per cent. ad valorem), stamps, post-office, telegraph and railway profits, property-tax, and pastoral rents. The net public debt (March 1890) was £57,234,918, bearing an annual charge of £1,851,421. There were 1912 miles of railway, which cost nearly £15,000,000, and yielded a profit of £412,782, nearly 3 per cent. on the capital invested. The railways have proved an excellent investment. They and the telegraph lines belong to the state, though there are two private railways of considerable importance. The telegraph lines measure 11,827 miles, and are the longest service provided in the larger towns. Three submarine cables connect the North and South Islands, and two the colony and New South Wales, thus bringing New Zealand into telegraphic communication with the world. The property tax, property is valued at £220,000,000. In 1890, with the increased value, the tax had a value of £7,137,320, and the exports of £9,321,105, the total revenue was £4,107,108 and the expenditure £4,370,481. In 1897 the revenue was £4,708,708 and the expenditure £4,509,981. In the same year the net debt (allowing for a sinking fund of £14,924) was £43,592,324.

Education.—Only some 9000 or 10,000 persons above ten years of age are unable to read and write. Elementary education is free, compulsory, and secular. A highly efficient education is given at the 1155 public schools, which are attended by 115,456 scholars, and maintained at a cost of £394,000 a year. There are also 72 schools for the natives (Maoris) alone, costing £20,600 a year. Higher schools for boys and girls are numerous, and many of them have valuable endowments. These are attended by 2147 pupils, and cost £43,900 a year. There are three university colleges at Auckland, Christchurch, and Dunedin respectively, each attended by 588 students. There is a college connected to the University of New Zealand, established by royal charter. It is only an examining body, and has granted 236 degrees in arts, science, medicine, law, and mining.

School Education.—More than 19 million acres have been already alienated by the crown. There were (December 1889) 37,342 freeholders of areas of 5 acres or more, of whom 35,548 held 1000 acres or less. About 400,000 acres have been taken up for settlement annually for some years. Rural lands may be acquired cheaply, and on most liberal terms. Selectors are restricted to 460 acres of first-class, and to 2000 acres of second-class land. Land is sold for cash mostly at auction, or taken on deferred payment (the price being paid in equal instalments spread over 14 years), or on perpetual lease. The price of the land is based on its capital value, by paying which the freehold can be secured at any time. The last is the most popular form of tenure. In 1889 the average price of cash lands was 18s. 6d. an acre, the average yearly installment on deferred payment lands 6s., and the average rent on perpetual lease lands 10s.

Population.—In 1851 the white population was 26,767; (1861) 99,022; (1871) 236,260; (1881) 489,933; (1890) 578,482. In 1891 the pop. was 262,638, exclusive of 42,000 Maoris. More than half the people have been born in the colony, and about 15,000 are of non-British descent. Nowhere out of England does so pure an Anglo-Saxon community exist. There are 4500 Chinese residents. Five-sixths of the people are Protestants. Anglicans predominate in Canterbury and Prebendaries in Otago, and there are Methodists in Waikato, Taupō, &c., and there are numerous Roman Catholics, and a large number of Presbyterians. 115,000 are Pakehas, or British-born people of New Zealand stock. A large number of the people of English extraction, who have come over from the mother-country, are distinguished by an exclusive feeling, and have a strong desire for independence. They take their own national parks, or acquire land for new settlements in New Zealand. They are mainly a middle-class stock, of the same variety as the English of the United States, but russer in muscular frames, with legs that are short for their stature. The head is well shaped, and, though the lips are generally thick, the features are not unpleasing, and are often handsome. The skin is
usually an olive-brown. Most of them have long black, slightly waved hair, but in some it is reddish. Tattooing, once practised by both sexes, is now almost abandoned. The punctures were made with a knife and small, polished chisel, and were stained with the soot from kauri wood. The patterns, which extended over the face, hips, thighs, &c., consisted of ornamental spirals and serpents, elaborated according to the wearer's rank. The women were but slightly adorned in this fashion. The few remaining tattooed, and could at will make any person or object 'tapa' or Taboo (q.v.) - i.e. sacred and inviolable. This was partly a religious and partly a political institution, and it was always respected by mutually hostile tribes, even in times of war. Cannibalism was universally prevalent as part of their system of warfare. The last known instance of it occurred in 1843. Infanticide, commonly practised in their heathen days, is now everywhere abolished, as is the case with slavery and polygamy. They marry early, but have few children, three to a family on the average. Many die in infancy and childhood. At the time of Cook's visit, and down to the formation of the colony, the tribes lived in a chronic state of warfare. They fought with clubs and spears of heavy wood and stone, and made excellent fortifications. Their most remarkable weapon was a short club, one end of which was wrought into a hook. Among the chiefs these weapons descended from father to son, and were regarded as precious heirlooms. Other nephrite weapons were highly valued and very costly. Firearms are now in common use among them, but in the olden time they had no knowledge of pottery and metal, and few tools, bow and arrow. Their alphabet contains only fourteen letters, and every word and syllable ends in a vowel. Their names of places, rivers, &c., have generally passed into current use among the colonists. The language is rich and sonorous, and well adapted for the oratory, songs, and lyric poetry of which they were passionately fond. Five-sixths of their numbers are nominally Christians. Those living within or on the border of settlement are becoming gradually assimilated to it, as Europeans, &c., in remote parts they are even now content with a blanket for a garb. They still own large areas of land, on which they raise crops and keep great numbers of sheep, but they are not very industrious. They will wish to have their children educated, and send them regularly to school. They have a special franchise, and elect four members to the House of Representatives; two of their chiefs are members of the Legislative Council. In Cook's time they numbered 100,000, but there are now no more than 42,000, who almost all live in the North Island. The 'King movement' has grown in length and boldness, and the haughty and sullen 'King tribes' are giving up the seclusion into which they retired after the last native war.

History.—Tasman discovered the islands in 1642 and named them New Holland. Van Diemen made them known to the world. He surveyed the coasts and learned a great deal about the people in 1679 and following years. At the beginning of the 19th century whaling-ships began to frequent the coasts and to have intercourse with the natives, and the trade of the native flax sprang up with the young settlement at Sydney Cove. This trade was stimulated by the eager desire of the Maoris for guns, tools, and utensils of iron, and blankets. The introduction of guns made the constant tribal wars more deadly than ever, and brought still greater numbers into the number of the people. The continual fighting and disorder caused the British government to include the islands in the territory of New South Wales, and soon led to the cession of the colony to the British crown by the treaty of Waitangi (1840). By this treaty the native title to the soil was guaranteed, and every acre since sold has been legally paid for. Missionaries were sent to them in the north in 1814, and soon formed a network of stations over the North Island. Within twenty years their labours were crowned with remarkable success, not only in converting the people, but equally in encouraging a more peaceful and civilised mode of life. The colony was planted in 1840 by the New Zealand Company, who with auxiliary associations founded successively the settlements of Wellington, Nelson, Taranaki, Otago, and Canterbury. The earliest and most irregular settlement was at the Bay of Islands. For a time the capital was fixed at Auckland, but in 1865 it was transferred to Wellington. A series of native wars began in 1843 and ended in 1860, since which year the colony has enjoyed complete peace. The wars arose partly from jealousy of the power and influence of the colonists, but chiefly from endless disputes about land. This was set forth and interdicted by the vague tribal tenure on which land was held by the natives. All through the wars, which were brought to an end by the united colonists, the trade and population of the colony grew at a rapid rate. Self-government was granted in 1852. In 1853 the constitution of the colony was altered by the enactment of the Native Land and Protection of Native Land Act, which limited the power of the legislature. The Constitution Act were abolished in 1875, and the government centralised and strengthened, while a complete system of local government by county and borough councils was soon after established. The government consists of a governor appointed by the crown, and a legislature composed of the upper chamber named the Legislative Council, with members appointed for life, and a lower chamber named the House of Representatives, elected for three years.

NEY, MICHÈL, French marshal, was born at Saarlonis, 10th January 1769. He was a non-commissioned officer in a hussar regiment when the Revolution began, but in the new order of things his merit quickly brought him promotion, and during the revolution of 1792-93, Ney made him his adjutant-general. In 1796 he served under Jourdan, and earned the rank of general of brigade on the field of Foretarme. For the capture of Mannheim by a daring coup de main he was made a general of division in 1799. He was in the war against Russia, in which the great victorious army of Napoleon was formed, and achieved the distinguished part of Gneisenau in the battle of Austerlitz. For this short time, during which he was sustained by a bold diversion an important movement of the Archduke Charles against Massena and the Army of Switzerland. After the peace of Lunéville Bonaparte brought about his marriage to Angélique de Lestrade, a young friend of Hortense Beaufillarmais, and appointed him inspector-general of cavalry. On the establishment of the empire he was made marshal of France. In 1805 he stormed
the entrenchments of Ebleingen, for which he was created Duke of Ebleingen. He distinguished himself anew at Jena and Eylau, and his conduct at Friedland earned him the title from Napoleon of ‘le brave des braves,’ and the grand-egale of the Legion of Honour. He next served in Spain, but quarrelled with his superior Massena about the plan of the campaign and returned to France, where he remained inactive till 1812 he received the command of the third corps in the Grand Army. He covered himself with glory at Smolensk and Borodino (q.v.), and was rewarded with the title of Prince of the Moskva. He led the rear-guard in the disastrous retreat, and his sleepless vigilance alone saved the remnant of the Grand Army.

In 1813 he opened the battle of Lützen, and showed his usual capacity and courage at Bautzen, but was defeated by Jellöw at Dannewitz. He fought heroically throughout the fatal struggle at Leipzig, and was also in the last defensive campaign of 1814; but after the capture of Paris he urged the emperor to abdicate, and submitted to Louis XVIII., who loaded him with favours. On Napoleon's return from Elba Ney was sent against him at the head of 4000 men; but the old enthusiasm proved too much for him, and with most of his soldiers he went over to his old master’s side. In the final campaign he commanded the first and second corps, opposed Brunswick at Quatrebras (June 16), and led the centre with more than bravery at Waterloo twice—once at the head of the cavalry, last with the Old Guard—he strove to break the English force in vain. During the day he had five horses shot under him. After the capitulation of Paris he yielded to the entreaties of his family to set out for Switzerland; but a costly Egyptian salar, the gift of Napoleon, led to his being suspected by an official, and arrested near Aviarc. He was condemned to death for high treason, and was shot in the garden of the Luxembourg on 7th December 1815—a cruel act of revenge that might well have been spared the bravest among the sons of France. Even the cost of the prosecution, 26,000 francs, was extorted from his unhappy widow. He left three sons, who published his Mémoires (2 vols. 1833).

Nez Péreès, a tribe of American Indians, settled in Idaho, on the Lapwai River. The Nez Péreès ‘proper’ have always been loyal to the whites, and are making good progress in civilization. But in 1877 the treaty reductions of their reservation led to a sanguinary outbreak on the part of the ‘non-treaty’ Nez Péreès, who murdered settlers, fought the soldiers, and then fled across Idaho, Montana, and Dakota. They were over-taken and beaten, and the survivors (some 320) transferred to Indian Territory; but in 1885 some were restored to Idaho, and the rest joined the Colville Indians, in Washington. There is no evidence that they ever had a custom which would justify their name, ‘pierced nose.’

Namii, Lake, a South African lake, situated at the northern extremity of the Kalahari Desert, in 20°30’ S. lat. and 23° E. long., at an altitude of 2810 feet. Its extent and depth vary with the fall of rain in the country to the north of it; its average size is 50 miles long and from 10 to 20 broad. The chief tributary, the Okavango or Cubango, called in its lower course the Tjioeg, brings down from the north-west vast volumes of water. At another season of the year the Siga or Zonga brings in a supply from the east. It is not yet decisively settled whether in times of flood the lake sends off the surplus water to the Zambesi.

Niagara (‘Thunder of Waters’), a river of North America, which forms part of the boundary between New York state and the province of Ontario. It flows from Lake Erie to Lake Ontario, a course of 36 miles, during which it makes a total descent of 326 feet—about 50 feet in the rapids immediately above the great falls, and nearly 110 feet in the seven miles of rapids below. It encloses several islands, the largest Grand Island, which is nearly 10 miles long. Four miles below this island are the most famous falls in the world. The centre of the river here is occupied by Goat Island, dividing the cataract into two—the Horseshoe (Canadian) Fall, with a descent of 188 feet, and the American fall, 162 to 169 feet; the outline of the former is about 2640 feet, of the latter 1000 feet. The volume of water which sweeps over this immense chasm (nearly nine-tenths passing over the Canadian fall) is about 15,000,000 cubic feet a minute. The depth of water on the crest of the falls is less than 4 feet, except in a few places, notably at the apex of the Horseshoe Fall, where it is about 20 feet. The limestone edge of both falls is rapidly wearing
away in the centre; the contour lines in the map represent this in the case of the Canadian fall, whose crown now presents the form of a V; in the American fall the same tendency is visible, although the fall is lower. There are rocks six miles below the falls (to the point, that is, where it has been supposed that the falls originally stood) the river is shut in between perpendicular walls of rock, from 200 to 350 feet high. For some distance below the falls there is still water, the body of water which pours over the precipices sink- ing, and only coming to the surface again two miles below, where the whirlpool rapidly begins; a little lower is the whirlpool, where a sharp turn sends the waters hurtling against the Canadian side, and then sweeping round in a great eddy before they find a vent at right angle with their former course. Just below the cataract the river is crossed by a suspension bridge for carriages and foot-passengers, and a mile and a half farther down there are two railway bridges—one a cantilever bridge—about 100 yards apart. On both shores the lands bordering on the river, for some distance above and below the falls, are under the immediate control of the respective governments. The 'New York State Park at Niagara Falls' (1885) embraces 115 acres, and the 'Queen Victoria Niagara Falls Park' (1885). From the terraces visitors, covered in waterproofs, are conducted under the falls. On October 4, 1890, the first sod was cut of a tunnel for utilising the water-power of the falls, regarded as one of the greatest engineering enterprises ever undertaken. By means of immense turbines, the water-power generates electricity, which is distributed to commercial enterprises in the immediate neighbourhood or transmitted to considerable distances. By the middle of 1893 the first transmission of electric power for commercial purposes had been made, 4000 horse-power having been transmitted to an ammunition factory a mile distant. The city of Buffalo, twenty-six miles away, is well within the sphere of the company's operations; in November 1886 the electric energy of the three great turbines at Niagara was made available here, and henceforward the tramways as well as the great agencies of the company were worked by this power. It is expected that ere long the whole distance between Buffalo and the Falls will be 'built solid with smokeless factories.' It has even been proposed to use the electric forces generated for the canal-boats on the canal hence to the Hudson River at Albany, 200 miles distant.

Niagara, a town of Ontario, popular as a summer-resort, is situated on Lake Ontario, at the mouth of the river Niagara, 15 miles from the falls. Niagara (then Newark) was burned down in 1813 by the Americans in retreat. Pop. 1441.—Niagara Falls, a village of New York, is the principal place in the neighbourhood of the falls. The name Niagara Falls has also been given to Clifton (q.v.).

Niam-niam, an African people dwelling along the watershed that parts the feeders of the Bahr al-Ghazal from those of the Welle-Makua and other northern tributaries of the Congo. Of the negroid Nuna stock, they have round faces, broad heads, bodies long in proportion to the legs, and are inclined to corpulency. They have no cattle. Considerable manual and artistic skill is shown in the forging of iron, making of pottery and baskets, and the carving of wood. They are passionately fond of food and drink, of money and of seeking some kind ofertainment. It is not strange that these people that the legends of 'tailed men' are referable (see Baring-Gould, Curious Myths, 1875). See also Schewinfurth, Heart of Africa (1878); and Junker, Travels in Africa, vol. ii. (1891).

Nias, an important island belonging to Holland, lies to the west of Sumatra, and has an area of about 2100 sq. m. The surface is mountainsous, the highest peak rising 1970 feet. In 1857, when the Dutch took complete possession of the island, the population was reckoned at 170,000. They grew rice, coconuts, bananas, tobacco, and cardamons, &c., and annually about 110,000 lb. of pepper. The Niasse are of the Malay race, but fairer than the Malys usually are. They are gentle, sober, and peaceful, remarkably ingenious in handicraft. See Roy. Scot. Geog. Mag. for 1888 and 1891; and Medlicott, Malay, 1890.

Nibelungenlied, also called Der Nibelungen Nört, an old German epic poem, which takes rank next after the Homeric poems amongst the great epics of the world. The original substratum of the work is undoubtedly the saga of Sigurd, recounted in the Elder Edda; it is from that source the epic derives its mythological elements, and in all probability the tragic conception of an all-compelling destiny which dominates the action of the poem. To this original substratum must be added two others—one taken from the legendary history that grew up out of the migrations of the peoples, especially the struggle between the Huns and the Burgundians; the other embodying the spirit, the sentiment, the life and circumstances of the crowning age of chivalry, the middle of the 12th to the middle of the 13th century, during which period the poem, arrayed in its present unchangeable form, was written. Who was its author, or rather the man who cast it in its present form, is altogether unknown; the attribution of it to the minnesinger of Kirengen in Upper Austria now finds very little acceptance. The oldest elements of the work have been preserved in the form of popular songs or versified sagas; but the incidents of the story as recounted in the epic seem to have been fused into a unity some time previous to the 12th century. The existing version is due to one writer as stated in the ideas of the courtly poetry of the middle ages; the writer took the story that had in process of time grown together into a connected epic narrative, and impressed upon it his own methods of poetic vision, and his own peculiar versification—in short, his own style. Gerhard, the German poet who translated the mighty work, worked from originals composed in Latin. After the Reformation all interest in the poem quite died out, and was only revived in the end of the 18th century. But it was not until twenty years and more of the 19th century had passed that German students began to be aware of the inestimable literary treasure they possessed in the Nibelungenlied. A keen discussion arose as to its unity; one school, headed by Lachelmann, maintained that it was merely a collection of folk-songs, loosely strung together, or rather intermixed one with another; an opposing school defended the unity of the narrative and of the poem. The views of the latter body of scholars are now generally accepted.

The narrative is briefty this. Sigfried, the son of the king of the Netherlands, has become the possessor of two storied Nibelungs, which carries with it the curse of dire evil to its owner. Sigfried marries Kriemhild, sister of Gunther, king of Worms, and then helps Gunther to win to wife Brunhild of Ieland, by taking Gunther's treasure without her knowledge. On coming her in three trials of bodily skill and strength. After some years a bitter dispute breaks out between the heavens as to whether Gunther or Sigfried is the greater. Brunhild's jealousy is so great that she induces Hagen, one of Gunther's vassals, to kill Sigfried. When Sigfried's body is burned, she mourns long years for her husband, at length marries Etzel (Attila), king of the Huns. After Sigfried's death she had become the possessor of the
Nicolaves' treasure; but Hagen had wrested it from her and sunk it at the bottom of the Rhine. At the end of several years Kriemhild, who still mourns for Sigfried, and still nourishes the desire for revenge upon Hagen and Gunther, invites her brothers to an assembly at the Hall of Kriemhild, accompanied by a body of 11,000 knights and men-at-arms. The conclusion of the epic relates the bloody incidents attendant upon the total annihilation of the Hunsgradians at the court of Etzel, and the slaughter they made amongst their foes. There is another day of doom called to witness by Nicolave. genklonge, or Lumen for the Nicolaves, a production in every way much inferior to the Nicolave- genklage, or Lument for the Nicolaves, a production. In spite of the uncouth versification of this last, it exercises a strong fascination upon the reader, owing to the grandeur of its conception, its strong characterisation, its earnestness and tragic intensity.

There exist numerous old MSS. of the poem; but the most valuable are three, called respectively the Munich, St Gall, and Lassberg MSS., all of the 13th century. The best modern version is the lyrical translation of the English poet, Robert Browning, 40th ed. (1880). Bartsch (2d ed. 1880). 1st Freytag (2d ed. 1886). There are English translations by Lutsen (1880), Foster-Birham (1887), and Birch (3d ed. 1887). See also Carlyle's Miscellaneous (vol. iii.).

Nicaea. See Nice.

Nicaragua, an independent state of Central America, situated between the isthmus from the Caribbean Sea to the Pacific, between Costa Rica on the south and Honduras on the north. An irregular square, the coast (Caribbean) coast measuring 290 miles and the west coast 185, Nicaragua has an estimated area of about 49,500 sq. miles. An Aztec country, it is the backbone of the country; they run north-west and south-east at a distance of 12 to 30 miles from the Pacific, and attain elevations of 4000 and 5000 feet above sea-level. On the west the surface sinks rapidly to a longitudinal depression (110 feet), the southern two-thirds of which are filled by the large lakes of Nicaragua (115 miles long, 45 broad, and 140 feet deep in most parts) and Managua (35 miles long, 20 broad, 30 feet deep), the latter lying north of the former and 25 feet higher. This depression is studded with a chain of volcanic cones, standing on islands in the lakes (Ometepec and Maderon, 4190 feet), and clustering thickly between the northern end of Lake Managua and the Gulf of Fonseca at the north-western extremity of the country, as Cosguena (3335 feet), which was the scene of its tremendous outbreak, lasting over four years, in 1853. Viejo (2067), Telica (4200), Monimotombo (5690), Momhachito (4600), and several others. Though most of these are quiescent, some of them burst forth in eruption from time to time; Ometepec poured out its lavas during seven days in 1853. Another low range separates this depression from the Pacific. The districts west of the central backbone are the chief seats of the population. There stand the towns Managua (the capital), Leon, Granada, Chinandega, Iliivas. On the western coast there are three larger and his court to visit her. In the north, Salinas Bay in the south, and the port of Corinto towards the north. The only port on the east side is Greytown, at the mouth of the river San Juan.

East of the Cordilleras the surface falls away gradually; the spurs that break off from the main ridge are the alluvial plains that lie in the Caribbean Sea. Thick forest cloths extensive areas on this side. Several rivers carry off the surplus water eastward, a few being of good length, such as the Coco or Wanks (350 miles long), which serves as the conventional northern boundary; the San Juan (155 miles), which drains Lake Nicaragua and separates the state of Nicaragua from Costa Rica on the south; the Bluefields and the Rio Grande (230 miles). The low coast-belt, called the Mosquito Coast (q.v.), is lined with salt lagoons—Pearl lagoon having an area of about 200 sq. m., and Bluefields lagoon half as much. The mountains are rich in minerals; gold is mined in the province of Libertad on to Matagalpa, in the heart of the country, and silver near the sources of the Coco in the north; coal, copper, tin, iron, lead, zine, antimony, quicksilver, marble, &c. exist, but are not worked. As a rule the rainy season lasts from July to September, and there is a dry season lasting from about December to May. The natural products of the soil are accordingly tropical. The forest trees include mahogany, rosewood, logwood, fustic, sandalwood, India-rubber, and numerous others that yield fancy woods, medicinal plants, gums, and dye-woods. Large herds of cattle are bred and reared on the extensive plains of the centres and east. The rich soil of the cultivated western region yields maize (the staple food of the people), coffee, cocoa, sugar, cotton, rice, tobacco, indigo, and a great variety of tropical fruits. The exports—chiefly coffee, India-rubber, bananas, limes, metals, gums, woods—average $2,400,000; the imports, mostly manufactured goods, $2,800,000. The animal life is similar to that of Guatemala (q.v.).

The population in 1893 was 220,000—about 1500 persons of European extraction, the others negroes. The state religion is the Roman Catholic, but all creeds are tolerated. The educational standard is low, in spite of two universities (so-called); at Leon and Granada, with about 350 students in all. The country is governed by a president (elected for four years), a legislative assembly of eleven members, and a senate of ten; both of these bodies are elected by the people, the former for three, the latter for six years. There are 100 miles of railway, connecting the chief towns with Corinto. The public revenue (about $3,840,000) is derived chiefly from imports on spirits, tobacco, and gunpowder, and from import duties. The national debt amounts to $2,000,000.

Nicaragua, like the states north of it, was a centre of Aztec civilization; but the Aztecs were preceded by another race, likewise civilized, who have left to the country some monuments of the most ancient remains. The Aztec influence survives in archeological ruins and relics and in the Indian dialects. Columbus sailed along the Mosquito coast in 1502. Twenty years later the country was overrun by the Spaniards under De Fonseca and D'Avila, and in 1524 the city of Granada was founded. This town soon developed as the head of a stream of commerce that flowed up and down the San Juan River. In 1610 was founded Leon, the democratic rival of the aristocratic Granada. During the Spanish supremacy (after 1550) Nicaragua was a province of Guatemala. In 1821 it asserted its independence, and two years later joined the federation of the Central American states, a connection that lasted sixteen years. The history of the country after the severance from Spain until 1853 is a record of war and revolution. The war was with Costa Rica, 1850 to 1856, and with Guatemala, and with Great Britain (1848), which had asserted a protectorate over the Mosquito Coast since 1855. This region was given up to Nicaragua in 1860. Between 1855 and 1860 the aristocratic and the democratic party were fighting throughout the country, with the rule assisted by the adventurer William Walker (q.v.). Since then Nicaragua has made laudable efforts to develop her resources and to advance along the path of civilisation, and she now compares most favourably with her sister states in Central America.

See Squier, Nicaragua (1852); Del, Naturalillas in Nicaragua (1873); Bodham-Whetham, Across Central.
Nicaragua Ship-canal. The plan of cutting
a canal through Central America by way of
the San Juan River and Lake Nicaragua is by no
means new. But the project was not taken up in
earnest until 1884, when a treaty was signed, this object
in view, between the United States and
Nicaragua. The Nicaragua Canal Company was
formed early in 1889, and operations were com-
menced at Greytown, at the mouth of the San
Juan, in November of the same year. During
the first year of work the harbour was cleared, a pier
built, and some 10 miles of railway constructed,
and the ground cleared for excavation. The plans
have been prepared by A. G. Menocal of the
United States navy. The canal utilises the San
Juan and Lake Nicaragua, and will have a total
length of 170 miles; of this distance 121 miles will
be free navigation on the river (64½ miles) and
lake (56½ miles), 21 miles free navigation on basins
formed by damming small streams, and 23 miles
only will be excavated. A breadth of only 12
miles, with a low divide (102 feet above sea-level),
inside the lake, is characteristic of the problem; the
river will be traversed from the lake exit near Rivas
to Port Brito by basin navigation and cut stretches
of artificial canal. There will be three locks on each
side of the lake (110 feet above sea-level), and
there will be a minimum depth of 30 feet of water
in the canal. The original estimated cost was
£12,000,000. A United States government com-
mission in 1895 thought £26,000,000 a more likely
figure, and recommended some modifications; and
financial and other difficulties have created serious
delays. See the problems discussed by Arch.
Colquhoun in The Nicaragua Company (1895).

Nicolai Pisano. See Pisano.

Niccolò da Foligno. See Alunno.

Nico, or Nica, a city of ancient Bithynia, in
Asia Minor, situated on the eastern shore of Lake
Aenus. It was built by Philip (316 B.C.), and received the name of Anti-
gona, which Lysimachus changed to Nicae,
in honour of his wife. It was a handsome town, and
of great importance in the time of the Roman and
Byzantine emperors. It is famous in ecclesiastical
history as the site of a synod of Patriarchs and
Seven Ecumenical Councils. The First Council
of Nica was held 325 A.D., and was convened by
the Emperor Constantine, for the purpose of defini-
ting the questions raised in the Arian controversy
(see ARES, ATAXASIAS); the Nicene Creed
adopted is discussed at Ch. 21. The Council also
deliberated on the Meleotian Schism; and its decree
on the celebration of Easter met with universal
acceptance. See Stanley's History of the Eastern
Church.—The Second Council assembled under the
Empress Irene (787), for the purpose of recon-
sidering the subject of Images (see IMAGE-WORSHIP).

Nicholas, the name of five popes and an anti-
pope. Nicholas I., born of a noble Roman
family, and was elected as successor to Benedict
III. in 858. He showed great persistence in his
endeavours to assert the supremacy of the Roman
curia, especially in his successful disputes with Arch-
bishop Johannes of Ravenna, Archbishop Illincen
of Rhiens, and with the Emperor Charles Augustus.
His latest triumph was the restoration to her rights of Thietberga, the unjustly divorced wife
of the Emperor Ludwig's younger brother, Lothaire,
knight of Lorraine. A synod of Metz in 862 had
allowed the king to put her away and marry his
mistress, but the pope reversed the judgment and
deposited the too compliant Archbishops of Cologne and Treves. Nicholas died in 868.—NICHOLAS V.
was originally called Thomas Parentucelli. Born at Pisa in 1395, he was educated at Florence and Bologna, and was named Bishop of Bologna by
Pius II. Pope Eugenius IV. summoned him during the
troubles of the Councils of Basel and Florence
that he was chosen to succeed Eugenius IV. in 1447.
He prevailed on the antipope, Felix V., to abdi-
cate, and thus restored the peace of the church in
1449. He was a liberal patron of sciences and
desperately agents both to the East and West, to
purchase or to copy important Greek and Latin
manuscripts. The number collected is said to have
exceeded 5,000. He remodelled, and may almost
be said to have founded, the Vatican Library. He
invited to Rome the most eminent scholars of the
world, and extended his especial patronage to
those Greeks whom the troubles of their native
country drove to seek a new home in the West.
He endeavoured to arouse the Christian princes of
Europe to the duty of succouring their brethren of
the East; but the age of enthusiasm was past, and
range in annual value from £94,656 to £56,982, the
greater part of which is being for olive-oil. It was re-
covering from £570,687 to £1,800,590, consist of
wine, oil, and cereals, with smaller quantities of
corn, charcoal, timber, bran, and flour. The ancient
Ligurian town of Nicaea, founded by a colony of
Phoenicians from Massalia (Marseilles), became sub-
ject to Rome in the 2d century B.C. It was in the
hands of the Saracens during the greater part of
the 10th century. Then, after existing as an
independent city, it acknowledged the supremacy of
the Counts of Provence and the House of Savoy
(1388). In 1548 it was taken and pillaged by the
Turks under Barbarossa. It was reconquered,
and was repeatedly taken by the French; and they
possessed it from 1792 to 1814. In 1860 it
was ceded to France by Sardinia (Savoy). Masséna
was born near to the city, and Garibaldi in it. See
Nash, Guide to Nice (1884).
he was forced to look on inactive at the fall of Constantinople in 1453. Nicholas died in 1455, at the comparatively early age of fifty-seven. He never considered himself as ruling under the eye of his mother, a princess of Wurttemberg, and subsequently devoted his attention to military studies and political economy. He visited England and other European countries in 1416, and in the same year made a tour through the Russian provinces. On 15 January 1417 he married the eldest daughter of Frederick-William III. of Prussia—a union that long affected European politics—and lived in domestic retirement till the death of Alexander 1. (December 1258), when, owing to the resignation of his elder brother Constantine, he succeeded to the throne of Russia. A long-prepared military conspiracy broke out immediately after his accession, which he suppressed with great vigour and cruelty. After a brief chicanery of reforming zeal, he reverted to the ancient policy of the czars—absolute despotism, supported by mere military power.

Soon after his accession a war with Persia commenced, but it was concluded by the peace of Turkmansh (1828), which gave a considerable extent of territory to Russia. In the same year he entered upon a war with Turkey, in which victory, though at enormous cost, constantly attended his arms, and the peace of Adrianople obtained for Russia another increase of territory. The political movements of 1830, in the west of Europe, were followed by a national rising of the Poles, which was suppressed after a desulting contest of nine months, in which the utmost efforts of the whole military resources of Russia were required. Nicholas punished the rebellion by converting the kingdom of Poland into a mere Russian province, and strove to extinguish the Polish nationality. This policy, however, was viewed with great dissatisfaction in Europe, and the Poles were everywhere regarded with general sympathy. Russia, by Nicholas's mode of government, became more and more separated from the fellowship of the western nations. Intellectual activity was, as far as possible, restrained to things national and domestic. The preparations for the public service, the press was placed under the strictest censorship, and every means used to bring the whole mind of the nation under official guidance. His Paussлавm (q.v.) also prompted him to Russianise all the inhabitants of the empire, and to convert Roman Catholics and Protestants to the Russian Greek Church, of which the czar is the head. War was waged against the mountains of the Caucasia with the greatest energy and perseverance, at the cost of immense sacrifices both of money and lives. The extension of British influence in central Asia was watched with alarm, and led to an unsuccessful expedition to Khiva. During the political storm of 1848-49 he abstained from interference until an opportunity was found in the request of the emperor of Austria for his assistance to quell the Hungmiarian insurrections. In 1854 he died, at the age of seventy, leaving closer the bonds of alliance between the Russian and Prussian monarchies. The re-establishment of the French empire still further tended to confirm these alliances, and led Nicholas to think that the time had at length come for carrying into effect the long-projected scheme of forming a league of protection for Turkey; but the unexpected opposition of Britain and France, and his own invincible repugnance to yield led to the Crimean War (q.v.). He died March 2, 1855. See Lacroix, Histoire de Nicolas I. (1864-73).—His great-grandson, Nicholas II., son of Alexander II., was born March 18, 1868, and succeeded his father in 1894. He married the Princess Alix of Hesse; and their coronation celebrations (marred by an accident that caused many deaths) took place in 1896. The chief event of his reign has been the entente with France.

Nicholas, a family of printers and antiquaries, associated with the Gentleman's Magazine from 1778 to 1828. The eldest son, John Nicholas (1745-1826); his son, John Bowyer Nicholas (1770-1863); and his son, John Gough Nicholas (1806-73).

Nicholson, John, a distinguished Indian soldier, was born at Lisburn, 11th December 1822. In 1838 he joined the East India Company's service, and in 1840 his regiment was ordered to Ghazni in Afghanistan (q.v., where, two years later, it was compelled to surrender to the enemy. After a time of miserable captivity he regained his liberty. On the breaking out of the Sikh war in 1845 he served in the campaign on the Sutlej, and was present at the battle of Ferozeshah. He was now appointed assistant to the resident at the conquered capital. During the Sikh rebellion of 1848 he greatly distinguished himself in the capture of the important fortress of Attock being due to his daring and promptitude, whilst soon after, at the Margalla Pass, he succeeded in intercepting and defeating a large body of the insurgents. At the battles of Chillianwalla and Gjrat successively he earned the respect, or rather the fear, of all whom he was immediately attached. The Punjab having finally become a British province, Captain Nicholson was appointed a deputy-commissioner under the Lahore Board. His success in bringing the savage natives of the under through the subjection to law and order was something marvellous.

In the mutiny in 1857 Nicholson perhaps did more than any other single man to hold firm the British grasp of the Punjab. He it was who suggested the formation of the famous movable column, and he presided over its organization. While in dealings with the suspected regiments of sepoys he exhibited throughout a brilliant combination of boldness with subtlety, discretion, and astuteness. At Tirimoo Ghat on the 12th and 14th July he nearly annihilated a force of rebels, and at Najatgarh on the 20th and 21st he defeated one of the mutineers. As brigadier-general, on September 14 he led the first column of attack at the siege of Delhi, and after the troops had forced their way into the city he still exposed himself in the most fearless manner, and fell, shot through the body. He died on 23d September 1857. Over the whole of India it was felt that, to use Lord Canning's expression, 'a tower of strength' had fallen.

See Kaye's Lives of Indian Officers (2 vols. 1867; new ed. 1889); R. Bosworth Smith's Life of Lord Lawrence; and Edwarde and Mervine, Life of Sir J. Lawrence.

Nicius, a famous Athenian statesman and general during the Peloponnesian war, was the son of Niceratus and by the name of Niceratus. He had acquired his fortune by working the silver-mines at Laurium. He belonged to the aristocratic party, and after the death of Pericles was the chief opponent of the demagogue Cleon, and later of the orator Isocrates. He had married Minna, next year he ravaged the island of Melos and the coasts of Locri, the next he compelled the Spartan force in Sphacteria to surrender, and defeated the Corinthians. In 424 he ravaged part of Laconia and captured the island of Cythera. After the death of Cleon he brought about a peace between the Spartans and Athenians, 421. Six years later the Athenians at the instigation of
Nickel (sym. Ni; atom. wt. 58.7; sp. gr. 8.90 to 8.94) is a metal discovered by Crousset in 1751; but long before he isolated the metal, alloys of it obtained from ore were used by the Chinese. Within living memory it was considered a feat to fuse a piece of nickel as large as a hazel-nut, so that it may be said to be a comparatively recent addition to the metals. It was shown by Richter in 1804, and again by Deville in 1856, that this pure metal is malleable and ductile and of higher tenacity than wrought-iron. Nevertheless the only application of nickel previous to 1879 was as a constituent of certain alloys—German silver (q.v.), patent copper, and cupronickel, giving them a white colour. In that year Fleitmann of Iserlohn, having previously ascertained that the brittle nature of all commercial nickel was due to occluded carboni oxide, discovered that the addition of one-eighth per cent. of magnesium (which requires a small quantity of nitrogen, an atmosphere of carbonic acid) conferred upon it the malleability of the pure metal. He was likewise successful in welding nickel thus refined to wrought-iron so thoroughly that two pieces of these metals—nickel and iron—joined in this way could be rolled out into a sheet without any break in the continuity of either surface. Fleitmann’s firm have turned this useful account by manufacturing cooking-pots and other articles iron-plated with nickel on both sides. The action of organic acids on nickel is so slight that these cooking utensils may be safely used. Nickel can also be made malleable by the addition of metallic manganese in the proportion of 5 parts of the latter to 100 parts of the former. This process was patented by Messrs Wiggins of Birmingham on 11th March, 1893, specification No. 1938. When manufactured in 1873 or earlier made vessels in America of pure nickel rendered malleable by forging it in a spongy state with a steam-hammer.

Nickel is of a white colour, its peculiar hue being between that of silver and bright steel. It is not altered by exposure even to moist air, and it is not tarnished by sulphuretted hydrogen. Dilute sulphuric and hydrochloric acid attack it only slowly, but it dissolves readily in nitric acid. Caustic alkali lyes have no action upon the metal. Nickel is a very ductile and highly malleable metal for various purposes. Besides its use in forming highly serviceable alloys with copper and zinc, of which German silver and some of the white compounds used for coinage on the continent of Europe are made, nickel is used chiefly for nickel-plating, for chemical vessels, and, as has been stated, for coating iron cooking-pots in thin layers. An electro-deposit of nickel on steel instruments, such as those used in surgery, is specially useful in preventing rust. Magnets are sometimes made of nickel, and the strongest magnets are probably made of nickel iron. Nickel is used as a base for nickel plating, for chemical vessels, and, as has been stated, for coating iron cooking-pots in thin layers.

Nickel is used in the preparation of Smalt (q.v.), from complex arseniferous nickel and cobalt ores previously roasted. In this process the cobalt practically all passes into the blue glass of which small consists.

Smelting. — At the older nickel-works in different parts of Europe much of the nickel produced is extracted from ores or from regalis, in either of which the metal has become concentrated, and may amount to from 30 to 60 per cent. A good deal of secrecy has been observed regarding the smelting of nickel, but accounts of some of the processes in use have been published. Briefly stated, one of

Nicias
these consists in removing by suitable methods the metals other than nickel in the speiss, in getting the hydroxide of nickel, forming an alkaline arsenite which is soluble in water, and in obtaining a sulfide of nickel which is usually mixed with a small quantity of cobalt. This sulfide when boiled with sulphuric acid yields sulphate of nickel, from which potash precipitates the hydrated oxide mixed with a little cobalt. The separation of the oxides of nickel and cobalt is effected by dissolving the mixture of them in an acid, neutralising, and adding a slight excess of nitrite of potassium and acetic acid. After a few hours the double nitrite of cobalt and potassium is deposited, while the following formula only the nitrite of cobalt is precipitated by caustic potash and redissolved in oxalic acid. When the oxalate of nickel is heated in a wind-furnace fused metallic nickel is obtained.

The New Caledonia ore (garnierite) is smelted by one process in this way. It is placed along with limestone and coke or charcoal in a furnace about 16 feet high with tuyères. Here a regulus is produced with 60 or 70 per cent. of nickel, and containing also some iron, some carbon, and sometimes a little sulphur. This is manipulated in a Siemens' furnace to remove the iron, and also sulphur, copper, and the nickel is then reacted with oxide of manganese and alkaline flux in a plumbago cernible.

**Oxides of Nickel.**—These are nickel monoxide, NiO, the hydrate of this oxide, Ni(OH)₂—both of which are green—and nickel anhydride, Ni₃O₄, which is a black powder. The monoxide of nickel is used to give a soft brown colour to pottery.

**Salts of Nickel.**—Of these Roscoe and Schorlemmer, in their Treatise on Chemistry, say they are derived from the monoxide. In the anhydrous condition they are usually yellowish-brown, while in the hydrate they are light and combined with colourless acids they possess an apple-green to an emerald-green colour. The soluble normal salts have a slightly acid reaction and a sweetish, astringent, metallic taste, and act as emetics.

**Nicker** (A.S. niger, pl. niceras, in Beowulf), a malignant kind of water-sprite in Teutonic mythology. He often presents himself on the shore in the shape of a horse, and has thus close affinities with the Scotch kelpie; while indeed the Old Norse níkr (Old High Ger. nictus) is thought by some to mean the hippopotamus only. In our own demonology we find both a male níkr and a female níkra. They were (as we at present think) an ordinary mischievous spirit or devil, recalling our own familiar Old Nick.

**Nicobar Islands,** a group of islands in the Indian Ocean, forming with the Andamans, to the south of which group they lie, an extension of the great island chain of which Java and Sumatra are the principal links. Just a score in number, of which twelve are inhabited, they consist of two divisions—the northern, low and planted with coconut trees, and the southern, mountainous (2000 feet) and covered with timber. Makira prevails nearly all the year round; the temperature seldom moves outside the limits 80°-85° F. The people belong to two races, an inland tribe, little civilised, who show Mongol traits and are regarded as Indians, and the coast people, about 6000 in number, who are of mixed Malay blood, but idle and lazy. They collect and export trepang and edible birds' nests. The archipelago was occupied by Denmark from 1756 to 1856. In 1869 it was annexed by Britain, to put an end to the piracy of the people. A penal colony for India exists at Nankauri on the island Kamorta (see map at Burma).

**Nicolaus,** CHRISTOPH FRIEDRICH, author, bookseller, and publisher, was born 18th March 1733, at Berlin, where his father was also a bookseller. He early distinguished himself by a series of critical letters (1765) in which he exposed the errors of both Gottsched and Becker in the plan of the controversy which was agitating the literary world of Germany. With Moses Mendelssohn he edited the Bibliothek der schönen Wissenschaften (1757-58), and contributed with Lessing to Briefe an die neue Zeitgenossen (1759-63). By this he was led to conceive the plan of a neue deutsche Bibliothek (106 vols. 1765-92), a periodical which he edited for many years, and which contributed to the progress of literature and improvement of taste in Germany, but became ridiculous from the inability of its editors to agree. A similar spirit the last few years was stirring in Berlin, under Goethe, Schiller, Kant, and others, with all of whom he was at feud. He wrote topographical works, satires, anecdotes of Frederick the Great, and an autobiography, in which he describes strange apparitions of obvious identifications by which he was visited. He died 8th January 1811.

**Nicolaus, OTTO,** musical composer, born at Königsberg, 9th June 1810. His early life was a struggle with poverty and difficulties. He studied in Berlin and in Rome, and in 1847 became Kapellmeister at Berlin. His best-known work is the opera *The Merry Wives of Windsor* (1848). He died 11th May 1849.

**Nicolaitiens,** an immortal sect mentioned in Rev. 6, 15, and sometimes, but apparently on very feeble grounds, connected with Nicolaus the proselyte of Antioch, mentioned in Acts, vi. 3. Indeed the name seems rather to be symbolic than historical, the Greek *Nikolaos* being an equivalent to the Hebrew *Balserin*. In this sense the passage in the Apocalypse harmonises exactly with what is said of the followers of Balserm in Jude and 2 Peter, and Rev. ii. 15 need not be taken as referring to a different class from verse 14. Their error was a licentiousness which they brought into the Christian church from the heathen world, and the subtler wickedness of defending this as supported by a doctrine and a prophetic illumination (2 Pet. ii. 1). There is no satisfactory evidence of the existence of such a sect after the time of John; still Fresins mentions the Nicolaitiens as a sect of Gnostics of the Ophite class, and in this he is followed by the capitolians.

**Nicolas,** St. the patron saint of Russia, whose life is wrapped in an obscurity that is but little lighted by fable. He was bishop of Myra in Lycia, and according to Metaphrases was imprisoned under Diocletian and released under Constantine. The statement that he was present at the Council of Nice is in the highest degree improbable. His supposed relics were conveyed from the East to Ileri, in the kingdom of Naples, on 9th May 1057; and it is a curious fact that in the Russian Church the anniversary of this translation is still observed as a festival. In Catholic countries Nicolaus is especially loved by young, and particularly of scholars. In England his feast was celebrated in ancient times with great solemnity in the public schools, Eton, Sarum Cathedral, and elsewhere; and still in Germany on the vigil of his feast, which is held on the 6th December, a person in the appearance and costume of a bishop assembles the children of a family or of a school, and distributes among them, to the good children, gilt nuts, sweetmeats, and other little presents, as the reward of good conduct; to the naughty ones, the redoubtable punishment of the *Klaue und der Santa Claus*. The institution of the Christmas game, introduced into England from America; the old Dutch settlers of New York kept a Santa Claus holiday. St Nicolas was also the patron of merchants, sailors, and travellers; and as he was prayed
to for protection against robbers, the term 'Clerks of St Nicholas' came, oddly enough, to be a cant name for robbers.

**Nicolas, Sir Nicholas Harris, antiquary,** was born 10th March 1799, of a Cornish family of Breton origin. He entered the navy, and had reached the rank of lieutenant by 1815, but at the close of the war left the service to study law, and was called to the bar, where he devoted himself chiefly to genealogical and historical studies, and his great work, the *History of the Orders of Knighthood of the British Empire* (4 vols. 1841-42), remains a solid monument of learning. Harris was made K.H. in 1831, and K.C.M.G. in 1840, and died aged eighty, at his residence in Dusseldorf, August 3d, 1848. He devoted the energies of his later years to works on the naval history of England: *Dispatches and Letters of Admiral Lord Viscount Nelson* (7 vols. 1844-46), and the unfinished *History of the British Navy* (2 vols. 1847), as well as the papers of Sir Hudson Lowe. Harris wrote biographical notices of many of the poets in Pickering's Aldine edition, as well as many useful historical handbooks, as a *Synopsis of the Peerage of England* (1823), *Testamenta Vetusta* (1826), the *Chronology of History* (1835), *Proceedings and Ordinances of the Privy Council of England* (7 vols. 1833-37); a *Life of William Davison*, Queen Elizabeth's secretary and scapegoat in the execution of Mary, and an ancestor of his wife's (1823); *Memoirs of Ritten* (1833); and a host of books and pamphlets—and all in verse—on heraldic, genealogical, antiquarian, and historical questions. A list of these is given in the Gentleman's Magazine for October 1848.

**Nicole, Pierre** (1623-93), one of the most distinguished of the Port Royalists (see *Port Royal Des Champs*), the friend of Arnauld and Pascal. See also JABBIN.

**Nicoll, Robert,** minor Scottish poet, was born the son of a small struggling farmer at Little Tullybeltane, in the Perthshire parish of Auchtergaven, 7th January 1814. He was four years a grocer's apprentice at Perth, next opened a circulating library in Dundee, and here took to writing for the newspapers, and published, variously, *Songs and Lyrics* (1835). In 1836 he became editor at a salary of £100 of an ultra-radical weekly, the *Leeds Times*, but worked too zealously for his health, and gave himself his death-blow by his exertions in the victorious contest of Sir Walter Scott, with the *Northern Star*, in the summer of 1837. He went north for rest, only to die of consumption at Trinity, near Edinburgh, 7th December 1837. He was buried in North Leith Churchyard. Beyond a doubt Nicoll was a genuine poet, and moreover it must ever be remembered that he died at twenty-three. But it is far more from their intrinsic value than the mere pathos of his story that his countrymen remember such poems as 'We are Brethren a,' 'Thoughts of Heaven,' and 'The Dew is on the Summer's Grass.'

See the *Life* by Mrs Johnstone, first prefixed to the 1842 edition of the poems; that prefixed to the Paisley edition (1877); and the somewhat uncritical life, by P. E. Drummond (published posthumously, 1884).

**Nicomeedia,** the capital of ancient Bithynia, situated at the north-eastern angle of an inlet of the Propontis, was built in 564 B.C. by Nicomedes I. It soon became one of the most magnificent and flourishing cities in the world, and some of the later Roman emperors, such as Diocletian and Constantine the Great, selected it for their temporary residence, and transformed it into a city of earthquakes. Hannibal committed suicide in a castle close by, and Constantine died near the city, which was the birthplace of the historian Arrian. The small town of Ismid now occupies its site. See *Bithynia* for Nicomedes.

**Nicopolis,** a town of Bulgaria, with 5031 inhabitants, is on the Danube, 56 miles W. of Rustchuk. The Berlin Congress of 1878 provided for the demolition of the fortifications. Here the Huns, according to the story related by the Historian of 1248, and the place has been more than once taken by the Russians (1810, 1827, 1877).

**Nicosia,** (1) called also LEVKYOSIA, the capital of Cyprus, situated near the middle of the northern half of the island, is surrounded with old Venetian walls, and is the residence of the British High Commissioner, and the see of a Greek archbishop. There are numerous mosques and churches, and some manufactures of silk, leather, and cotton. Pop. (1891) 12,515.—(2) A city of Sicily, 40 miles N.W. of Catania. Pop. 15,576.

**Nicol, Jean,** born at Nimes in 1530, died at Paris in 1600, French ambassador at Lisbon, introduced into France the tobacco-plant, which was called after him Nicotiana (see TOBACCO). He also compiled one of the first French dictionaries, *Trésor de la Langue Française* (1606).

**Nicotine,** C$_7$H$_7$N$_2$, is a volatile liquid alkaloid, and constitutes the active principle of the tobacco-plant, in all parts of which it occurs in combination with volatile and insoluble bodies. It is likewise contained in minute amount in the smoke of the burning leaves. When pure and freshly prepared it is a colourless, intensely poisonous liquid, which evolves a very irritating odour of tobacco, but on exposure to the air it rapidly oxides and becomes brown in colour. It is moderately soluble in water, and dissolves readily in alcohol and ether. The quantity of nicotine in tobacco varies from 2 to 8 per cent.; the coarser kinds contain the larger quantity, while the best Havana cigars seldom have more than 2 per cent., and often less. Locally, nicotine is very irritating. Taken internally, it is one of the most powerful poisons known; 1/4 grain taken by the mouth has caused in man distinct symptoms of poisoning, there being first seen a short stage of excitement, followed by headache, vertigo, great weakness, and general depression. In the doses (1/4 grain) caused in addition trembling, vomiting, collapse, and great depression of the heart and respiration. A single drop is sufficient to kill a rabbit or cat in a few minutes. It has been used rarely for homicidal and suicidal purposes in the minimum lethal dose in man is not accurately known.

**Nectitating Membrane, or Third Eyelid.** See BIRD, and EYE.

**Nidderdale,** the valley of the river Nidd, which rises at the foot of Whernside, in Yorkshire, and flows south-east and east, and joins the Ouse a few miles above York. The upper portion of the stream flows through picturesque scenery and east TransPennine. The birthplace of Eugene Aram. Above Lofthouse it disappears underground for about two miles. See Joseph Lucas's *Studies in Nidderdale* (1882).

**Niebelungen.** See NIEBELUNGENLIED.

**Niebuhr, Barthold Georg,** one of the most distinguished of modern historians, was born August 27, 1776, at Copenhagen, the son of the famous travel writer, Niebuhr. From his infancy he showed unusual promise, and he was carefully educated under his father's eye. After his studies at Kiel he became private secretary to Count Schimmelmann in Copenhagen, and devoted himself to the study of the Dutch. He went to London and Edinburgh (1798-99). In 1800 he married and entered the Danish state-service, and
Niebuhr, Neften, a distinguished geographer and traveller, was born in 1733, in the Hanoverian duchy of Brunswick, and after several years as a day-labourer; but having acquired a small property, he studied at Göttingen, entered the Danish service, and in 1761 joined an expedition to explore portions of Arabia, Persia, Asiatic Turkey, and India. On his return to Denmark in 1767, he published the results of his mission, Description de l'Arabie (Copenhagen, 1772), and Reisebeschreibungen (3 vols. 1774-98). He also edited and published at his own cost the natural history notes of his deceased friend and fellow-traveller, P. Forskål, Descriptiones Animales (1775) and Flora Aegyptiaca (1778), and his work on Arabia.

Niebuhr, NEBEN, given classical 1867, but also the other the the the not Fall 1880). black VoU extraordinary Other 1817 first bronze See Gaia; end his 2d powerful 2007 these He gave (1810-12) a course of lectures on Roman history which, by making known the results of the new and critical theory that he had applied to the elucidation of obscure historical evidence, established his position as one of the most original and influential historians of his time. His appointment, in 1816, to the post of Prussian ambassador at the papal court, where he remained till 1823, gave him an opportunity of testing on the spot the accuracy of his conjectures in regard to many questions of local and social bearing. On his return from Rome Niebuhr took up his residence at Broum, where his admirable lectures gave a powerful impetus to classical and archaeological learning. He was thus employed when the revolution of 1830 resumed him from the calm of his literary pursuits. His sensitive nature, unstrung by physical weakness, enabled him to form an exaggerated view of the consequences of this movement, and to anticipate a recurrence of all the horrors of the former French revolution, and the result was to bring about a state of mental depression and bodily prostration, which ended in his death, 21 January 1831. Niebuhr's attainments were of extraordinary range, and his genius strikingly original in cast. He had mastered twenty languages before the age of thirty, and his tenacious memory retained everything he read; while he possessed in a remarkable degree the gift of intuitive sagacity that enabled him also to supply an unworn false evidence. He was often to supply by felicitous conjecture the link wanting in some imperfect chain of evidence. It is not to be denied, however, that his scepticism as to the credibility of early history goes too far, and that he is often arbitrary and unhistorical in his conjectures; indeed, the stricter sort of sceptical critics, like the late Sir George Cornewall Lewis, go so far as to regard his effort to construct a continuous Roman history out of such legendary materials as we possess as, on the whole, a failure. Niebuhr's discovery and correction of the errors of the earlier Roman history from still earlier ballads is now accepted by scholars; but the fact remains that the bulk of his contribution to history still stands substantially unshaken, and it would be difficult to overestimate the strength of the impetus he gave to its study on a really scientific method.

Of his Römische Geschichtle (vols. i. and ii. 1811-12; 2d ed. 1827-28; 3d ed. 1837-39); other works translated from Schmitz into English are Lectures on the Hist. of Rome, to Fall of Western Empire (2d ed. 3 vols. 1830), Lectures on Ancient Hist. (3 vols. 1832), and Lectures on Ancient Ethno- graphy and Geog. (2 vols. 1833). Other works are Grieche. Heroyergeschichte (1842), written for his son Marcus; Kleine historischen und philologischen Schrif- ten (1852), besides many other works on philological, historical, and archaeological questions. Niebuhr co-operated with Bekker and others in re-editing Scriptores Historiae Byzantiae; he also discovered historical fragments in the edition of Cicero's Orations and portions of Galus; published the Inscriptiones Nabiscienses (Rome, 1821); and was a constant contributor to the literary journals of Germany. See Dehler, Niebuhr's Leben und Werke (1838; Eng. trans. by Miss Winkworth, 3 vols. 1852), and the studies by Cassen (1876) and Dyussenhardt (1896).
Memel, rises a few miles south of Minsk, and its two branches reach the Kurisches Haff each by four mouths. See Tilsit.

Niepe, Joseph Nicéphore, was born at Châlonsur-Saône, 7th March 1765, served in the army in Italy, and in 1795 became administrator of the district of Calais, and returning to Châlons in 1801, he made those experiments with sunlight pictures which made Photography (q.v.) possible. He died 6th July 1853.-His nephew, CLAUDE MARIE FRANÇOIS NIEPCE DE ST VICTOR (1805-70), also a soldier, wrote a Traité Pratique (1856) on Photography, and Recherches Photographiques (1855). [Proc. Nee-gppa.]

Nierstein, a Hessian village on the Rhine, 10 miles S.S.E. of Mainz, famous for its wine. Pop. 3283.

Nietzsche, Friedrich Wilhelm, born the son of a pastor at Röcken in Saxony, 15th October 1844, studied at Bonn and Leipzig, and obtained distinction by treatises on Thucydides, on the origin of tragedy, &c. But from 1874 he began in a long series of works to expound a revolutionary philosophy denouncing all religion and treating all moral laws as a remnant of Christian superstition, cherishing the 'virtues of the weak.' His ideal, 'the overman,' is to be developed by giving unbridled freedom to the struggle for existence; will seek only his own power and pleasure, and knows nothing of pity. A translation by Tille of eight volumes of his works began in 1896 with Thus spake Zarathustra. The innate of an insane asylum inmate, he died 25th August at 59. See Quarterly Review, October 1896.

Niemweld. See Cape Colony.

Nièvre, a central department of France, on the watershed between the Loire and the Seine. Area, 26,532 sq. m.; pop. (1881) 347,576; (1891) 343,581. Mountains of the Morvan system, which forms the watershed between the Seine and Rhone, divide the department into two great declivities. There are plateau more or less fertile, vine-clad hills, and valleys rich in pastures; but the principal wealth of the department consists in its forests and minerals—coal, iron, and gypsum. The Nièvre is an inconsiderable affluent of the Loire from the right. The rivers are the Arnon, Loire, Loing, and Yonne. The iron industry is important, and pottery and glass are manufactured. Arrondissements, Nevers, Château-Chinon, Clamecy, and Cosne; capital, Nevers.

Nifflheim. See Scandinavian Mythology.

Nigella, a genus of plants of the natural order Ranunculaceae, having five coloured spreading sepals; five or ten small two-lipped petals, with tubular claw; the carpels more or less connected together, many-seeded; the leaves divided into threadlike segments, the flowers solitary at the top of the stem or branches. They are annuals, natives chiefly of the countries near the Mediterranean, and a few of Asia. Some of them, occasionally seen in gardens in Britain, are vulgarly known as Devil-in-a-mist. The seeds are aromatic and somewhat peppery. Those of N. sativa, a species common in cornfields in the south of Europe, are supposed to be the Black Caraway the ancients, and perhaps the Cabimion of the Bible.

Niger, the name now generally applied to one of the most remarkable river-systems of West Equatorial Africa, first appears in Ptolemy as designating, it is believed, the modern Wadi Draa, and subsequently the river Gir, which may be identified with the modern Gour-Gour, flowing southward from the Atlas towards the oases of Taza. The word not improbably contains the root gir, gar, or jor, not infrequent in the river-names of northern Africa. Mixed up as it was from time to time with the problem of the Nile, the problem of the Niger remained almost till the 19th century one of the most perplexed and bemedled in all the whole land of geography. By the year 1870, the course that the river had ascended the river from the sea in the 16th century, the most contradictory opinions were held as to its character and relations down to the later part of the 18th century: it was an affluent of the Nile; an affluent of the Congo; an independent river terminating in an inland basin; and so on. It was still left to Mungo Park and other workers in the service of the African Association (1788) to lay the basis of our present fairly accurate knowledge of the system. Apart from some of the tributary streams, the hundred years of exploration now leave only a blank of some 60 or 70 miles in the middle course of the main river.

The Niger proper (Joliba or Dhiiluba, Issa, Kwarra or Qoromp, &c.) has a total length of 2500 miles, and the area of the entire basin (including that of the Benue) is estimated at 1,023,280 sq. m. The head-waters are situated in the region now known as the States of Samory, inland from Sierra Leone and Liberia, and are contiguous to the head-waters of the Senegal. The Tembi (first explored by the Zweifel and his party in 1838), the master river of the basin, has a height of about 3000 feet above the sea in the Loua Mountains in 8° 36' N. lat. and 10° 33' W. long., is now accepted as the conventional 'source.' This and its sister streams, though draining a comparatively limited area, soon gather into a good navigable river, which holds its own course as far as Timbuktu (18° 4' N. lat., 1° 45' W. long.), first visited by Laing in 1836. About 300 miles above this famous city it is joined by an important right-hand tributary, the Mayel-Baleul, and develops a tendency to split up into numerous and widely diverging channels, with cross-erocks, back-waters, and swamps. Beyond Timbuktu a more easterly direction is maintained for 200 miles, and then with its new united forces the Niger turns south-east to cut its way through a rocky tract of country, and to pass in succession the two (Gogo and Toumba) of the southern termini of the present Niger, and Bana, the southern point of Barth's exploration; Gompa, the northern limit of Flegel and Thomson; Bussa, where Park came to his untimely end; Rabbin, one of the largest cities on its course; and Egga, where the river, having struck across the Keneuf Valley (2000 feet), turns south-west. During this long journey from Timbuktu (1130 miles) a chief characteristic of the Niger has been the insignificance of its tributary streams; but at last, in 7° 50' N. lat. and 6° 45' E. long., it meets in the Benue or Mother of Waters a rival both in volume and in beauty. This river has travelled 800 miles from the east; and, though exploration in 1890 has deprived it of the credit (hypothetically assigned) of being a link through the Toubou swamp with the system of Lake Tsand, it has interest enough, given its simple and competent beauty. The united river, leaving the sandstone plateau through which it has been carving its channel, 'passes through a series of bold, picturesque hills by a narrow gorge,' and below Onitsha begins to break up into one of the most remarkable mountainous-evergreen-valleys in the world, as shown in the section, paper and map, in Proc. Roy. Geog. Soc. 1888.

The greater bulk of the exploration of the Niger (especially towards the south) has been accomplished by Britain (Park, Clapperton, Beecroft, Trotter, Hailstone, &c.), thanks mainly to Mac Gregor Loraine, who founded the African Steamship Company in 1832. Britain has held her ground against all foreign commercial competition. By the Berlin Conference of 1884 the whole course of
the river below Timbuctu (while its navigation is declared free) is placed under the protection of Britain; and the British United African Company (founded 1870, chartered 1886), with its stations at Akasa, Onibasha, Assaba, Lokoko, &c., has practical command of the trade. The English Church Missionary Society has long laboured in the delta region and inland as far as possible; and in 1864 Bishop Crowther was appointed to the bishopric of the Niger. Above Timbuctu the control is in the hands of the French, who have steamers on the river, but have no influence in French Sudan, Soudan, and Kangua, and Bannako, and are rapidly pushing eastwards. Germany made a strong effort, mainly through Fiegel, to seize the control on the Benin, but was thwarted by the United African Company. For a long time slaves were almost the only articles of export from the Niger; at a later date palm-oil became so distinctly the staple that the name Oil Rivers was given to the various outlets of the delta in which the Niger proper interlaces with several seaboard streams. The Royal Niger Company, which has made exclusive treaties with Soudan, Benin, and other states, is governed by an board in London: the Oil Rivers is, since 1892, a British protectorate. The British sphere accordingly now extends from the Bight of Benin to Say on the Niger, and from Lagos to Lake Tadz (Chad). North of this line from Say to Barrawa on Lake Tadz is a British protectorate. East of a line from the Cross River to beyond Yola on the Benin is German.

See Joseph Thomson, Mungo Park and the Niger (1890); Mockler-Ferryman, Up the Niger (1893); and Kellett, The Partition of Africa (1893).

Night. See DAY. —Amongst the ancient Greeks Night (Nycte) was personified as a powerful goddess, who was supposed to lead men and gods. According to Hesiod, she was the daughter of Chaos, wife of Erebus, and mother of Aether and Hemera (Day), of the Fates, Sleep, Death, Dreams, Hunger, Fear, Nemesis, and Strife.

Night-hawk, the normal name in the United States for the Chordeiles papuica, a goatsucker belonging to a different genus and species of the Caprimulgidae from the European Goatsucker (q.v.).

Night-heron (Nycticorax), one of the genera of Herodiones (see HERONS), cosmopolitan in its distribution, and including nine species. One species, N. mulieris, is widely distributed over the whole of Africa and southern Asia, breeding in the Spanish peninsula and in Italy, and a migrant to places near the Baltic, has now, since the year 1872 when it was first recorded near London, become an almost annual visitor to various parts of the British Islands in spring and autumn, and would probably breed if un molested. It is about 22 inches long; it nests in colonies on trees or bushes in swamps, or on reeds strongly built together in a pile, and feeds on water insects and their larvae, worms, snails, small fish, and frogs. Closely allied forms inhabit the African (Nycticorax Garibaldi), Bahr), the common American night-heron, being found all over the United States, as a permanent resident in the southern portion only; and in the Malay-Australian region N. catonlicus, a distinct species, occurs.

Nightingale (Daulis) a genus of Passerine birds of the family Turdidae. The bill is straight, slender, not quite so long as the head; the wings do not much pass beyond the base of the tail; the first quill is very short, the third is the longest; the tail is slightly rounded; toes long, claws rather short. The Common Nightingale (D. fuscus) is well known as the finest of songsters. It is rather larger than the hedge-sparrow, with about the same proportionate length of wings and tail. It is of a rich russet-brown colour above, shudding into reddish chestnut on the tail-coverts and tail; the lower part greyish white; bill, legs, and feet brown. The sexes are alike in plumage. It is a native of many parts of Europe and Asia, and of the north of Africa, extending as far as to Abyssinia, and to the Gold Coast in West Africa, and is a bird of passage, extending its summer migrations on the continent of Europe as far north as the south of Sweden, though in Britain it has sometimes been seen farther north than Yorkshire. It is plentiful in some parts of the south and east of England, but is less common in the western counties, and does not visit Scotland, Ireland, or Wales, except Glamorganshire and Brecon. It frequents thickets and hedges and damp meadows near streams. The market garden near London are among its favourite haunts. It feeds very much on worms, beetles, insects, ants' eggs, caterpillars and other insect larvae. It arrives in England about the middle of April, the males about ten days before the females. It is at this season, and before pairing has taken place, that bird-catchers generally procure nightingales for cage-bird fanciers, and they then become easily reconciled to confinement, whilst if taken after pairing they fret and pine till they die. If nightingales, however, are to be kept in confinement they ought to be taken from the nest when young and reared by the hand. The nightingale makes its nest generally on the ground, but sometimes on a low fork of a bush. The nest is loosely constructed of dead leaves, rushes, and stalks of grass, with a lining of finer materials. The eggs are from four to six in number, of a uniform deep olive-brown. The song of the male ceases to be heard as soon as incubation is over. In captivity, however, it is often continued through a more considerable period. The nightingale usually begins its song in the evening, and sings with brief intervals throughout the night. The variety, loudness, and richness of its notes are equally extraordinary; and its long quivering strains are full of plaintiveness as well as of passionate ecstasy. The nightingale has been a favourite from most ancient times, and is often mentioned in the poetry of India and Persia, of Greece and Rome, as well as by Shakespeare and Herrick, Kents and Coloridige, and many others. The loves of the Bulbul (q.v.) and the rose are a favouiable theme in which eastern poets delight. The nightingale, as a rule, is a shy bird, for although it is but seldom seen it seems to prefer to live near the abode of man; nor is it quarrelsome with others of its own species except at pairing time. A closely allied species (D. goliath) is found from the Caucasus to Turkestan and Persia, and in northeastern and central Europe the Northern Nightingale or Sprosser (D. philomela) is found, quite a
distinct species, of rather larger size, less russet in hue, and slightly spotted on the breast.

**Nightingale**, FLORENCE, the daughter of William Edward Nightingale of Embley Park, Hampshire, and Lea Hurst, Derbyshire, was born at Paddington, May 12th, 1820. She was taught mathematics, the classics, and modern languages under the guidance of her father, and thus highly educated and brilliantly accomplished she early exhibited an intense devotion to the alleviation of suffering, which in 1844 led her to give attendance to the condition of the wounded of the Crimean War. She visited the field and inspected civil and military hospitals all over Europe; and in 1851 went into training as a nurse in the institution of Protestant Deaconesses at Kaiserswerth on the Rhine, and studied with the Sisters of St Vincent de Paul in Paris the system of nursing and management carried out in the hospitals of that city. On her return to England she put into thorough working order the Sanatorium for Governesses in Harley Street. Ten years was the term of apprenticeship thus served in preparation for the work of her life. In the spring of 1854 war to re-neat an ostensibly far-off war was fought on the 20th of September, and the wounded from the battle were sent down to the hospitals on the Bosphorus, which were soon crowded with sick and wounded, their unhealthy condition becoming apparent in a rate of mortality to which the casuistry of the first great battle was as nothing; in this crisis Miss Nightingale wrote on 15th October and offered to go out and organise a nursing department at Scutari. Lord Herbert, who had already written a letter requesting her to go, which encouraged that containing Miss Nightingale's offer, gladly accepted, and on the 21st of October she departed with thirty-four nurses. She arrived at Constantinople on the 4th of November, the eve of Inckerman—the beginning of the terrible winter campaign—in time to receive the wounded from the second battle in ward already filled with 2300 patients. Her devotion to the sufferers can never be forgotten. She would stand twenty hours at a stretch, in order to see them provided with accommodation and all the requisites of their condition, and a few months after her arrival she had 100 beds under her care in the tents. She clearly in the bad sanitary arrangements of the hospitals the causes of their frightful mortality, and her incessant labour was devoted to the removal of these causes, as well as to the mitigation of their effects. In the spring of 1855, while in the Crimean, set with brilliants from the Sultan of Turkey, she was prostrated with fever, the result of unintermitting toil and anxiety; yet she refused to leave her post, and on her recovery remained at Scutari till Turkey was evacuated by the British, July 28, 1856. She, to whom many a soldier owed life and health, had expended her own health in the physical and mental strain to which she had subjected herself. In 1857 she furnished the commissioners appointed to inquire into the regulations affecting the sanitary condition of the British army with a paper of written evidence, in which she impresses upon them clearly the great lesson of the Crimean war, which she characterises as a sanitary experiment on a colossal scale. At the close of the Crimean war a fund of £30,000 was subscribed for the purpose of enabling her to provide for the training of nurses; this is spent in training a superior order of nurses in connection with St Thomas's (the Nightingale Home) and at King's College Hospital. From the Queen she received an autograph letter of thanks, and a cross set with diamonds, as also a bracelet set with brilliants from the Sultan of Turkey. Her experience in the Crimea turned the attention of Miss Nightingale to the general question of army sanitary reform, and first to that of army hospitals. In 1858 she published her valuable *Notes on Nursing*, and she contributed two papers to the National Association for the Promotion of Social Science, on Hospital Construction and Arrangement. The *Notes on Hospitals* (1859), from their clearness of arrangement and minuteness of detail, are most valuable to the architect, the engineer, and the medical officer. In the year 1863 was issued the Report of the Commission on the Sanitary Condition of the Army in England. These reports were sent in manuscript to Miss Nightingale, and at page 347 of vol. i. are inserted her incisive and admirable observations upon this immense mass of evidence. In 1871 Miss Nightingale published *Notes on Lying-in-Institutions*; in 1873, *Life or Death in India* and (in Fraser's Magazine) 'A "Note" of Interrogation,' which attracted a good deal of attention, mainly on account of the way she handles religious beliefs and life. From America and from different European governments her advice has been sought as to army sanitation; she assisted in founding the Red Cross society. The Longfellow's *Santa Filomena* is in her praise. The article HOSPITALS in this Encyclopaedia is from her pen.

**Nightjar**. See Goatsucker.

**Nightmare** (A.S. neacht, 'night,' and mare, 'night-mare,' originally 'the crusader'). See Dreaming.

**Nightshade**, the English name of certain plants of the natural order Solanaeae (q.v.), possessing the narcotic properties frequently developed in that order. Among them are some species of *Solanum* (q.v.), particularly the Common Nightshade, or Black Nightshade (*S. nigrum*), an annual or biennial, with erect angular stem, ovate, spinato-dentate leaves, drooping lateral umbels of whiteflowers, and globose black berries; a frequent weed in waste places in England and in most parts of the world. Few plants are more widely diffused. It is only slightly narcotic. The leaves in a fresh state are said to be injurious to animals which eat them, but seem to lose almost all narcotic property by boiling, and are used as spinach, particularly in warm climates. The berries, Belladonna generally dreaded or suspected, may also, it is said, be eaten, at least in moderate quantity, without danger. They contain, however, the alkaloid *Solanine*, found also in the shoots of the potato. For the White Nightshade, see BITTERSWEET; for the Deadly Nightshade, see BELLADONNA; and for Enchanter's Nightshade, see CIRCEA.

**Nigritia**. See SOUDAN.

**Nikita**, a seaport of western Japan, situated on a narrow strip of land at the mouth of the Shinano River, was opened to foreign trade in 1858. The harbour does not admit of the entrance of vessels of foreign build, and the roadstead is exposed; the foreign trade has therefore remained
only nominal. The apples and water-melons of the province are noted for their excellence. Pop. 1860 49,874.

Nihilism is a term used to describe certain negative systems of philosophy. It was applied to some rationalists in the 12th century (Peter Lombard, q.v.), and in modern times to various negative systems of metaphysics, ethics, and atheist philosophy. Of late, however, it has become familiar as applied to Russian revolutionists, and especially (though improperly) to those of the 'terrorist' wing. In Russian life it was first introduced by Turgenev (q.v.), in Fathers and Sons (1862), to characterise a new type appearing at that time among the Russian educated classes—men who, in Turgenev, had an aggregate of 3,000 no authority of any kind, and accept on faith no principle, whatever veneration surround it.' Accordingly, they defined 'the fathers' to find out, in our present life, family and social, one single institution which would not deserve an absolute and pitiless negation;' and, 'abandoning all talk about art, unconscious artistic creation, parliamentarism, reformed tribunals, and what not else,' they put above all 'the question of daily bread for all,' repudiated art as long as it is not in the service of the masses, waged war against prejudices, and reformed life in general on a truth of sincerity, assuming an outward roughness in their behaviour as a protest against the polished and insincere relations in civilised life. Turgenev's eminently objective description of the new type having been misunderstood, Tchernyshevsky (q.v.) wrote the novel What is to be done? representing the Nihilists not as simple philosophers of negation, but as people engaged either in science, or in social reforms on Robert Owen's lines, or (a few of them) as popular revolutionists; and especially insisting upon their highly respectful relations to woman, whom they consider as an intellectually equal comrade in work. The two novels, both drawn from life, thus complete one another, and give a correct idea of Nihilism, which in its philosophical aspects is an outcome of the philosophy of the 18th century as modified by modern ideas. Dostoevsky and M. S. Mill being the most popular authors among Nihilists), while in social life it appears as a protest against 'the conventional lies of civilised mankind.' Nihilism is thus the Russian equivalent of the 18th century's Scottish and French Encyclopedists, and of the 19th century's German Idealist school, in which makes them differ so widely from literature and art in western Europe. They also contributed to the deep-reaching movement in favour of the higher education of Russian women, which, not withstanding the opposition of government, is now further advanced. In Russia the number of educational institutions and art in the country. The 324 non-classical gymnasia for girls—quite equal to the best institutions of the same kind—have now 90,000 pupils. Four women's universities and one medical academy, all supported by the government, are engaged in education and quite equal to the best male universities. They have obtained doctors' degrees in Russia after having passed the same examinations as the male doctors. * Nihilism was found in all classes of educated Russians, the greater part taking whatever in the political struggle; while these revolutionists who are described in western Europe as Nihilists have political programmes directly borrowed from western Europe, and are known in Russia as Socialists, Anarchists, Populists, or Party of the Will of the People. In the latter resorting to political terror in order to obtain a constitution.

The name of Nihilist has, however, been so much identified with the revolutionary movement in Russia that a brief account of the latter must be given under this heading. It was born, especially under the influence of Herzen (q.v.) about 1860, when the hopes of thorough reforms awakened by the proposed emancipation of the serfs were frustrated by the ascendency acquired by the serfs' party in the councils of the czar. Proclamations appealing to the peasants to revolt were issued in 1861; and two secret societies—The Great Russian and 'Land and Liberty,'—were organised. In 1861 the poet Mikhailov (died in Siberia in 1867) and in 1864 Tchernyshevsky (died in 1867 at Astrakhan, after 20 years' confinement in Siberia) wrote the letters to the public which, while upholding the necessity of labour in Siberia in connection with this movement. When, after the Polish insurrection (1863), the old party took the upper hand in the Winter Palace, new revolutionary circles made their appearance; they resulted in a peasants' outbreak at Kazan (1864), a revolutionary propaganda among workers, and an attempt by Karakozoff upon the life of the czar (1866). In 1870 a similar movement was started among the youth under the leadership of Netchatief. The failure of these two movements led to the appearance all over Russia of circles for more serious self-education, which, however, soon took a more revolutionary character, chiefly under the influence of the powerful agitator, Michel Bakunin (q.v.), the ideas of the International Working-men's Association, which rapidly spread in Russia after the Paris Commune, and the socialist writings of Colonel Polevoi (q.v.), whose influence caused many of rich families abandoned their homes, and went to the villages and factories in the capacity of workers, schoolmasters in villages, medical help, midwives, and so on, either simply to share with the people their life of privation or to carry on a revolutionary propaganda. There were also in 1870 the so-called Narodniki (q.v.) in connection with the movement and kept for years in prison; but only 183 could be brought (end of 1877) before a supreme court. It could not but acquit most of them; yet even them they were sent into exile. Several smaller groups were tried and condemned during the same years.

The flogging of a prisoner in the St Petersburg prison by the then prefect of police, General Tréfouët—a most influential person among the advisers of the czar—and the impossibility of otherwise bringing the fact to publicity, induced Vera Zasulitch to make an attempt upon General Tréfouët's life (February 1878). She was sent as a common-law offender before a jury and acquitted (April 1878), the attempt at arresting her as she left the court being baffled by a riot in the streets, during which one of her friends, who was a political offences were now withdrawn from the senate (which formerly used to judge them) and assigned to courts-martial; while on the other side the revolutionists, abandoning more and more the propaganda among the people, resorted to a policy of terror. After having been killed an important official, the governor-general of Kharkoff, and the chief of the state police, General Mezentoff, in broad daylight in St Petersburg (August 1878)
Russia was then divided into general governorships, the governors receiving the power of confirming the sentences of death pronounced by the courts-martial, and freely using it. Several attempts against the life of the czar were made: by Solovioff (in April 1879), twice by wrecking imperial trains (November 1879), and finally by a destructive explosion in the Winter Palace (February 1880). Seventeen revolutionists were arrested and exiled to Siberia during the same twelve months. After the Winter Palace explosion Alexander II., who already more and more abandoned the direction of state affairs, nominated Count Loris-Melikoff president of the supreme commission for the management of the affairs of the empire. Write reforms were permitted of constitutional reforms were circulated by the new ruler, but none of them were realised, and the nomination was cancelled a few months later. So the executive committee of the party of the Will of the People, which had since 1883 had ramifications over Russia, and whose secret press always reappeared in spite of the seizure of its printing- offices, prosecuted its underground work, and Alexander II. was killed by bombs March 13, 1881, on the morning of which very day he had signed a decree abolishing serfdom as the Assemblee des Notables. The new czar, Alexander III., after a six weeks' hesitation, dismissed his father's ministers and proclaimed his resolution to remain an absolute sovereign. He lived almost a prisoner in Paul I.'s palace at Tsarskoe Selo and continued to be flanked by police, under the cover of the army and navy. Nicholas II., who succeeded his father in 1894, continued his policy and so became obnoxious to the revolutionists. Public discontent is stirred by the systematic demolition of the reference to the Gospels and other measures which it penetrates among the peasants, who see in the abolition of the justices of peace (1889) and the restrictions imposed upon the provincial self-governments so many steps towards the reindroduction of the monarchical justice of the nobles, and who meet these measures by a series of outbreaks in 1889–90.

Stepanik, Underground Russia (1883; Geschichte der revolutionaren Bewegungen in Russland, by the same author, 1884); Amanace of the Will of the People for 1883 (published at Geneva in Russian, contains all the names and dates, and an historical sketch of the movement); Stepanik, History of the Russian Revolution (1885); E. Norden, The Passion Revolt (1885); *Russia and the Siberian Exiles* (Central Magazine, 1887–89), by George Kennan; the present writer's In Russian and French Prisona (1887); Nizhni as it Is (1885, mainly by Stepanik); other works named at Kropotkin and Stepanik; also ANARCHISM.

Nijnji- Novgorod ("Lower Novgorod"). A famous commercial city of Russia, and capital of a government, is situated at the confluence of the Oka with the Volga, 274 miles E. of Moscow by rail. There is an upper city, containing the Kreml and many of the fifty churches, a lower city, and a suburb. The great fair brings buyers and sellers from all climes between Germany and China. For business purposes the fair lasts nine weeks, and during the fairs, there is an enormous market-hall, and sixty blocks of buildings for booths, containing more than 2900 apartments separated by fireproof walls. There are three annual fairs, two of them in the month of September. The third, beginning at the 15th of July and continuing till September, is still the greatest in the world. But like the fair of Leipzig, it is evident that the great Russian fair is declining in importance. During the fair, the normal population (70,800 in 1855) is increased fivefold or even sevenfold; and the value of the goods sold at the great fair of 1889 was stated at £18,534,277. At these fairs all foreign goods were supplied in smaller quantities, those of Russian origin in abnormally large quantities. Nijnji-Novgorod, founded in 1221, was devastated on several occasions by the Tartars; its prosperity dates from the year 1817, when the great fair was removed to Nijnji-Novgorod from Makarief after a great fire.—The government has an area of 19,797 sq. m. and an estimated population (1853) of 1,680,704, including iron goods, salt, copper, gypsum, wool, and leather.

Nijnji-Tagilsk, a town of the Russian government of Perm, amid the Ural Mountains, 156 miles E. of Perm by rail, with great platinum, copper, and iron works. Pop. 30,000.

Nikolaevsk, a decayed town of eastern Siberia, 23 miles from the mouth of the Amur. Pop. 3500.

Nikolaefff, headquarters of the Russian Black Sea fleet, in the government of Kherson, at the confluence of the Igul with the Bug, and 42 miles from the Black Sea. The joint estuary of the Bug and Dnieper is defended by the forts of Otchakoff and Kinburn; and Nikolaieff is a great fortified naval station, with docks, an arsenal, &c., and has a large trade in river, lake, and canal commerce. The fairs are still being held. Since its connection with the central railway system of Russia its trade and importance have increased rapidly. Pop. (1891) 77,211.

Nikolsburg (Czech Mikulov), a town of Austria, in the south of Moravia, 27 miles S. of Brünn by rail, lies at the foot of hills famous for their rich red wines. In the middle of the town, upon a rock, stands the castle of the princely Dietrichstein family. Pop. 7642.

Nikon (1605–57), the Russian patriarch and prince whose revision of the very incorrect Slavonic service-books caused the secession of the Raskolniks (q.v.).

Nikosa. See NICOSIA.

Nile, the longest river of Africa, if not of the world, hydrographically, historically, and geographically by far the greatest interest, and to the ancient Egyptians pre-eminently the sacred river, draws its largest supplies of water in the country of its sources from the Victoria and Albert Nyanzas. Several streams flow into the Victoria Nyanza, but the largest of them, which is not yet definitely known, the honour seems to lie between the Shimiya and the Isanga. At any rate, the most distant feeders of the great river may probably be placed near to 4° S. lat. The river Kagera or Alexandra Nile, which joins the Victoria Nyanza high up on the west side, is believed to issue from Lake Alexandru, some 250 miles to the south-west; that stream brings a large volume of water to the lake. The Nile leaves Victoria Nyanza at its northern end, pouring over the Ripon Falls, 150 to 170 yards wide but only 12 feet high, and then for 300 miles races between high rocky walls, over rapids and cataracts, at first north-west, then west, until it joins Albert Nyanza near its north-east corner. About 20 miles from this lake the river leaps down 120 feet into a wild gorge, with high rocky walls. The section between the two Nyanzas is called the Victoria Nile or Somersett River. At its south-western extremity the Albert Nyanza is joined by the river Seniliki, which drains away the surplus water of the Albert Edward Nyanza (discovered by Stanley in 1888); and this lake in its turn drains the slopes of the snow-covered Ruwenzori and adjacent mountains. The combined river leaves the northern extremity of the Albert Nyanza as the Baher-el-Jebel, and from that point flows in a general northerly direction to the Mediterranean. The first 130 miles to Duilio it passes through a level country, and frequently...
expands into lakes. From Dufie to Lado (120 miles) the bed is contracted by rocky hills from a mile to a quarter of a mile in width; and the stream is forced over the Yarborah Rapids. At Lado (5° N. lat.) the river enters the plains, and moves thence slowly and sluggishly down to Khartoum, 900 miles to the north. The whole of this stretch is navigable for river-steamers of fairly large size. In 78° N. lat., however, the main channel divides; whilst the right arm, the Bahr-el-Zeraf, goes almost due north, but which still continues to be called the Bahr-el-Jebel, trends slightly to the west. Both streams flow, at no great distance apart, through a low swampy region, that is during the rainy season generally inundated for miles wide. The banks are lined with tall reeds and papyrus, the abode of numerous aquatic birds, and the shelter of swarms of gnats and other insect plagues. Since the year 1863 both these channels have been at times rendered wholly or in part impassable by vast accumulations of vegetable debris completely choking them. In 28° N. lat. the Bahr-el-Jebel is met by the Bahâl-Usazâ, which, coming directly from the west, gives the united stream, now called the White Nile, a due easterly course. Although this tributary, named the Usazâ, of 200 miles from the junction, runs nearly dry in the dry season, it gathers to itself the contributions of a very large number of rivers, some of them 300 and 400 miles long, which have their sources in the south and south-west in the country of the Niam-Niam tribes; one only, the Bahâl-Arab, comes from the northern side—Darfur, to the north-west.

Sixty miles east of the confluence the White Nile receives the Bahr-ul-Zeraf, and 30 miles farther east the navigable Sobat from the Gallu country. Some 60 miles down-stream from the Sobat mouth is Fashoda, whose occupation by Marjand in 1898 threatened to lead to war between France and England. From Fashoda the White Nile flows almost directly north to Khartoum without being augmented by a single tributary stream. At Khartoum (in 15° 37' N. lat.) the White Nile, or Bahr-el-Nil, as it is called, is joined from the south-east by the Blue Nile, the Bahâl-Azâk, the water of the respective streams being of the colour indicated in the names. The Blue Nile, 550 miles long, gathers its volume principally from Lake Tana (5683 feet above sea-level), situated on the Abyssinian plateau, in which region it is known as the Alat. It leaves the lake towards its southern end, and, after running south-east, curves right round by way of the south till it comes to flow north-west. After leaving the mountains it traverses an extremely fertile plain, the capital of which is Semnân. From Khartoum the Nile flows north-north-east, and 200 miles below that city is joined from the right by the Atbara, called also the Bahâl-Asâwâl, or Black Nile. It is the black sediment brought down by this river that gives the Nile delta, and makes it so extraordinarily fertile. It is the current, too, that gives its source on the Abyssinian plateau, and its volume is increased by two large tributaries, the Takazzé and Mareb, both striking into it from the right. During its course from the confluence of the Atbara through the Nubian Desert the great river makes three distinct turns round the north, then round by the south, and subsequently resumes its northerly flow. Below Khartoum navigation is rendered extremely dangerous by the cataracts which obstruct the bed of the river, the sixth occurring not far north of Khartoum, the first near Assuan, in Egypt, just above 24° N. lat. The course of the river from Assuan to the sea is sufficiently described under Egypt (q.v.), where also a map of the entire course is sketched. The total length of the river cannot be stated precisely; from Victoria Nyanza it is estimated to measure 4300 miles. The Nile begins to rise at Gondokoro in April, the Bahâl-Usazâ perhaps a week or two earlier. At Khartoum the rise begins in May, and reaches its maximum in September, whilst the Blue Nile rises from July to the third week in August (see NILEMETER). Irrigation is largely regulated by barrages at Rosetta and Damietta, constructed by French engineers in 1843-61, and practically reconstructed in 1886-90 at a cost of £405,000. A vast reservoir is to be made near Fihla (q.v.).

The ancients had little knowledge of the Nile above Meroc, between Berber and Khartoum. The place of accurate knowledge was taken by the Egyptians, with the result that the river is not a dangerous stream, after the passage of Khartoum and Assuan, and the great natural difficulties are confined to the first 400 miles below Khartoum, where the river is divided into a number of small channels. The cataracts obstruct the bed of the river, and render navigation extremely dangerous.
NIMES (Nîmes), the town of Aquitaine, is situated on a broad, level plain, about 80 miles south of the Seine. It is bounded on the north by the Rhône, and on the south by the Gardon. The city is built on a small hill, which rises abruptly from the plain, and is occasionally divided by radiating bands, in the form of a wheel; sometimes it takes a quatrefoil form. It is commonly of gold, but occasionally also in colours. The Glory is a combination of the nimbus and the aureole, and is chiefly seen in Byzantine pictures and those of the early South German school.

Nimeguen (Dutch Nijmegen), a town of Holland, in the province of Gelderland, on the left bank of the Waal, 73 miles by rail E. of Rotterdam. It is built on the slope of the Hoenderberg (‘Hill of the Huns’), on which the Romans formed the permanent camp of Noviomagus; and for her fame she is sometimes called the ‘vexilla piae,’ and is occasionally divided by radiating bands, in the form of a wheel; sometimes it takes a quatrefoil form. It is commonly of gold, but occasionally also in colours. The Glory is a combination of the nimbus and the aureole, and is chiefly seen in Byzantine pictures and those of the early South German school.

NILGIRI, the hill-range of south-west India, lies in the territory of Mysore, on the north-western border of Malwa, 370 miles SW. of Delhi by rail, 1015 feet above sea-level, with an agreeable and healthy climate. There has been a British cantonment here since 1817. Pop. of town, 5161; of cantonment, 13,069.

Nimbus, in Art, especially in Sacred Art, is the name given to the disc or halo which encircles the head of the sacred personage who is represented. It had a halo almost universal in those religions of which we possess a conventional form, the Egyptian, the Etruscan, the Greek, and the Roman. Some, indeed, have sought directly to derive it from the Greek μένζενθος, or metal disc placed over the heads of statues to keep off the drops of dew or dewdrops. It is strictly so called, is comparatively recent in Christian art, not appearing before the 6th century. Later in Christian art it became almost a necessary appendage of all representations of God or of the saints. Its ordinary form is the circular or semicircular mass of the nimbus of the Virgin is often in the form of a triangle, and that of the Trinity an emanation of light, the rays of which form the three arms of a cross. The nimbus of the Virgin is sometimes a simple ring, and sometimes a crown or diadem; occasionally it is encircled by an ornamental border, on which twelve stars are sometimes represented. Her nimbus, as well as that of the Divine Persons, is commonly of gold; but occasionally it is in colours, as blue, red, purple, or white. The nimbus of the saints is ordinarily the halos described above. In later art the nimbus became lighter and more aerial, melting, as it were, into the picture. In connection with the nimbus may also be mentioned the Aurorole, an illumination surrounding, not the head only, but the entire figure. If the figure be uplifted the aureole is commonly oval, when it is called the vexica piae, and is supposed to contain an allusion to the sacred Christian emblem, the Alpha and Omega. With a pointed figure it sometimes takes a quatrefoil form. It is commonly of gold, but occasionally also in colours. The Glory is a combination of the nimbus and the aureole, and is chiefly seen in Byzantine pictures and those of the early South German school.
NIMROD. See BABYLONIA, Vol. I. p. 633, also BABEL; or, un nom de plume, see AFTERLEY.

Nine Eyes, a popular name for the young lamppreys found in rivers. See LAMPPREY.

Nineveh, the modern Konyunjik, capital of the ancient kingdom of Assyria. Its original capital was Assur, the ruins of which are now called Kalâb Sharqat, but the greatest remains some sixty miles to the north, above the Greater Zab, and on the eastern side of the Tigris, namely Nineveh, Calah (Nimrud), and Dur-Sargun (Khorsabad), ultimately supplanted it in importance. When Nineveh itself fell, the whole Assyrian empire—originally a military polity—wasichael with it. In the 16th century the village was built on the mounds which covered its ruins; but when its buildings had also crumbled into ruins, the very site of the proud ancient city remained for centuries unknown. Rich in 1818 conjectured that the mounds Konyunjik, opposite the modern town of Mosul, concealed its ruins beneath, but it was not until the excavations of Botta in 1842 and Layard in 1845 that the remains, first of Dur-Sargun, then of Nineveh itself, were revealed to the world. The sculptured monuments of its ancient glory and relics of its stay-inscribed library soon yielded up their secrets to the investigations of scholars, and ere long the life and history of the ancient kingdom of Assyria were known almost with as much certainty as those of Greece and Rome. See ASSYRIA, and Cuneiform Inscriptions.

Ning-po, a treaty-port of the Chinese province of Che-kwang, stands in a fertile plain, 16 miles from the mouth of the Täkia (Ning-po) River and about 100 miles S. of Shanghai. It is surrounded by a wall 25 feet high and 16 feet thick, and contains numerous temples, colleges, &c., chief amongst them the temple of the Queen of Heaven figured under CHINA (Vol. III. p. 187); the temple was founded in the 12th century, but the present building, elaborately and richly ornamented, dates from 1690. The people, 250,000 in number, make saddle hats and mats, grow cotton, catch cuttle-fish, and carry on an active trade, especially in the export of green tea. The customs returns show the annual value of the imports—chiefly opium (30 per cent. of the total), cotton and woolen goods, tin and iron, medicines (in transit), dried lungaungas, kerosene oil, indigo, sugar, and tobacco—to be £1,250,000 (1886—1887). Of the exports—(70 per cent. of the total), cuttle-fish, saddle hats and mats, silk goods, and raw cotton—to be £1,259,300. Apart from junks, some 550 vessels, of 382,800 tons, enter every year, of which 128 vessels, with an aggregate of 127,900 tons, are British.

Ninian, St., the first known apostle of Scotland, was born of noble parentage, about 300, on the shores of the Solway Firth. Of studious and ascetic habits, he was moved by the Holy Spirit to make a pilgrimage to Rome and there, after some years' stay, was consecrated bishop by the pope. On his homeward way he visited St Martin (q.v.) at Tours, and after his arrival in Galloway he founded the "Candida Casa" or the Church of Whithorn dedicated to it to St Martin, the news of whose death had just reached him (397). Later he laboured successfully for the evangelisation of the Southern Picts, and in 432 (according to the Bollandists) died "effected in years" and was buried in his church at Whithorn. His festival falls on 10th September. His Life by St Alured (1109–66), abbot of Iona in Iona, who visited Galloway, has been edited by Bishop Forbes (vol. v., 'Historians of Scotland', series, 1874), who enumerates sixty-six dedications in Scotland to St Ninian or 'Rignon'—the Lowland Scotch form of his name—including the Episcopal cathedral at Perth.

Nios de Lenclos. See LENCLOS.

Niobe, in Greek Mythology, the daughter of Tantalus and wife of Amphion, king of Thebes, to whom she bore six sons and six daughters. Prou of her children, she despised Leto or Latona, who had only one child. As the goddesses themselves, upon Latona, enraged at her presumption, moved her children to destroy all the children of Niobe with their arrows. They lay nine days in their blood unburied, when Zeus changed them into stone, and on the tenth day they were buried by the gods themselves. Niobe was changed into stone on Mount Sipylos, in Lydia, from which tears flowed every summer. Such is the Homerid version, which, however, was afterwards much varied and enlarged. Only fragments exist of the tragedies of Aeschylus and Sophocles on this theme, which was a favourite subject of ancient art. A noble group representing Niobe and her children was discovered at Rome in 1583, and is now in the Uffizi Palace at Florence. Even the ancient Romans were in doubts whether the work proceeded from Socrates or Praxiteles. See HEYLDMANN, "Antiquitaten zu den Kunstwerken der Niobe" (Leip., 1853).

Niobium, Nb, equiv. 94) is a rare metal discovered by H. Rose in the mineral Tantalite. It may be obtained by passing the vapour of the chloride along with hydrogen through a red-hot tube. It is of a steel-grey colour, specific gravity 4.06, and takes fire when heated in the air or in chlorine gas. It is but little acted on by hydrochloric or nitric acid, but is soluble in strong sulphuric acid. It forms compounds with oxygen, chlorine, sulphur, &c., but these are of little practical importance.

Niort, the capital of the French department of Deux-Sèvres, pleasantly situated on the navigable Sèvre Niortaise, 43 miles N.E. of La Rochelle and 100 S.W. of Tours. An important railway junction, it has an old castle, a hôtel-de-ville (1530), a fine public garden, and the 16th-century church of Notre Dame, with a spire 246 feet high. The dressing of leather and the manufacture of gloves are the leading industries. Pop. (1872) 29,622; (1891) 29,901. A port in the 14th century was held for eighteen years by the English. It was the birthplace of Madame de Maintenon. See Favre's "Histoire de Niort" (1880).

Nipigon, a lake of Ontario, 30 miles N.W. of Lake Superior, with which it is connected by the Nipigon River. It is about 70 miles long, but its deeply-indented coast-line measures 580 miles. Its greatest depth is 510 feet. The lake is studded with hundreds of islands.

Nipissing, a lake of Ontario, north-east of Lake Huron, into which (Georgian Bay) it drains through French River (55 miles). Its length is about 50 by 28 miles.

Nipples. See BREAST.

Nippon. See Japan.

Nisch, the chief town and commercial centre of southern Servia, stands in the midst of a vine-growing district, 125 miles by rail SE. of Belgrade. It is the seat of a Greek Bishop and has a fairly strong citadel (1737). The place has played a conspicuous part in the Turkish wars from 1735 down to 1878, when it was occupied by Servia. Here, on 23rd September 1689, the Austrarians defeated the Turks. Pop. (1854) 16,178.

Nishapur, a town of the Persian province of Khurasan, 63 miles W. of Meshed, in a beautiful and fertile valley, has 11,000 inhabitants and a
trade in turquoises. It was the birthplace, and contains the grave, of Omar Khayyam.

Nisibis, the capital of ancient Mygdonia, the north-eastern part of Mesopotamia, was a city of great antiquity, and was of importance both as a place of strength and as an emporium of the trade between the Indian and Parthian empires. It was taken by the Romans (under Lucullus and Trajan), and again given up by them to the Armenians; but being a third time taken, in 105 A.D., it remained the chief bulwark of the Roman empire against the Persians, till it was surrendered to them after the death of Trajan. The town of Nisibis is re-tained by a small village in the Turkish province of Diarbekir, round which are numerous remains of the ancient city.

Nisi prius is the name (borrowed from the first two words of the old writ which summoned juries) usually given in England to the sittings of juries in civil cases. Thus, a judge sitting at nisi prius means a judge presiding at a jury trial in a civil cause, and a nisi prius lawyer is one who devotes himself to jury practice.—For the decree nisi, see DIVORCE.

Nith, a beautiful Scottish river, rising in Ayrshire, and flowing 71 miles south-south-eastward (mainly through Dumfriesshire), to which is below Dumfries, its estuary joins the Solway Firth.

Nithsdale, William Maxwell, Earl of, was born in 1676, and at seven succeeded his father as fifth earl. In 1699 he married at Paris Lady Winifred Herbert (c.1679-1749), youngest daughter of the Marquis of Powis, and thenceforward lived almost constantly at his Kirkenuighshire seat, Terregles, much embarrassed in circumstances, and sorely troubled as a Catholic by the neighbouring Presbyterian ministers. In 1715 'Nithsdale's bonnie lord' at once joined the English Jacobites under Forster and Derwentwater, and was taken prisoner at Preston. He was tried for high treason in London, and sentenced to death in spite of abject excuses; but on 23rd February 1716—the night before the day fixed for his execution—not knowing he had just been reprieved, he escaped from the Tower in woman's apparel, through the heroism of his countess, warmly detailed and then advanced in pregnancy, she had ridden up to London in the depth of winter; and after her lord's escape she came back to Terregles, and dug up the family deeds, which she had buried in the garden, and by one of which the estates had been disposed in 1712 to their only son. They now settled at Irvine, where the earl died on 20th March 1744. See Sir W. Fraser's Book of Carlukeirook (2 vols. 1873).

Nitrates. See Nitre, Nitric Acid, Nitration, Manure.

Nitre, or Saltpetre (Lat. sal petre, 'salt of the rock') through Old French), is the nitrate of potash, KNO₃. It usually occurs in long, colourless, striated, six-sided prisms; its taste is cooling, and very soluble; it is soluble 10 times its weight of water at 60° (15.5° C.), and in less than one-third of its weight of boiling water, but is insoluble in alcohol. When heated to about 660° (345° C.) it fuses without decomposition into a thin liquid, which is inflammable. In mounds, solidifies into a white, fibrous, translucent mass, sometimes known as nitre prunelle. At a higher temperature part of the oxygen is evolved, and nitrate of potash is formed. Owing to the facility with which nitre parts with its oxygen, it is much employed as an oxidising agent. Mixtures of nitre and strong acid, of nitre and sulphur, or of nitre, carbon, and sulphur, deglaze on the application of heat with great energy; and if nitre be thrown on glowing coals it produces a brisk scintillation. Touch-paper is formed by dipping paper in a solution of nitre, and driving it.

Nitre occurs as a natural product in India and Persia, where it is found sometimes as an efflorescence on the soil, and sometimes disseminated through its upper stratum. The crude salt is obtained by lixiviating the soil, and allowing the solution to crystallise. Much nitre used to be artificially formed in Europe by imitating the conditions under which it is naturally produced. The animal nitre (as dung ashes and lime rubbish, is placed in loosely aggregated heaps, exposed to the air, but sheltered from rain. The heaps are watered from time to time with urine or stable runnings; at suitable intervals the earth is lixiviated, and the salt crystallised. As there is always a considerable quantity of the nitrates of lime and magnesia present, which will not crystallise, carbonate of potash, in the shape of woodashes, is added so long as any precipitate occurs. The nitrate of lime is decomposed, and the insoluble carbonate of lime separated. The clear liquor is then evaporated and crystallised. But the oil of the nitre of commerce is now made from the Chilian nitrate of soda by double decomposition. The common varieties of Indian nitre, which have a dirty yellowish appearance, are termed rough or crude salpetre, while the purer kinds are called East India saltpetre. The materials from which nitre is obtained by lixiviation is effectuated by dissolving it in water, boiling the solution, removing the scum, straining it while hot, and setting it aside to crystallise. The most common impurities are sulphate of potash, chlorides of sodium and potassium, and nitrate of lime. Chloride of baryta will remove these impurities, nitrate of silver the second, and oxalate of ammonia the third.

Nitre is employed in the manufacture of sulphuric acid, in the preparation of nitric acid, as an oxidising agent in numerous chemical processes, as an ingredient of fireworks, and especially in the manufacture of gunpowder. It is used in medicine. In moderate doses (from ten grains to a scruple) it acts as a refrigerant, diuretic, and diaphoretic, and hence its use is indicated when we wish to diminish the abnormal heat of the body, or reduce the pulse, as in febrile disorders and hemorrhages. In acute rheumatism it is given in large doses with great benefit. It is a popular remedy in sore throat, in the form of nitre balls, which should be retained in the mouth till it melts, and the saliva is impregnated with it, gently swallowed. The inhalation of the fumes produced by the ignition of touch-paper often gives speedy relief in cases of spasmodic asthma.

Cubic Nitre, or Nitrate of Soda, NaN₃Oₗ, occurs abundantly on the surface of the soil in Chili and Peru (especially Atnaca and Tarapacá). It derives its name from its crystallising in cube-like rhombohedrons. In most of its properties it resembles ordinary nitre, but, in consequence of its greater deliquescentesce, it cannot be substituted for that salt in the preparation of gunpowder. Being considerably cheaper than the pure salt, cubic nitre is often substituted for it in the manufacture of nitric and sulphuric acids; and it is largely used in agriculture (see MANURE). In 1882 the amount shipped from South American ports was estimated at 170,000 tons. A. W. H. Russell's Visit to Chili and the Nitrate Fields of Tarapacá (1890). For the Sweet Spirits of Nitre, see NITROUS ETHER.

Nitrin Desert. See NATRON LAKES.

Nitric Acid is the most important of the five compounds which oxygen forms with Nitrogen (q.v.). Until 1849 it was known only in the hydrated form (the aquafortis of the older chemists),
but in that year Deville showed that Anhydrous Nitric Acid, or Anhydride, NO₂ (see Nitrogen), might be obtained in transparent colourless crystals by the action of perfectly dry chlorine gas on well-dried crystals of nitrate of silver, the reaction being exhibited in the equation:

\[ \text{Nitrates of Silver, Chlorine, Chlorate at Silver. Nitric Anhydride. Oxygen.} \]

\[ 2\text{AgNO}_3 + \text{Cl}_2 = 2\text{AgCl} + \text{NO}_2 + \text{O}_2 \]

It is a very unstable compound, and sometimes explodes spontaneously. It dissolves in water with evolution of much heat, and forms hydrated nitric acid. Nitric Acid (sym. HNO₃; equiv. 63; sp. gr. 1.530), when perfectly pure, is a colourless, limpid, fuming, powerful caustic fluid, possessing an intensely acid reaction, as shown by its action on litmus. It boils at 187° (36°C). It burns readily with a portion of its oxygen to most metals, and hence is used in the laboratory as an oxidising agent. Whether in the concentrated or in a more dilute form, it acts energetically on organic matters. As examples of such actions we may refer to its power of decolourising indigo; in stagnant water it produces a bright-yellow colour; of coagulating fluid albumen; and of converting cotton fibre into an explosive substance (see Gun-Cotton). The applications of this acid in the arts, in manufactures, and in chemical processes are very extensive. The so-called Concentrated Acid, HNO₃, is by no means a stable compound. If it be exposed to the action of light it is decomposed with the formation of lower oxides of nitrogen; and mere distillation produces a similar effect. When it is mixed with water it emits a sensible amount of heat, owing to the formation of a more stable hydrate, 2HNO₃ + 3H₂O, which distils at 250° (121°C) without change, and is unaffected by exposure to light. Its specific gravity is 1.424; and it is found that a weaker acid than the former, more suitable for all the purposes of science, is obtained by adding nitric acid to water in the proportion of 1:100. The addition of a small quantity of the liquid becomes reddish brown or purple; the dark colour being due to the formation of nitric oxide by the oxidising action of a portion of the iron salt on the nitric acid.

Medicinal Uses. In the British pharmacopoeia there is both a strong and a dilute acid. The strong acid has a specific gravity of 1.42, contains 70 per cent. of real acid, HNO₃, while the diluted acid is prepared by mixing six ounces of the former with about twenty-five of distilled water, and has a specific gravity of 1.101. The dilute acid is used internally as a tonic in conjunction with bitter infusions. In many cases of biliousness, of chronic inflammation of the liver, and in syphilitic cases in which mercurials are inadmissible, it may be prescribed with beneficial effect, or in conjunction with hydrochloric acid, externally as a salve or lotion, or internally in doses of about 20 minims properly diluted. The strong acid is useful as an escharotic; e.g. to destroy warts, some kinds of polypi, the unhealthy tissue in sloughing ulcers, &c., and in the general alleviation of morbid ulceration. Largely diluted—as 50 or 60 drops of the strong acid to a pint or more of water—it forms a stimulative application for torpid ulcers.

Nitrification is the changing of nitrogenous organic matter or ammonium compounds into nitrates. Possibly the nitrogen of the air under certain circumstances is so soluble that no precipitant for this acid is known. The best method for its detection is mixing the fluid to be tested with a solution of sulphate of iron, and then carefully pouring sulphuric acid through a tube to the bottom of the glass so as to form a lower oxide of nitrogen. If the acid is properly concentrated a black colour is produced; if only a small quantity is present the liquid becomes reddish brown or purple; the dark colour being due to the formation of nitric oxide by the oxidising action of a portion of the iron salt on the nitric acid.
Nitrogen

Nitrogen to that pointing is the so was very air South obtained discover It cer-play or water, not the micro-organisms 1772 and and its presence, is nitrogenous compounds in the soil through the influence of micro-organisms present there. Another explanation attributes the fixation of nitrogen by micro-organisms existing in, or on the surface of, the plant. On the other hand, it has been conclusively shown that certain plants are unable to exist unless appropriate compounds of nitrogen are supplied to them in the soil in which they grow. The main supply of the nitrogen of plants is certainly drawn from nitrogen compounds existing in or artificially supplied to the soil. The most important of such nitrogen compounds are nitrates, which are present in every fertile soil. These may be produced by the decay in the soil of nitrogenous animal or vegetable matters, or they may be added to it ready formed—as, for instance, in the form of sodium nitrate, which is frequently applied as a manure to soils poor in nitrates.

Many attempts have been made to discover methods by which the nitrogen of the atmosphere could be converted or a manufacturing scale into nitrogen compounds, but as yet no workable and economical method has been discovered. There are numerous methods for preparing pure or nearly pure nitrogen. One method by which it is obtained very nearly pure is to remove the oxygen as completely as possible from atmospheric air. This can best be done by passing a current of air slowly through a red-hot tube packed with copper turnings or with spirals of copper wire gauge. The oxygen of the air combines with the copper to form an oxide of copper, whilst the nitrogen passes on. Or the oxygen can be very completely removed from a confined portion of moist air by suspending in it pieces of phosphorus until the volume of the gas ceases to diminish. Nitrogen can also be prepared by passing an electric current of chlorine gas into a solution of ammonia. In this method care must be taken always to use ammonia in excess, otherwise chlorine of nitrogen would be produced, which is a dangerously explosive substance. A steady current of nitrogen can be very easily obtained by heating together strong solutions of ammonium chloride and of potassium nitrate. Owing to the great difficulty of forming compounds from free nitrogen, new compounds of nitrogen are generally prepared from compounds already existing. The most important of these compounds, which are found in the soil in very considerable quantity in different parts of the world, and in some places occur in large deposits, as in the nitrate regions of South America. From these nitrates Nitric Acid (q.v.) and other compounds of nitrogen are prepared. Many important chemical compounds of nitrogen with oxygen are known.

Nitrous Oxide, or laughing-gas, N₂O, was discovered in 1772 by Priestley, who obtained it by the action on nitric oxide of easily oxidizable substances. It is now prepared by the action of heat on ammonium nitrate:

\[ \text{NH}_4\text{NO}_3 = \text{N}_2 + 2\text{H}_2\text{O} \]

It is a colourless gas, which can with moderate ease be reduced to the liquid state, a pressure of thirty
Porosity substance, is thereby rendered safe from the dangers incident to the employment of nitro-glycerine without such treatment. Nitro-glycerine, as manufactured on a large scale for commercial purposes, is obtained by the nitration of silver nitrate and sulphuric acids, cooled by water, previous to being introduced into a large leaden vessel, the temperature of which is kept down by water circulating through coils inside. Glycerine is then injected by compressed air as a fine spray, and becomes immediately nitro-glycerine. A considerable heat is being evolved. On the completion of the nitration, as indicated by the fall of temperature, the mixture is run off into another leaden vessel and allowed to stand. In about an hour the separation is complete. The nitro-glycerine, after being thoroughly washed in water and subsequently heated to an alkaline solution to remove every trace of acid, is ready for manufacture into dynamite or other nitro-glycerine compounds. The utmost care is exercised in the above processes, and any abnormal rise in temperature is immediately stopped. For similar reasons the materials employed in the manufacture of nitro-glycerine are in every particular the best and purest attainable. Colourless when pure, but having as an article of commerce a pale brown colour, nitro-glycerine is a dense, oily liquid, of a pungent, aromatic, inodorous, but has a sweet, pungent, aromatic taste; a single drop, however, if placed on the back of the tongue, will produce headache and pain in the back lasting for hours. By those accustomed to handling this substance, no inconvenience whatever is experienced. Nitro-glycerine enters into medical prescriptions for certain diseases of the heart.

If ignited in the open air nitro-glycerine burns rapidly and with a brisk flame without any explosion; and if poured out in a thin sheet it ignites with difficulty and burns incompletely; but it explodes at once if it is exposed to a moderately strong blast or concussion, to the concussion due to the explosion of gunpowder, to contact with red-hot iron, and especially to the action of detonating mixtures and fulminates. It likewise explodes when thrown into a magazine with other nitro-glycerine compounds, phials, or similar articles. See also ASSOCIATED BODIES.

Nitro-glycerine (known also as Glicerina or Glicerine-oil) can be readily prepared by dissolving glycerine in equal measures of strong nitric and sulphuric acids and pouring the solution into water, when the nitro-glycerine becomes precipitated. Nitro-glycerine was discovered by Sobrero, a young Italian chemist at Paris, who in 1846 found that by the above process he could produce a highly explosive mixture. There was little idea at the time of the value of the discovery, which was treated solely as a chemical curiosity, until about fifteen years later, when Alfred Nobel, a Swedish engineer and chemist, perceiving the value of the unreconised explosive and turning his attention to its development, rapidly introduced it as a blasting agent for industrial purposes. The new explosive was sufficiently satisfactory so far as blasting power was concerned, but a series of fearful accidents, notably that to the ship Europe on the Panama at Panama in 1866—numerous expedients devised to render it safe in transit notwithstanding—called public attention to the danger inseparable from its use. Its safety, and in 1868 parliament, so far as Britain was concerned, placed its veto on nitro-glycerine.

The drawbacks which culminated in this prohibition led to the production of the nitro-glycerine compounds, now forming a large group, notably dynamite (see DYNAMITE, Vol. IV, p. 144), in which nitro-glycerine, absorbed by some inert atmospheres being required to liquefy it at 0° C. Davy discovered in 1809 that it possessed anesthetic properties, and it is now used as an anesthetic in minor surgical operations. For such purposes it is obtained in the liquid state by dentists and others in wrought-iron bottles. It is a supporter of combustion, and burning materials placed in it continue to burn with almost as great brilliancy as if placed in free oxygen. Nitric Oxide, NO, is produced by the action of nitric acid on carbon, silver, or mercury. It is a colourless gas, which like nitrogen only can be reduced to the liquid state by pressure after it has been cooled to a very low temperature. Its most striking character is the great readiness with which it mixes with free oxygen, forming dense brown fumes, which consist mainly of peroxide of nitrogen.

Nitrous Anhydride has been described as a gas easily condensable to a liquid, possessing the composition represented by the formula N₂O₄. It seems very questionable whether a single substance of the state of mass of liquid, possessing this composition. The gas which was supposed to be nitrous anhydride was certainly a mixture. Although nitrous anhydride cannot be obtained pure, and the corresponding acid—nitrous acid—is an unstable substance at ordinary temperatures, in unities, salts corresponding to nitrous acid, are known. Peroxide of Nitrogen, NO₂ or N₂O₅, is produced when oxygen and nitric oxide are mixed. It is a dark-brown liquid at ordinary temperatures, which boils at 22°, yielding a brown vapour, and solidifies at -9°, forming colourless crystals.

Nitric Anhydride, N₂O₅, is the anhydride of nitric acid, and can be obtained amongst other ways from nitric acid by the action on it of phosphoric anhydride (see NICRIC ACID).

The following are some of the other important nitrogen compounds: ammonia and the ammonium salts (see AMMONIA); the alkaloids (see ALKALOIDS); aniline and its derivatives; cyanogen and the cyanides, including hydrocyanic acid; albumenoid substances; urea and uric acid; nitro-benzene, and other nitro compounds; pyridines and quinolines; nitroso compounds, phials, and similar articles. See also ASSOCIATED BODIES.

Nitrous Ether, or Nitrite of Ethyl, C₂H₅NO₂, is a very volatile ether, with an agree-
able apple odor, and having a specific gravity of 0.900. It boils at 64°-18° C., and is highly inflammable. It is readily soluble in alcohol and glycerine, less so in water. Acetic acid is liable to decomposition when kept with the acetic acid on keeping. It may be prepared by the action of sulphuric acid and alcohol on nitrate of potash. In itself it is of little importance, but on account of its relation to the sweet spirits of nitre or spirit of nitrous ether is one of the most important drugs. It was for long thought that the virtues of this valuable remedy were proportionally due to the nitrous ether present, and attention was directed to the preparation of the pure Substance. When this was administered in the form of solution of the strength of sweet spirits of nitre, it was found that its action was different from and inferior to that of the latter. The sweet spirits of nitre contains in addition aldehyde and paraldehyde, and it is believed that these we must ascribe much of its virtue. Be this as it may, the legal test is based on the presence of some ethereal body, presumably nitrite of ethyl, and yet many a sample may be efficacious and fail to satisfy the standard test. The spirit should be freshly made, be kept in well-closed bottles, and should not be aged. Its specific gravity should not exceed 0.915, as an admixture of water deteriorates it. It may be prepared by the action of nitric and sulphuric acids on alcohol in the presence of copper, but manufacturers attain the same end by other processes. It is used, in conjunction with other medicines, as a diuretic, especially in the dropsy, to which fellow sufferer it is employed, in combination with acetate of ammonia and tartarised antimony, in febrile affections. The dose in febrile cases is from half a dram to a couple of drachms; while for a diuretic two or three drachms should be given.

Nitrous Oxide. See Nitrogen.

Nitzsch, Karl Ludwig, a Protestant theologian, was born 6th August 1751 at Wittenberg, laboured as pastor and superintendent, became in 1790 a professor at Wittenberg, and in 1813 director of the seminary for preachers there. Here he died, 5th December 1831. He wrote two works on revelation. —Karl Immanuel Nitzsch, his son, was born at Borna, in Saxony, 21st September 1757, studied at Wittenberg, preached in Meissen and obeyed a call to Halle in 1822. Here he laboured assiduously till 1847, when he went to Berlin as successor to Marheineke, as well as university preacher and consistorial councillor. Here he died, 21st August 1858. Nitzsch was the most prominent supporter of the Union (see Lutherans), and in theology he was an independent supporter of Schleiermacher's opinions. He subordinated dogma to ethics, and was one of the leaders of the 'Vermittlungs-Theologie'—the broad evangelical school. Of his books the chief are System der Christlichen Lehre (2nd Eng. trans., 1849), Praktische Theologie (3 vols. 1847-87), Akademische Vorträge über Christliche Glaubenslehre (1838), several volumes of sermons, and Gesammelte Abhandlungen (2 vols. 1850). See the studies by Reischlag (2d ed. Halle, 1882) and Hermeus (Hamburg, 1886).—Gregor Wilhelm Nitzsch, his brother, a brotherhood was born at Wittenberg, 22nd November 1790. He studied in his native town, fought as a volunteer at Leipzig, became in 1827 professor at Kiel, in 1829 at Leipzig, and died there, 22nd July 1861. His studies were mainly devoted to the Homer. His own poetry, and the 511

R. M. —Karl Wilhelm Nitzsch, son of the preceding, was born at Zerbst, 22nd December 1818, studied at Kiel and Berlin, was 1844 extraordinary, in 1853 ordinary professor at Kiel, in 1862 at Königsberg, in 1872 at Berlin, and died 20th June 1880. His writings embrace historical studies on Polybius (1842) and the Gracchi (1847), Die Römische Annalenistik (1873), Deutsche Studien (1879) as well as the posthumous history of the German people to the peace of Augsburg, edited by Matthi (3 vols. 1883-85), and a history of the Roman Republic, edited by Thouret (2 vols. 1854-85).—Friedrich August Berthold Nitzsch, theologian, son of Karl humanist, was born at Borna, 19th February 1822, studied at Berlin, Halle, and Bonn, and became in 1868 professor of Theology at Giessen, in 1872 at Kiel. His writings include Das System des Boethius (1860), Grundriss der Christlichen Dogmengeschichte (1879), Luther und Ariadnetes (1883).

Nivelles (Flém. Népet), a town in the Belgian province of Brabant, on the Thines, 16 miles by rail S. of Brussels. Its fine Romanesque church (1045) contains the relics of Pepin's daughter, St. Gertrude. In 1381 the townfolk of Ghent were defeated here by Count Louis of Flanders, and 6000 burnt in a monastery. Nivelles has manufactures of cotton, linen, and lace, and presents a picturesque appearance, but the principal inducements are the counts, afterwards dukes, of Nevers, who held under their vassalage more than 1800 towns.

Nouilles, a distinguished French family which dates from the 11th century, and played an important part in history from the reign of Louis XIV. to the Revolution. Antoine (1504-62) was ambassador in England in 1553-66, and ambassador to France. His son, Louis (1560-1708), son of the first duke, commanded against the Huguenots and in Spain during the war of the Spanish succession, and was made marshal; whilst his brother, Louis Antoine (1651-1729), was Archbishop of Paris from 1696 till his death, and was created duc de la Marche. The third duke, Adrien Maurice (1673-1706), won the marshal's baton in the wars of Louis XV. in Spain, Italy, and Germany. The fifth duke, Paul François (1739-1824), attained eminence as a chemist and was elected to the Academy of Sciences in 1777; his brother, Emmanuel Marie Louis (1743-1822), was French ambassador at Amsterdam (1770-76), London (1776-83), and Vienna (1783-92). The sixth duke, Paul (1802-85), wrote historical works, and was elected to Chateaubriand's chair in the Academy in 1849. His second son, Emmanuel Victor (born 1830), was an ambassador at Washington (1872), Rome (1873), and Constantinople (1882-86), and has written works on the history and literature of Poland. A grandson of the third duke, Louis Marie (1756-1864), served in America under his brother and came to England during the French Revolution, and defended San Domingo against the British.

Noble Office. The term used in the law of Scotland to denote the high prerogative right of the Court of Session to exercise jurisdiction in certain cases—as, for example, to appoint a judicial factor to young children or to lunatics.

Nobility, that distinction of rank in civil society which raises a man above the condition of
the mass of the people. Society has a tendency to inequity of condition, arising from the natural inequality, physical, moral, and intellectual, of those who compose it, aided by the diversity of external advantages, and of the principles and laws of a country. The feudal system, with its feudal ranks, and the accompanying feudal rights which are given to him which is apt to increase; the son inheriting the faculties of his father is more favourably situated than his father was for making use of them; and hence in every almost nation in even the very early stages of civilisation we find something like a hereditary nobility. Dying or becoming extinct, it is redborn by new encroachments of the people. In a country where personal or political power are secured to the family of the possessor of a coat-of-arms, and the privileged class that constitutes an order, admission into which requires the consent of society or of the order itself. The ancient Romans were divided into nobles and ignobles, a distinction at first corresponding to that of patricians and plebeians. A new nobility afterwards sprung out of the plebeian order, and obtained (336 B.C.) the right to rise to high offices in the state; and in course of time the descendents of those who had filled curule magistracies inherited the power. The right bequeathed to their ancestors—a privilege which, like the coat-of-arms in later ages, was considered the criterion of nobility. The man entitled to his own image was a homo nobile, while the ignobilis could neither have his ancestor's image nor his own.

Throughout the middle ages the lesser nobility of England and continental Europe is in part connected with the accidents which influenced the division of conquered lands among the leaders and warriors of the nations that overthrew the Roman empire, and is sketched in the article Feudalism (q.v.); and the evolution of the dignities of Baron, Count (C. Tit.), Earl, Marquis, Duke, and other ranks will be found under those several heads. In the subinfeudations of the greater nobility originated a secondary sort of nobility, under the name of Vavasours, Castellans, and lesser barons; and a third order below them comprised vassals, whose tenure, by the military obligation known in England as knight's service, admitted them within the ranks of the aristocracy. In France the allegiance of the lesser nobles to their immediate lord long continued a reality; in England, on the other hand, William the Conqueror with his Norman line kept the chief of the crown, but their vassals also, to take an oath of fealty to himself; and his successors altogether abolished subinfeudation. The military tenant, who held but a portion of a knight's fee, participated in all the privileges of nobility, and an impassable barrier existed between his order and the common people. Over continental Europe in general the nobles, greater and lesser, were in use, after the 10th century, to assume a territorial name from their castles or the principal town or village on their demesne; hence the prefix 'de,' or in the case of Castilis, Earl, Marquis, Duke, and other ranks will be found under those several heads.

The higher nobility, or nobility in the exclusive sense, of England consists of the five territorial ranks of the peerage—Duke, Marquis, Earl, Viscount, and Baron (in the United Kingdom); and the members of the House of Lords who are members of the Upper House of Parliament. Archbishops and bishops are lords temporal, but not peers. The dignity of the peerage is hereditary, but in early times was territorial, the dignity originally being attached to the possession of the land, and held during the return for services to be performed to the sovereign. Later, peers were created by writ of summons to attend the king's council or parliament, but now the creation of a new peer is always made by letters-patent from the crown. In order to the efficient carrying out of the appellate jurisdiction of the House of Lords there are now a limited number of life peers, styled Lords of Appeal in Ordinary. By the Appellate Jurisdiction Act, 1876, as amended 1887, it is enacted that every such lord, unless he is otherwise entitled to sit in the House of Lords, shall by virtue and according to the date of his appointment be entitled during his life to rank as a baron, and shall be entitled to a writ of summons to attend and to sit and vote in the House of Lords. But his dignity is not to descend to his heirs. A peerage is forfeited by attainder for high treason, and on conviction of high treason by writ, not by patent; on attainder, peerage cannot be restored by the crown, only by an act of parliament. Ladies may be peeresses in their own right either by creation or by inheritance. The wives of peers are also styled peeresses. The question as to descent through males only or through females will be found noted.

The first example of the feudal aristocracy to the crown always was, and continued to be a reality, the resistance of the nobles to the royal encroachments was the means of rearing the great fabric of constitutional liberty. All those who, after the Conquest, held in capite from William belonged to the nobility. Such of them as held by subinfeudation (see above) are enumerated in Domesday. Their dignity was territorial, not personal, having no existence apart from baronial possession. The come was a baron of superior dignity and greater estates; and these were in England the only names of dignity till the time of Henry II. (that, and not the come of arms) was the title most prevalent.

After the introduction of Heraldry (q.v.), and its reduction to a system, the possession of a coat-of-arms was a recognised distinction between the noble and the plebeian. On the Continent whoever has a shield of arms is a nobleman; and in every country of continental Europe a grant of arms, or letters of nobility, is conferred on all such a noble's descendants. In England, on the other hand, the words noble and nobility are restricted to the five ranks of the peerage constituting the greater nobility, and to the head of the family, to whom all the minors of the same rank and of the same family are appurtenant (see Gentleman). Thus a difference of usage is a frequent source of misapprehension on both sides of the Channel; at some of the minor German courts the title of member of an English noble family, like a coat-of-arms, is the possession of blood and lineage has sometimes been postponed to a recently-created baron or 'Herr von,' who has received that title, and the gentility accompanying it, along with his commission in the army. It has been taken for granted that the latter belongs to the 'Adel,' and is not the name of a class, as the term 'noble' in England, or the more strict sense, corresponds to the nobility of continental countries (see Gentleman).
the articles on the several orders of nobility. The
older English parliaments is the earlond of Arundel,
dating from 1155, and now held by the Dukes of
Norfolk; the Irish barony of Kingsdale dates from
1181; to the period 1181-1205 belong four baronies
now merged in other titles; the Scottish earlond of
Sutherland goes back to 1229; and the baronies of
Dundonald, De Ros, and Hastings are all of the year
1234.
By the Act of Union between England and
Scotland the Scotch peers elect sixteen of their
capacity to sit in the House of Lords in each
parliament. The peers of Ireland, in
victuarial times (so recently as 1811) only
an average of twenty-eight of their number to sit in the House of Lords for
time. The Act of Union with Scotland has been
understood to debar the sovereign from creating any
new Scotch peerages; all peers created in either
England or Scotland between that date and the
union with Ireland are peers of Great Britain; and
peers created in any of the three kingdoms
subsequently to the union with Ireland are peers of
the United Kingdom, with this exception that one
new peerage of Ireland may be created on the
expiration of any Irish barony. When generation
Irish peers are reduced to one hundred, then on the
extinction of onepeerage another may be created.
All peers of Great Britain or of the United
Kingdom have a seat in the House of Lords. A Scotch
peer, though not one of the sixteen representative
persons in the House of Commons, the House of
peerage, a disability which does not attach to
Irish peers. The peerage has from time to
time recruited by new additions, the persons selected
being in general peers of Scotland or Ireland;
younger members of the families of peers; royal
ladies (so recently as 1811) were occasionally
beholding for military, political, or diplomatic services;
eminent lawyers promoted to high judicial
appointments; persons of large property and ancient
family, noble in the more extended sense; and
lastly, persons who by commerce acquired large
fortunes and social importance. Many of the
Scottish and Irish peers sit in the House of Lords as
peers either of England, Great Britain, or of the
United Kingdom. The privileges belonging to
peers as members of parliament will be explained
under the more general head of nobility, but they also possess the
following immunities: they can only be tried
by their peers for felony, treason, or misprision of
treason, when the whole members of the
peerage are summoned. All the privileges belonging to the
English peerage, except the right of sitting in the
House of Lords, were extended to the peers of
Scotland by the Treaty of Union. A peer who has
different titles in the peerage takes in ordinary
parlance his highest title, one of the inferior titles
being given by courtesy to his eldest son. Certain
Viscount Titles (q.v.) belong also to the daughters
and younger sons of a peer, but do not extend to
their children. British subjects can hold foreign
titles of nobility only by consent of the crown.
The ancient Scottish barony of Fairfax has since
1890 been confirmed to citizens of the United
States of America in Virginia. The sixteenth
was a friend of Washington, the tenth (1829-69)
spoke of the California House of Representa-
tives. The barons of Longueuil, a Canadian
family, are recognised in Britain (see Le MOYNE).
In 1390 a limited body of the higher nobility,
styled the peers, were in the enjoyment of privileges
not possessed by the rest. The title of Duke was
subject to strict rule, but many titles of Marquis
and Count, believed to be pure assumptions, were
recognised by the courtesy of society. The head of a
family of peers was styled the Earl, and these were
the title of marquis; and if an estate was purchased
which had belonged to a titled family the purchaser
was in the habit of transferring to himself the
honours possessed by his predecessors a practice
which Louis XV. put a stop. Immediately before
the Revolution 80,000 families claimed nobility,
many of them of obscure station, and less than 3000
of ancient lineage. Nobles and clergy together
possessed two-thirds of the land. Practically, the
qualification of being a member of a family was
held to depend not so much on the degree of his
title as on its antiquity, and the distinction of those
who had borne it. The higher titles of nobility
were not borne by all members of a family; each
son assumed a title from one of the family estates.
The extinction of one member was no bar to
'roturier' lands, which divided among all the
children equally, noble fiefs went to the eldest son.
The Revolution overthrew all distinction of ranks.
On 18th June 1790 the National Assembly decreed
that hereditary nobility was an institution incom-
patible with a free state, and those titles, arms, and
livestock should be abolished. Two years later the
records of the nobility were burned. A new
nobility was created by the Emperor Napoleon I.
in 1808, with titles descending to the eldest son.
The Old nobility was thus completely extin-
tion. All marquises and viscounts are of pre-
revolution titles, none having been created in later
times.
Commercial pursuits have more or less in
different countries been considered incompatible
with nobility. In the United States, as in France and
Germany, where for long a gentleman could not engage in any trade without
losing his rank. A sort of commercial 'Bürger-
adel,' or half-gentleman class, was constituted out
of the patrician families of some of the great
German cities, notably Ansbach, Bamberg, and
Frankfort, on whom the emperors bestowed
coats-of-arms. In semi-feudal Italy there was on
the whole less antagonism between nobility and
trade than in France and Germany. The aristocracy of
Venice had its origin in commerce; and, though
untitled, they were among the most distinguished
class of nobles in Europe. On the other hand, in
Florence, in the 14th century, under a constitution
purely mercantile, nobility became a disqualification
from holding any office of the state. In order
to the enjoyment of this possession, a nobleman
be struck off the rolls of nobility; and an
unpopular plebeian was sometimes ennobled in order
to disfranchise him. A little later there grew up,
side by side with the old nobility, a race of plebeian
nobles—as the Medici—whose pretensions were
originally derived from wealth, and who eventually
came to be regarded as aristocrats by the democ-

cratic party.
The nobility of Spain boasts of a special
antiquity and purity of blood, a descent from
warriors and conquerors alone. 'Hidalgo' (q.v.) is a
term which signifies gentility or nobility; the
Hidalgo alone has in strictness a right to the
title 'Don,' which has latterly been used by persons
who have no proper claim to it about as extensively
as 'Esquire' in England. The higher nobility are
the titled Grandees (q.v.); the class of nobility below
them are called 'Titulares.' Red blood is said to
flow in the veins of the hidalgo, blnc in that of
the grandee. The preservation of noble blood, un-
contaminated by plebeian intermixture, has often been
reckoned a matter of much moment. The Span-
iards have no middle classes; all are either in the
empire no successor was allowed to take up
without the immediate of the emperor,
unless both parents belonged to the higher nobility.
In France the offspring of a gentleman by a
plebeian mother was, to a large extent, deprived of exemption from tribute, but could not be received
into any order of chivalry. Letters of nobility were
sometimes granted to relaisate persons in this position. In Norway titular hereditary nobility was abolished in 1821; in Sweden it still survives. It is in Germany still important for many purposes to possess eight or sixteen quarterings—i. e. to be able to show purity of blood for four or five generations, the father and mother, the two grandparents, the four great-grandmothers, and also, in case of the sixteen quarterings, the eight great-great-grandmothers, having all been entitled to coat-armour. Among the higher grades of the peerage in England a considerable number may be pointed out who do not possess this complete nobility.

See the works of May, Hallam, Stubbs, and Herbert Spencer; Sir H. Nicolas's Historic Peerage (1829; new ed. by Courthope, 1856); Freeman's Comparative Polities (1873); also the Peerages of Dehraut (since 1802); Burke (since 1836), and J. Foster (since 1880).

**Noble**, a gold coin first minted by Edward III, and so called from its being of noble metal: on the one side was a ship, in allusion to Edward's victory at Sluys. The original value was half a mark, or 6s. 8d. A later issue (Edward IV.) bore a rose on the same side as the ship, and were called rose-nobles and roges Silver having depreciated, the value of the noble rose to 10s. (much greater purchasing value than now), and a new coin of the old value was issued, called the *Angel* (q.v.).

**Nocera**, an episcopal city of South Italy, 8 miles N.W. of Salerno. Pop. 12,322.

**Noctiluca** (lit., 'night-light'), a phosphorescent marine Infusorin, extremely abundant round British and other coasts, one of the chief causes of the 'phosphorescence' of the waves. It is a spherical animal—large for an Infusorin (2½ in. in diameter)—and moves by means of a long stout lash or flagellum, beside which there is a second, very much smaller, lying in the 'month' region. Its substance is remarkably spongy, and the phosphorescence is said by Allman to have its seat just underneath the rim. See *Infusoria*, Phosphorescence.

**Nocturne.** See *Breviary*.

**Nocturne** ('night-piece'), a dreamy musical piece, generally for the piano, especially associated with the times of Field (q.v.), its inventor, and Chopin. See *Music*, p. 338.

**Nodal Lines.** See *Harmonics*, Sound.

**Noddy** (*Anous*), a genus of birds of the family Laridae, differing from terns in having the bill slightly angular, thus exhibiting an approach to gulls, and the tail not forked, but somewhat wedge-shaped. Altogether seven species are enumerated, widely distributed throughout the tropics and in the temperate zones. One species (*A. stolidus*) has been recorded as found off Wexford and in Dublin Bay, but no specimens other than the two obtained being British have been found on the west coast or on the Continent. It is a familiar bird in the Atlantic and Pacific Oceans, not unfrequently alighting on vessels and suffering itself to be taken by the hand; and so at its breeding-places also, where, not accustomed to the visits of man, it becomes unshrinking in its approach, and the females disturbed on the nest. Hence it commonly shares with the booby the reputation of unusual stupidity. It is about 15 or 16 inches long, from the tip of the bill to the end of the tail, the general colour being a brownish black. The food consists chiefly of small fish and molluscs; but particular islands appear to seem to be specially selected as the breeding-places of noddies, among them being the Bahamas, many of the Keys of the West Indies, the Laccadives, St Helena, Ascension, and many islands of Polynesia and Australia. Their nests, which are built on shelves of rocks or patches of sand or on trees, are sometimes very closely placed together. Each nest generally contains only one egg, which is about two inches long and of a buff colour, sparingly speckled with reddish brown. The eggs are very slow to hatch, and in some cases the young remain for a large number of days. The other species of noddy are distinguished by their smaller size and slightly different colour.

**Nodes**, in Astronomy, are the two points in which the orbit of a planet intersects the plane of the ecliptic, the one through which the planet passes from the south to the north side of the ecliptic circle, called the *ascending node* (σ), and the other the *descending node* (ω). As all the bodies of the solar system, whether planets or comets, move in orbits variously inclined to the ecliptic, the orbit of each possesses two nodes, and a straight line drawn joining them is called the *line of nodes* of each body. It is scarcely necessary to add that as the earth moves in the plane of the ecliptic she has no nodes. The places of the nodes are not fixed points on the plane of the ecliptic, but are in a constant state of fluctuation, sometimes advancing (eastward), and at other times receding (moving westward). This motion is produced by the mutual attractions of the planets, which tend to draw each of them out of the plane of its orbit; and it depends upon the relative positions of the planets with respect to each other. We have no means of knowing whether that planet's nodes shall advance or recede. On the whole, however, the majority of possible 'relative positions,' or *configurations*, as they are called, is in favour of a retrograde motion; and we find by observation that in an average of many revolutions round the sun a constant retrogradation of the node takes place. The determination of this retrogradation in the case of the planets is a most complicated problem, as the separate action of each on the others has to be taken into account. The revolutions of the planetary nodes are accomplished very slowly, the time of completing one whole degree in a century. The nodes of the lunar orbit retrograde with much greater speed under the disturbing influence of the sun. It is owing to the fact that they complete a revolution in nearly eighteen Julian years and eleven days that series of eclipses recur at that period. See Eclipses, Orbit, Perturbations; and Herschel's Outlines of Astronomy.

**Nodes**, in Botany. See *Stem*.

**Nodler**, CHARLES, a considerable French writer, was born at Besançon, 29th April 1750 (Sainte-Beuve), in 1781 (Weiss), or even 1783 (Quérard), the son of a revolutionist lawyer. He lived a shifty life at Paris, Besançon, Dôle, Laibach, and last
again at Paris, where he was appointed in 1823 to the librarianship of the Bibliothèque de l’Arsenal. As a child an ardent Jacobin, he became a royalist at the Restoration, was elected to the Academy in 1833, and died 27th January 1844. He was a de- voted student of entomology, philology, and bibliog- raphy, but his importance in literature depends mainly upon the influence his personality exerted on a group of Romanticists of 1830. Most of his literary work is already forgotten, save his delightful- ly fresh and fantastic short stories, of which may here be named Smarra, Histoire du Roi de Bohême et de ses sept Châteaux, La Fée aux Miettes, Inés de las Sierras, La Legende de Sour Beatrix, Frederick the Great, and his volume of Fairy-tales. His Souvenirs de Jeunesse (1832) must not be taken too seriously. The Événements Complètes (12 vols., 1832-34) are far from complete. There are Lives by Wey (1844) and Mme. Ménestrier-Nodier (1867). See also Mérimee’s admirable Essay.

Noé. See CHAM.

Noctians. See PATRIPASSIONS.

Nogent-le-Rotrou, a town in the French department of Eure-loir, prettily situated on the Huilne, 93 miles by rail SW. of Paris. It is a long, well-built, place, with the ruined château of the dukes of Orléans, and a statue of General Saint-Pol, who fell before Sebapopol. The Germans here won two fights, on 21st November 1870 and 6th January 1871. Pop. 7346.

Nouvelle, a village of France, 5 miles E. of Metz, where, on 31st August—1st September 1870, Bazaine attacked the Prussian besiegers of Metz with 120,000 men and 600 guns. He had some success on the first day, against the 41,000 men and 138 guns commanded by Manteuffel; but on the second day gave up the attempt to break through the German line, which had been reinforced during the night by 30,000 men and 162 guns.

Nola, an episcopal city of Italy, 16 miles E.N.E. of Naples. It is built on the site of one of the oldest cities of Campania, founded by the Ausonians, and taken by the Romans in the Samnite war, 313 B.C. Augustus died here, 14 A.D. Pop. 7496.

Noli me tangere. See LUPUS, TUBERCLE.

Nollekens, Joseph, was born in London, 11th August 1737, the son of a painter from Antwerp. Being placed in the studio of Scheemakers the sculptor, he progressed so much that the Society of Arts repeatedly awarded him valuable prizes. In 1760 he settled in Rome. Garriek, whom he met there in the Vatican, immediately recognised his countryman as the young sculptor to whom the prizes had been awarded by the Society of Arts, sat to him for his bust, and paid him handsomely for it. He also executed in Rome a bust of Sterne in terra cotta, which added greatly to his reputa- tion. After residing ten years in Rome he returned to London, where he set up his studio; and the reputation he had acquired in Rome was such that he immediately had full employment, and within a year after (1771) was elected an Associate of the Academy, and a Royal Academician the following year. His forte was in model- ling busts; and through them he has handed down the likenesses of most of the important personages who figured in Great Britain in the end of the 18th and beginning of the 19th century—of Samuel Johnson, who was his friend and frequent visitor, of Fox, Pitt, and other political characters. George III. also sat to him. Besides busts, Nolle- kens executed numerous commissions for public monuments and statues. He also executed a number of classical and mythological statues and groups. He died in London, 23d April 1823, leav- ing no children to inherit a fortune of £200,000. See J. T. Smith’s Nollekens and his Times (1828).

Nolfe Prosequi, a term used in English law to denote that a solicitor of the bar cannot apply for ‘universals.’ It was contended by some that abstractions—as a circle in the abstract, beauty, right—had a real existence apart from round things, beautiful objects, rights actions. This was called Realism. Those who held the opposite view were called Nominalists, because they maintained that there was nothing general but names; the name ‘circle’ is applied to everything that is round, and is a general name; but no independent fact or property exists corresponding to the name. Specifi- cally the circle is a universal, an abstraction of ‘universals’ or of genera and species, and arose out of a passage in the Latin translation of Porphyry’s Isagoge. The watchwords of three schools were universalia ante res, ‘the universals before the concrete things,’ of Platonic Realism; universalia ex re, ‘the universals in the material things,’ of Aristotelian Realism; universalia post rem, ‘the universals after the thing,’ covering both Nomini- alism (that the universals were but Ratus vocis, sounds) and Conceptualism (that the universals had an existence in the mind of the thinker).

Scholastic Realism of which was regarded as the Aristotelian type prevailed until the 11th century, when Roscellin defended a distinctly Nominalistic doctrine. Unhappily he applied his philosophy to the doctrine of the Trinity, and arrived at a tri- theological heresy, which Nominalism with the Church was condemned by the church. Henceforward Nominalism carried with it, not unreasonably altogether, a savour of heresy and rationalism, and Realism was dominant, though the contro- versy raged throughout the 12th century. Abelard was a modern Scholastic; Albigensians, Aminus, and Dun Scotus were Realists of a kind, though in the 13th and 14th centuries the feud between Nominalists and Realists was no longer the central debate of scholasticism. Nominalism triumphed with William of Ockham (died 1347), with whom scholasticism may be held to have begun to dis- solve. See SCHOLASTICISM, and works quoted there; the articles on the chief medieval thinkers; the article PHILOSOPHY; and monographs by Exner (1841), Köhler (1853), and Löwe (1856).

Non-combatants. See COMBATANTS.

Non-commissioned Officers, in the British army (sous-officers in the French, and water-officers in the German army) is the most valuable and important class, intermediate between the commissioned officers and the men. It is essential that some persons in authority should live amongst the men, superintend their Mess (q.v.), teach them their drill and duties, take charge of small parties on duty and in the field, and, generally, overlook them in every way. None are so well fitted to do as those who are selected from amongst the men themselves, after several years’ service as private soldiers, for promotion to non-commissioned rank. They must be well qualified by good conduct, tact, temper, education, and knowledge of military
duties—in the two last mentioned they must pass examinations—and the efficiency of the corps will largely depend upon the way in which they do their duty. Besides extra pay, they enjoy special privileges, and many obtain commissions as officers. All corporals, all midshipmen, all officers of the Coast Brigade Royal Artillery and Coast Battalion Royal Engineers, and many combatant officers of cavalry and infantry are selected from amongst them. They can only be reduced to the ranks, or to a lower grade, by sentence of a court-martial and cannot be subjected to any inferior punishment except a reprimand. The following are included in the term ‘non-commissioned officer’; master-gunners, 3d class (who have charge of the armament and magazines in a fort), staff-clerks, all Sergeants (q.v.), Corporals (q.v.), and Bombardiers (q.v.). Sergeants have a separate Mess (q.v.), and in most barracks there is a corporals’ room. The proportion of non-commissioned officers to other soldiers in a battalion at war strength is 91 to 939; in a regiment of cavalry, 83 to 551; and in a battery of artillery, 21 to 55. To be promoted to the different class ranking above non-commissioned officers, from whom they are nearly all selected, but below officers: Bandmasters, schoolmasters of more than twelve years service, conductors of supplies or stores, master-gunners (1st and 2d class), superintendents clerks, class stars, sergeant-majors, and corporal-majors. For the Navy, see Petty Officers, Warrant Officers.

**Nonconformists**, a name sometimes given generally to all sectaries who, at any period in English history since the establishment of Protestantism, have refused to conform to the doctrine and practise of the Established Church. It is used in a restricted sense to denote the clergy who in 1662—two years after the Restoration—left the Church of England rather than submit to the conditions of the Act of Uniformity. In 1727 the Presbyterian, Independents, and Baptists received some special legal recognition, and came to be known as the Three Denominations. See England (Church of), Presbyterian, Independents, &c.

**Non-effective** (Fr. non-activité) is the term used to describe the status of officers of the British army or navy who are on retired or half-pay. Non-commissioned officers and men who are discharged, die, or desert are also said to become ‘non-effective.’

**None**, See Calendars.

**Nonius Marcellus**, a Latin grammarian, of whose life nothing is known. Little can be made of his surname Taburcicnus, but at least we may date him later than the middle of the 2d century, as he frequently copies A. Gallus, and earlier than the sixth, as he is frequently quoted by Priscian. His name is attached to a treatise in eighteen chapters, without arrangement or critical sagacity, but precious as preserving many words in forgotten senses, and passages from books of ancient Latin authors now lost. A good edition is that by Gerlich and Roth (1848); see also Professor Netleship’s *Essays in Latin Literature* (1885). A collation of the Harleian MS. of Nonius, by the late J. H. Onions (1852—59), was published in 1882 in the Clarendon Press *Anecdota*. The last seven years of this brilliant young scholar’s life were devoted to preparing a collation of the text of Nonius Marcellus for the Clarendon Press.

**Nonjurors**, the name given to that portion of the clergy in both England and Scotland who, having taken the oath of allegiance to James II., refused at the Revolution to take it to William and Mary. An act of parliament required them all to take this oath by 1st August 1689, six months’ grace being allowed before deprivation; but it was refused by Archbishop Sancroft of Canterbury, by Bishops Ken of Bath and Wells, Turner of Ely, Frampton of Gloucester, Lloyd of Norwich, White of Peterborough, Thomas of Worcester, Chesterton, and Cartwright of Chester (the three last died during the year), and by about 400 of the English clergy. In Scotland, where all the bishops refused the oath, Episcopacy was abolished in 1689, and more than 300 clergy were thrust out; and not till the death of Prince Charles Edward in 1788 did the Protestant bishops in Scotland, ‘upon mature deliberation with their clergy, unanimously agree to comply with and submit to the government of King George III.,’ nor until four years later did the bill for their relief receive the royal assent. South of the Tweed the schism was perpetuated by the consecration in 1694 of Hickey (q.v.) and Waggstaffe as suffragan bishops of Thetford and Ipswich, in 1713 of Jeremy Collier (q.v.) and two others, as also by the introduction in 1718 of the ‘usages’ (a new communion office, prayer for the dead, &c.), which were mixed bishops of differing class ranking above non-commissioned officers, from whom they are nearly all selected, but below officers: Bandmasters, schoolmasters of more than twelve years’ service, conductors of supplies or stores, master-gunners (1st and 2d class), superintendents clerks, class stars, sergeant-majors, and corporal-majors. For the Navy, see Petty Officers, Warrant Officers.

**Non Nobis Domine**, See Grace At Meals.

**Non Possumus** (Lat., ‘we cannot’), a papal formula taken from Acts, iv. 20 (Vulgate), and said to have been used by Pope Clement VII. in reply to Henry VIII.’s demand for the dissolution of his marriage with Catharine of Aragon; used in general expression for the refusal of the Roman curia to yield to the demands of the temporal power.

**Non-residence**. See Pluralism.

**Non-suit** is a legal term in England, which means that, where a plaintiff in a jury trial finds he will lose his case owing to some defect or accident, he is allowed to be non-suited, instead of allowing a verdict and judgment to go for the defendant. But there is now, in general, no difference between the effect of a non-suit and that of a verdict for the defendant.

**Non-user**. See Desuetude.

**Nootka Sound**, a harbour on the west coast of Vancouver Island, British Columbia, its entrance protected by an island of the same name.

**Norbertines**. See Premonstratensians.

**Nord**, the most northerly department in France (whence its name), corresponding with the former province of French Flanders, and bordering on Belgium and the Strait of Dover. Area, 2,198 sq. m.; pop. (1881) 1,063,520; (1891) 1,751,321. It is
NORFOLK

NORDAU

watered by the Sechelt and the Salishre, with their affluents, and has many canals. Next to that of the chief departments in France; Lille has 200,000 inhabitants, 
Ronbaix 115,000, and several towns have over 
30,000. In blood the people are Flemish and 
Wallon in about equal proportions; some 177,000
still speak Flemish. The soil is rich, the fisheries 
are abundant, the mineral wealth very great, 
especially in coal; and for manufactures Nord is 
one of the foremost of French departments. It 
possesses five first-class fortresses, and has been 
the scene of many great campaigns and battles.

Nordau, Max Simon, born of Jewish descent 
at Budapest, 1845, to the management, religious, and political 
principles were but Conventional Lies of Society 
(1883; 15th ed. 1890; Eng. trans. 1895); Paradizes 
(1886), and Degeneration (1893; Eng. trans. 1895), 
maintaining that most that is conspicuous in 
contemporary art, literature, and the sciences of 
the greater part is but the gross proof of 
physical and psychical degeneration. His novels (Gefiihls- 
kundige, &c.) have been more successful than his 
dramas and poems.

Nordenfelt. See Machine Gun.

Nordenskiold, Baron Nils Adolph Erik, 
Nordenskiöld, navigator, was born at Helsingfors in 
Finland, 7th February, 1832, son of the superintend 
ent of Finnish mines, and studied at home and 
in Berlin. In 1857 he naturalised himself in 
Sweden, and in the following year was appointed 
head of the mineralogical department of the Royal 
Museum at Stockholm. During the next twenty 
years he frequently visited Spitzbergen; in 1868 he 
completed the measurement of an arc of the meridian 
there, and mapped the south of the island. After 
two preliminary trips to the mouth of the Yenisei, 
by which he proved the navigability of the Kara 
Sea, he successfully accomplished June 7th and 
September 1879, in the celebrated Vega, the 
navigation of the North-east Passage, from the 
Atlantic to the Pacific along the north coast of 
Asia. On his return he was made a baron of 
Sweden (1880), and during the next five years 
published the journal of his voyage in the 
Vega round Asia and Europe (Eng. trans. 2 
vols. 1881), Scientific Results of the Vega Expedi 
tion (1883), and Studies and Investigations (1885). 
To Greenland, too, he has made two expeditions; 
members of his party on the second occasion (1889) 
reached a point 140 miles distant from the east 
coast, but without finding the ice-free interior 
Baron Nordenskiöld believed to exist. Three 
years later he published a book on the icy interior 
of Greenland. In 1891 he proposed to lead an 
expedition to the Antarctic islands. The expenses 
were borne in part by the Australian colonies. 
He died 12th August 1901. See A. Leslie's Arctic 
Voyages of A. E. Nordenskiöld, 1858-79 (1879).

Norderney, a small treeless island, lying 3 
and miles off the coast of the Prussian district of 
East Friesland, and forms one of a string of islands 
that lies 77,000 miles to the west of the Cape 
Verde. It enjoys a great reputation for sea-bathing, and 
in summer may have 13,000 or 14,000 visitors.

Nordhausen, a flourishing town of Prussian 
Saxony, pleasantly situated at the southern base 
of the Harz Mountains, and the west end of the 
ferile Goldau (or 'golden plain'), on the Zorge, 
48 miles by rail N.W. of Erfurt. St Blasius, one 
of its seven churches, contains two paintings by 
Cranach; and there are also a quaint town-hall, 
seventy extensive distilleries of corn-brandy or 
'Nordenhaisser schnaps' (11,000,000 gals. per annum), 
and manufactories of tobacco, sugar, leather, chemical, 
and dressing. From 874, and in 1253 created a 
free imperial city, Nordhausen embraced the 
Reformation in 1522, and in 1533 was joined to 
Lutheranism. Pop. (1875) 98,265; 1880, 174,743. See works by 
Fürstmann (1825-55), Lesser (1860), and Giesler 
(1889).

Nördlingen. a town in the west of Bavaria, 
is situated on the river Eger, 44 miles N.W. of 
Augsburg by rail. It has a Gothic church (re 
stored 1880), with a high tower and fine organ, 
and is built from 100 to 200 feet high. The name is 
commonly applied to the portion of the estuary in 
in the vicinity of the Nördle light and sand 
bank. It was here that the outbreak of the fleet, 
known as the 'mutiny at the Nördle,' broke out on 
20th May and lasted until 13th June 1797. The 
Englehard and the Comforter, in the name of the 
President of the 'Floating Republic,' was hanged on 
the 30th from the yardarm of his ship; and a 
few other men soon afterwards executed or flogged 
through the fleet. The King's Own, by Marryat, 
gives a sketch of the mutiny.

Norfolk, an important county on the east coast of 
England, is divided into shires only to 
Yorkshire, Lincolnshire, and Devonshire, is 
bounded N. and NE. by the North Sea, E. and 
S. by Suffolk, and W. by Cambridgeshire, Lincoln 
shire, and the Wash. With an extreme length 
and breadth of 66 miles by 42, it has an area of 
2119 sq. m. or 1,306,173 acres. Pop. (1851) 273,371; 
(1861) 390,000; (1881) 444,637; (1891) 454,516. 
Its coast-line, upwards of 90 miles in length, is for 
the most part flat, and skirted by low dunes, except 
near Cromer, and again at Hunstanton, where cliffs, 
from time to time undermined by the sea, are 
formed a height of 150 to 200 feet. Inland the surface 
is undulating, well timbered, and well watered, 
the principal rivers (by which, and by the Great 
Eastern and Eastern and Midlands Railways 
communication throughout the county is kept up) 
being the Ouse, which flows into the Wash, and the 
River, Yare, and Waveney, which fall into the sea near Yarmouth, and in 
their course link together the numerous Broads (q.v.) 
situate in the north-eastern district. The soil 
consists chiefly of light loams and sands—in places 
there are extensive rabbit-warrens, and with so 
much wood (51,258 acres in 1889) there is naturally 
an abundance of game. The climate, though in 
the spring-time cold owing to the prevalence of 
est winds, is on the whole dry and healthy. 
Apart from lime, chalk, and excellent brick-earth, 
no minerals of any importance are worked, but 
agriculture in all its different branches is here 
bring to the highest state of perfection; all the 
usual crops, especially turnips, swedes, and 
mangold, are extensively cultivated; upwards of 3400 
acres are occupied as market-gardens and orchards; 
whilst great attention is paid to the rearing of 
turkeys and geese for the London markets, and on 
the rich marsh-lands in the extreme west of the 
county, as well as on the pastures bordering the 
varying rivers, great quantities of cattle are grazed. 
The principal manufactures are noticed under 
NORWICH, and of other industries the most impor 
tant is the herring-fishery connected with
Yarmouth and other ports. Norfolk comprises 33
hundreds, the city of Norwich, the municipal
boroughs of King's Lynn, Great Yarmouth, and
Thetford, and the island of Orford (see latter
extending into Suffolk), and 736 civil parishes with
parts of 9
others, mostly in the diocese of Norwich. Its par-
liamentary divisions are six in number, each return-
ing one member, and the county council consists of
76 members. Towns other than the
parish church and cathedral are
Great Yarmouth, Diss, Dereham, Dickleburgh,
Dunwich, Southwold, and Wymondham. In the history
of the county the most notable incidents have been
the settlements within its borders of the Flemish
refugees and Walloons in the reigns of Henry 1st.
111, and Edward 1st, and then Elizabeth, and King
Edward 4th (1450). Many interesting traces of the
handiwork of its former occupants are still extant
in the ruins of priories at Castle Acre, Thetford,
and Walsingham, in the castles of Norwich, Castle
Rising (where Queen Isabella was confined a
prisoner), and Caister, in the church at Heckingham,
Caister, and Thetford, and in the old halls of Bick-
ling (the home of the Boleyns), Holkham, Hought-
on, Ovingham, and East Barsham. Among Norfolk
women's 'worthies' (omitting those noticed below
Norwich) are to be found the names of Gonville
(founded the University with his own name), Sir John Fastolf, the Earl of Surrey, Sir Thomas
Gresham, Skelton and Shadwell (poets-laureate),
Sir Edward Coke, his descendant the Earl of
Leicester, Spelman (the antiquary), Sir Roger
L'Estrange, Sir Claude Shovel, Sir Robert Wal-
pole, and also the oracles, Wheldrake (the topo-
ographer), Tom Paine, Windham (the statesman),
William Godwin, Lord Nelson, Professor Porson,
Manby (inventor of life-saving apparatus), Sir
Astley Cooper, Elizabeth Fry, Fellows Buxton,
Lord Cranworth, Captain Melville (the novelist and
painter), Borrow (the Romany
Rye), Bulwer Lytton, and Rioler Haggard.
For the Duches of Norfolk, see Howard.
See the county histories by Blomefield (11 vols.
1805-10), Chambers (2 vols. 1829), Lye (1888), and
White (new ed. 1891); also A. D. Bayne's Eastern
England (2 vols. 1873), G. C. Davies' Norfolk Broads
and Rivers (1884), and Jessopp's Arcady (1887).

Norfolk, a city and port of entry of Virginia,
on the right bank of the Elizabeth River, 5 miles
from Hampton Roads, and 38 miles from the ocean.
The city, which is largely built on low ground, and
contains a city hall, mechanics' and masonic halls,
custom-house, military academy, and Catholic
seminary, its large deep harbour is defended by
Fort Calhoun and Fortress Monroe. A govern-
ment navy yard, drydock, and hospital are at
Norfolk, a naval suburb of Portsmouth, on the
opposite bank of the river. Norfolk ships con-
siderable quantities of cotton, oysters, and early
fruits and vegetables; lines of steamers connect
it with New York and other cities, and three
trains enter here. The town was burned by the
British in 1776. The town's elevation between
the Merrimac and the Monitor (1862) was fought off
Norfolk. Pop. (1890) 34,871; (1900) 46,624.

Norfolk Island lies in the Western Pacific,
about half-way between New Zealand and New
Caledonia, 400 miles N.W., of the former. The
coastline is irregularly built on low ground, and
forms a narrow forest, with the exception of the
Governor's house and government, and the
surface generally uneven, rising in Mount
Pitt to 1050 feet. The island is 6 miles long, and
has an area of 134 sq. m. The soil is fertile and
well watered, and the climate healthy. The
Norfolk Island Pines grows to a height of 200 feet;
the Eucalyptus tree, or dwarf pine, is very
Norfolk Island was discovered by Cook in 1774.
Between 1788 and 1805, and again between 1826
and 1855, it was a penal settlement for convicts
sent from New South Wales. In 1856 many of the
inhabitants of Pitcairn Island (q.v.) were transferred
bitterly by the British government to the pop.
741. This included about 150 Melan-
esean boys and girls being educated at Bishop
Patteson's mission-station of St Barnabas. Norfolk
Island being the headquarters of the diocese of
Melanesia, which was founded in 1801. The
people govern themselves, meeting the superin-
tendents of the missionary station of New South
Wales; they fish, farm, and supply provisions to
passing vessels.

Norham Castle, the Border fortress of the
Bishops of Durham, on the right bank of the
 Tweed, 8 miles SW. of Berwick. Founded in
1121, and deemed impregnable in 1229, it has
memories of Kings John, Edward 1, and James
IV., but is known best through Marmion. The
picturesque ruins comprise a great square keep,
70 feet high. See Hubert Jenkins' Norham
Castle (1883).

Noricum, a Roman province, situated between
Rhaetia on the west and Pannonia on the east,
and corresponding to the area between the Danube,
Styria, Carnithia, and part of Salzburg. The Roman
emperor Trajan subdued the native Celtic Norici or Taurisci in
15 B.C. The name survives in the Noric Alps;
see Alps.

Normal Schools or Training-Colleges,
institutions which teach or instruct in the
principles of their profession and trained in the
practice of it. See Education, Vol. IV, pp. 211,
217.

Norman Architecture, a style originated
and chiefly used by the Normans. Soon after their
conquest of the north of France they began to erect
churches and castles on an extensive scale.

...
that found in the country. The chapel of St John, on the second floor of the White Tower of London, is the earliest example of pure Norman work in England, that ancient keep having been built by William the Conqueror in 1078. There are, however, many buildings, both in England and Scotland, which date from before the end of the 12th century, when the pointed style began to be used:

Durham, Lindisfarne, Canterbury, Dunfermline are partially Norman, besides many other churches and castles. The Anglo-Norman is heavier than the French-Norman, the cylindrical nave piers of the English buildings being much more massive than those of French works. To relieve this heaviness the chevron, spiral, and other groovings were cut in the pier. The mouldings and forms of doors and windows are the same as those of Normandy. There is one remarkable difference in the plans of the Early Norman churches in the two countries: in France the apse at the east end is always semi-circular, but in England this form was gradually given up, and towards the end of the style the square east end was generally adopted.

Normandy, a town in the North Riding of Yorkshire, 3½ miles SE., and mainly within the parliamentary boundary, of Middlesbrough. Pop. 9114. It has given the title of marquis to 1694 to John Sheffield (q.v.), Earl of Mulgrave and afterwards Duke of Buckinghamshire, as also in 1888 to Constantine Henry Phipps (1797–1863), previously Earl of Mulgrave, and a distinguished statesman.

Normandy, formerly a province of France, lying along the seaboard of the English Channel, between Brittany and Flanders, its eastern boundaries being marked by the little rivers Epte and Cotentin, and its western by the Coniendam. In area it corresponded approximately to the modern departments of Seine-Inferieure, Eure, Orne, Calvados, and Manche, its capital being Rouen. It is on the whole a fertile region, with well-cultivated fields and many smiling orchards, filled with apple trees, from the fruit of which cider is made. The people are intelligent and industrious, and rank amongst the best and most energetic of French provincials. When the Romans were masters of Gaul this portion of the country formed part of Gallia Lugdunensis Secunda; after the Franks' invasion it made a constituent part of the kingdom of Neustria, and was given by Charles the Bald to the Duke of Paris. From the middle of the 9th century its coasts were harried by the vikings or sea-rovers of the north (see Normans); shortly after the 10th century began they established themselves in such force along the Seine that Charles, king of the Western Kingdom, was glad to make a definite agreement with their leader Rolf (Rollo, Roll) and Chaillot Espe in 912. Rolf, Duke of the Northmen, became the vassal of the king, but wrested his lands from the Duke of Paris, and consequently had him for an enemy all his life. Rolf at the same time became nominally a Christian, taking at his baptism the name of Robert. His successor was his son William Longsword, who declared himself King Charles's vassal in 927. His father had conquered lands to the west of those originally granted to him; William added the Cotentin, or peninsula of Manche, and thus extended the duchy westwards to Brittan and the sea. This seems to have done partly with the help of Normans from the north, who settled there. Thus there were striking differences between eastern and western Normandy; the former rapidly adopted Christianity, the French language (tongue d'or), and the manners and customs of the French, whilst the newer districts stuck stubbornly to their heathen faith and customs and their native Norse tongue. Open war was waged between the rival parties not only during the lifetime of William, but of his son and his successor, Richard the Fearless (943–996), who overcame the heathen and Scandinavians, the help of King Louis and the Duke of Paris. Louis then attempted to make himself master of Normandy—Richard being a youth—but was frustrated by Hugh of Paris, who now sided with the Normans. In 987 Hugh became king of the Western Kingdom of France; and the good understanding established between Normandy and France lasted from that time down to the accession of William, the Conqueror of England, his fourth cousin. Richard the Fearless, to rule in 996, and, dying in 1026, left his son Richard as his successor. It was during his reign that Normandia began to be substituted for Land of the Normen; hence Normandy and Normans. The second Richard married, first Etheldred of England, and second Canute (Knut) of Denmark and England; this knit the first close ties between the ruling families of England and Normandy. The third Richard was succeeded after a reign of two years by his brother Robert, who died on his way back from a pilgrimage to Jerusalem in 1035, leaving as heir to the duchy his natural son William, at that time a boy. During William's minority the duchy was the scene of anarchy and confusion. The western portion made an attempt to assert its independence, an attempt which was crushed by Hugh, who received the help of the king of France at Val-d'Es-Dunes (1047). The next twenty years are written glorious in the annals of Normandy. William ruled with vigour andprudence; he fostered the noble houses, but kept a firm hand on the nobles who encouraged the churches, yet preserved the control of church matters himself; thoroughly established the feudal system; gave countenance and support to learning (Lunfranc, Anselm); and favoured the building of magnificent abbeys. He also waged war with the Count of Anjou, his southern neighbour, for the county of Maine, and conquered it in 1063; and even fought against the king of France, who
Normanton, a town in the West Riding of Yorkshire, by rail 3 miles NE. of Wakefield and 10 SE. of Leeds, an important railway junction, and seat of coal-mining and iron-working. Pop. 10,274.

Norse. See Iceland, Saga, Scandinavia, Northmen.

North, a family famous in the history of England, the most illustrious members of which were three of the sons of Dudley, fourth Baron North of Kirtling in Cambridgeshire, all of whose lives fortunately were written by their youngest brother Roger, who has also bequeathed to posterity an interesting and characteristic, but unfinished, autobiography. The life of the first, Sir Edward North (1496-1564) was famous as a lawyer, and was created Baron North of Kirtling in Cambridgeshire in 1554. His second son was Sir Thomas North, of whose life we know but little save that he was still living in 1583 when Harriot's North (1579-1584), whose son, William-Henry John, succeeded as

Norristown, capital of Montgomery county, Pennsylvania, on the left bank of the river Schuylkill (crossed by three bridges to Bridgeport), 17 miles by rail NW. of Philadelphia. It contains a fine marble court-house, a state asylum for the insane, a number of cotton-mills and woollen-factories, rolling mills and foundries, flour-mills, and manufactories of glass, tacks, &c. Pop. (1880) 13,043; (1900) 22,265.

Norrköping, the first manufacturing town of Sweden after Stockholm, stands at the head of the Bråviken, 113 miles by rail SW. of Stockholm, and is a well-built modern town. First founded in 1264, it has had various times destroyed and burnt. The rapid river Motala, which connects Lake Vetter with the Bråviken, and which is spanned by several substantial bridges, affords considerable water-power, by which the numerous manufactories are worked. Here are cloth-mills, cotton spinning and weaving, manufactories of sugar, paper, calicoes, &c., and shipbuilding (gunboats, &c.). Here Charles IX. (1604) and Gustavus IV. (1809) were crowned. Pop. (1893) 34,325.

Normanton, a town in the West Riding of Yorkshire, by rail 3 miles NE. of Wakefield and 10 SE. of Leeds, an important railway junction, and seat of coal-mining and iron-working. Pop. 10,234.

Norwich, the Parce of Scandinavian mythology, were three maidens, by name Urd, Verdandi, and Skuld—i.e. Past, Present, and Future. They sit by the well of Urd, under the world-tree Yggdrasil in Midgard, and there dominate both of gods and men. Besides these three there are many inferior norns, both good and bad, answering to the genii of classical mythology; to such are attributable the unequal destinies of men in the world. Women who possessed the power of prediction were also born those of the race.

Nornhka, Fernando, a group of small islands belonging to Brazil, in the South Atlantic, about 200 miles ENE. of Cape San Roque. The group, which comprises a main island, 61 miles long and about 2 broad, and several smaller islets, is of volcanic character, phonolite and other rocks of late formation resting on a foundation of basalt. A curious calcarious sandstone is also common, consisting of sand and fragments of shells, rendered firm by the action of water. The climate is healthy, and the trade-winds keep the temperature moderate. The islands are fertile, and maize, sugar, sweet potatoes, cassavas, melons, and bananas are raised. The low hills and valleys of the main island are richly covered with plantations, which, however, are not many, and the lantana (q.v.), drops aerial roots from its branches. The group was visited in 1775 by Captain Cook, and in 1832 by Darwin, who investigated its geology. The Challenger Expedition explored the smaller islands. The main island has been named by the Portuguese Fernando; about 1500 convicts are kept, guarded by 200 soldiers.

Norrington, Robert, of Normandy, whose son Robert rebelled against him in Normandy, and a war broke out with France, in which William (q.v.) lost his life. The incapable Duke Robert mortgaged his dukedom to his brother, Bishop Stephen of Bayeux, and joined his forces to the East. After his return he was defeated and imprisoned by his brother Henry I., who ruled Normandy till his death (1135), notwithstanding the efforts of Robert's son William to dispossess him. After the accession of Stephen as English Matthew his husband, Geoffrey of Anjou gradually made himself master of Normandy (1139-45), but after reigning five years he resigned it to his son, afterwards Henry II. of England. Richard I. and John were the next dukes, but the duchy was taken away from John by the king of France (1203-4), on the plea that as the mather of his nephew Arthur he (John) had forfeited his French fees. The claim to the title was, however, only formally renounced by Henry III. in 1239. Twice subsequently Normandy was in English hands: Edward HI., conquered the Normans and Hopen (1317-18); in 1346, the English were finally driven out in 1420. The Channel Islands (q.v.) are a remnant of the Norm land possessions still belonging to the descendants of the Norman kings of England. For map, see France in provinces; for the Norman-French and Anglo-Norman, see English Literature, Vol. IV. p. 366; France, Vol. IV. p. 785; and Romance Languages.

Customary Law of Normandy.—The duchy was governed by customary law, which grew up principally out of local usages; at first it was the same as the customary law of England. Even down to the present day the law administered in the royal courts of the Channel Islands is virtually the old customary law of Normandy. One feature survives in the Cry of Haro (q.v.). This ancient customary law of Normandy seems to have been collected in writing on three separate occasions. The earliest collection was apparently written down by private persons in 1200 and about 1220, and had no official character; the third collection (1385) is a revised edition of the second, the Grand Conditit (a compendium or history of the 14th century). See Sir Travers Twining, in Academy, 24th June 1862.

See Freeman, Norman Conquest (5 vols. 1877); Palgrave, History of Normandy (4 vols. 1878); Planché, The Conqueror and his Companions (1874); Spence, Dreamland in History (1890); and topographical works by Blackburn (1809) and K. Macquoid (1874).
eleventh Baron North in 1834. The other honours of the third earl devolved upon his brother, Francis, fourth earl; and next on another brother, Frederick, fifth earl; on whose death in 1827, the earldom reverted to his cousin, Francis, sixth earl; who was succeeded by his grandson, Dudley-Finch, and lived there by his son, Frederick-George, eighth Earl of Guilford.—FRANCIS NORTH, second son of Dudley, fourth Baron North, was born 22d October 1937. He had his education at Bury and St John's College, Cambridge, studied law at the Middle Temple, entered the House of Commons in 1753, and died 5th September 1793. We know of his love for music, his kindness to his brothers and sisters, his dislike of witchcraft trials, and his distrust of all the many plots of the time. After the king's death he was much vexed by the insinuations that his brother, Jeffrey Finch, had of his uncle Finches, and in 1785, but soon after died, 5th September 1785.—SIR DUDLEY NORTH, the third son, was born 16th May 1741, and, like his brothers, educated at Bury. Even at school he was a trader, and at an early age he was bound to a turkey merchant in London. Ever the industrious apprentice, he soon setled himself with cock-fighting and swimming. He made a voyage to Archangel, next to Smirna, where he settled for some years in trade. Afterwards he settled in Constantinople, returning to England some years after with a considerable fortune, which he continued to increase by keeping an interest in the Levant trade. He became one of the sheriffs of London, and was pliant enough in the interest of the crown. He was knighted, married the widow Lady Gunning, and was appointed a Commissioner of the Customs and then of the Customs again. Under James II. he sat in parliament for Hanbury, and after the Revolution made but a sorry defence of his actions as sheriff. He was a keen-eyed observer of men and manners, had great mechanical genius, a passion for art and literature, and was rather the keeper, soon rose to a lucrative practice at the bar. At the Revolution his hopes of advancement were closed, and he cast in his lot with the non-juring party, and retired to his estate of Rougham in Norfolk, where he indulged the family passion for building, and acted as trustee for his great, brother's estate at Wroxton. In 1796 he married, and lived henceforth the life of a country gentleman and virtuoso, his only unusual taste being a passion for acquiring books, and for planting trees. He died 1st March 1794. His three hyper-erulogistic biographies, his autobiography, with all its naïveté of detail and its amusing prejudices, and his Examen (1740) of Dr WhiteKennet's History of England give him a place in English literature which he outlived with his own merits.—FREDERICK NORTH, eighth Lord North and second Earl of Guilford, a famous English minister, was born April 13, 1732, and educated at Eton and Trinity College, Oxford. When only twenty-two he entered the House of Commons in 1754, and in 1759, having inherited the Tory politics of his ancestors. On the death of Charles Townshend in 1767 he was made Chancellor of the Exchequer and leader of the House of Commons, a post for which he was well qualified by his eloquence, good humour, wit, and readiness of resource, even against such antagonists as Fox and Burke. In 1770 he succeeded the Duke of Grafton as prime-minister. North was largely responsible for the measures that brought about the loss of America; as a minister of the first order he rendered his country a judgment to that of the narrow-minded and obstinate king. Indeed, North was called by Horace Walpole the ostensible minister; the real minister was George III. In 1778 he renounced the right of taxing the colonies, already in the hands of the British Crown, but not annexed to the British Constitution, in order to keep America from being a country of union with the other colonies. Owing to the terms of peace with America led him to enter into a coalition with North, whom he had for so many years inveighed against as a minister without foresight, treacherous, vascalating, and incapable. North and Fox took office under the Duke of Portland in 1783, but the coalition destroyed Fox's popularity, and the Portland administration only lasted a few months. North was afflicted by blindness during the last five years of his life. He succeeded to the earldom of Guilford in 1790, on the death of his cousin, and died 28th August 1792.—BROWNLOW NORTH, evangelist, was grandson of that Brownlow North (1741-1820), Bishop of Lichfield, Worcester, and Winchester, whose son succeeded in 1827 as sixth Earl of Guilford. Born at Chelsea, January 6, 1810, he spent six years at Eton, travelled abroad, gambled, and lived much in the north of Scotland, but underwent conversion in 1834, and thereafter devoted himself entirely to evangelical labours under the Free Church of Scotland, as well as in Ireland and England. He died at Pullichewan in Dumfrieston, November 9, 1875. See his Life by K. Moody-Stuart (1879).
Peterborough the county is flat, and forms part of the Bedford Level (q.v.), but elsewhere the surface is undulating, the highest ground—about 390 feet above the sea-level—being found in the neighbourhood of Daventry. It is traversed by the London and North-Western, Midland, and Great Northern railways, and communication by water is maintained by canals and the Thames. As for the chief rivers, as also by the Grand Junction, Union, and Oxford canals. The soil, a black, peaty mould in the north-east, and a brown loam on the uplands, is on the whole very productive. Corn and green crops are largely grown; but, as compared with the predominating crops of other counties, the area devoted to these crops in 1899 showed a decrease of 960 acres. On the broad pastures many cattle are grazed, and dairy-farming is carried on, but, although Northants is a great hunting county, the breeding of horses is not much encouraged. The principal minerals are limestone, which is quarried in the north-east, and ironstone of excellent quality, which is found near Kettering and Wellingborough; in 1889 the amount of ore produced was 1,237,080 tons, whilst 230,820 tons of pig-iron were made. The manufactures are comparatively few. The return for 1871 apart from those noticed under Northampton. The county comprises twenty-two hundred, the municipal boroughs of Brackley, Daventry, Higham Ferrers, Northampton, Peterborough, and Stamford (the last two extending into Huntingdonshire and Lincolnshire), and has in all 344 civil parishes, with parts of fifteen others, almost entirely in the diocese of Peterborough. The parliamentary divisions are four, each returning one member, whilst the county council (exclusive of that for the Soke of Peterborough, which has forty members) numbers sixty-eight. In history the principal incidents connected with this county are the sieges in 1264 and 1265, and the executions of those noticed under Northampton (its capital), have been the battles of Edgecote (1469) and Naseby (1645), the beheading of Mary Queen of Scots at Fotheringhay Castle (1587), and the imprisonment of Charles I. at Holmby House (1647). Of its natives, besides Richard III. (and perhaps Catherine Parr, the best known are Archbishop Chichele (the founder of All-Souls' College at Oxford), Sir Christopher Hatton (the courtier), Catesby (of Gunpowder Plot renown), Thomas Fuller, James Harrington, Bishop Cumberland, Dryden, Charles Montague, Earl of Halifax, William Law, Gill and Carey (the eminent Baptists), Dodridge (the Nonconformist), James Hervey, Cartwright ('the father of Reform'), Dr. Paley, William Lisle Bowles, Clare (the peasant poet), the Earl of Carlisle (leader of the Baldechino charge), and Dean Mansel. See the county histories by Bridges (2 vols. 1791), Baker (2 vols. 1822-41), and Willan (2 ed. 1874).—Hampshire (q.v.) is the county of Southampton.

North Berwick, a fashionable watering-place of Haddingtonshire, at the entrance to the Firth of Forth, 23 miles by a branch-line (1848) E.N.E. of Edinburgh and 10 by water SSE. of Elie in Fife. The town stands on an elevated Conical Hill (219 feet); and westward stretch splendid golf-links with an 18-hole course. Tantallon Castle, 3 miles E., fronting the Bass Rock (q.v.), is a magnificent ruin, finely described in Scott's Marmion. A stronghold of the Douglasses, it resisted James V. in 1528, but in 1630 was 'slain down' by the Covenanters. Robert III. made North Berwick a royal burgh, and till 1835 it returned, with Haddington, &c., one member to parliament. Pop. 2376. See Ferrier's North Berwick (11th ed. 1860).

Northbrook. See BARGY.

North Cape, the northermost point in Europe, in 71° 10' N. Lat. It is not however on the continent, but on the island of Magde. The northermost point on the continent is Cape
North Carolina, one of the thirteen original states of the American Union, is situated on the Atlantic ind, between Virginia and Georgia, in 33° 50'–36° 35' N. lat., and 73°–74° W. long. Its extreme length is about 500, its breadth 186 miles. Area, 52,250 square miles, or larger than that of England. The eastern part of the state is low, and in some places enjoys the shelter of the western mountains; but everywhere, except in limited areas in the eastern section, the soil is remarkably fertile and the climate salubrious. The highest mountains in the United States east of the Mississippi are in North Carolina, at least twelve peaks being higher than Mount Washington, in the White Mountains, and more than fifty exceeding 6000 feet in altitude—Mitchell's Peak (6707 feet) the highest. Most of these are clothed to their tops with thick forests, but some have prairie-like summits covered with deep turf. All this picturesque region, known as 'the Land of the Sky,' is a favorite resort in summer for southerners and in winter for northerners.

North Carolina is rich in mineral products. The value of its gold and silver deposited for coinage and currency is estimated at £1,800,000. A branch U.S. mint was established at Charlotte in 1838, and has since 1873 been continued as an assay office. Silver occurs associated with lead in Clay and Davidson counties, and zinc in the Iatter county. Iron is widely disseminated in the form of specular hematite and magnetic iron; copper and plumbago also are found in the mountain counties. Bituminous coal of excellent quality is mined, 19,000 tons being raised in 1897. There are valuable deposits of coal, and extensive beds of mica in the west, quarries of brownstone and granite, and mines of tale, all of which are worked in the eastern section are valuable phosphate beds; and more than 150 species of gems, &c., including the rich 'hideenite' or leith-a-meral, which is not known to occur elsewhere, are found in the state.

Maize has hitherto been the principal agricultural product, but has recently been rivaled by cotton in the annual value of its crop. Wheat, oats, hay, tobacco, and sweet potatoes are the next most valuable products of the soil. One of the most important products of eastern North Carolina has been the production of tar, resin, and spirits of turpentine from the forests of long-leaved pine (Pinus palustris) and allied species. The manufacturing industries until 1880 were limited, but since that date the spinners and looms for the manufacture of cotton and woolen fabrics have been largely increased, tobacco-factories have been established and enlarged, and in 1888 the first silk-factory in the southern states was established. Fisheries constitute a profitable industry along the coast, and employ from 6000 to 7000 men.

North Carolina contains 97 counties, and returns ten members to congress. It has about 3700 miles of railway. The largest city is Wilmington, the capital Raleigh. In 1890 there were 7250 public schools (4675 for whites and 2374 for coloured), with an enrollment of 348,616 pupils. Besides several denominational colleges, there are a state university (1795) at Chapel Hill, and a state agricultural college established at Raleigh in 1889. There are asylums for the insane at Goldsboro, Raleigh, and Morganton—the first for negroes only; and provision is also made by the state for the blind and deaf-mutes, both white and black. The penitentiary has about 1300 convicts, but most of them are hired out by contract.

History.—In 1584 Raleigh's first expedition landed on Roanoke Island, and was kindly received. In 1585, 1586, and 1587 Raleigh planted colonies on the island, but the first returned with Drake in 1586, and the others were destroyed. In 1620 Charles I., claiming under Queen Elizabeth, granted to Sir Robert Heath the territory, also claimed by Spain and called Florida, from lat. 30° to 36° as Carolina Florida. By the English it was called both Carolina and Carolina. In 1636 the colony was settled on the banks of the Roanoke and Chowan rivers; this was the first permanent settlement in North Carolina. In 1663 Charles II. granted the region across the continent between lat. 31° and 36° to eight of his favourites, under the name of Carolina. In June 1665 the king extended the limits of Carolina to 29° on the S. and to 36° 30' N. The proprietors, 'to avoid erecting a numerous democracy' in Carolina, adopted a utopian form of 'fundamental constitutions,' prepared by John Locke and Shattesbury, which recognised a nobility of landgraves and casquins. The eldest proprietor was palatine, and the other seven had high-sounding titles. The proprietary rule ceased in 1729, when the king bought out the claims of the proprietors for £2500 each, and North Carolina became a royal province. Under the administration of the second royal governor, Governor Moore (1734–38), the colony increased in population from 14,000 to 45,000, and became very prosperous. The arbitrary rule of Governor Dobbs (1734–36) and Governor Tryon (1766–73) served to intensify the dislike of the people to the taxation policy of parliament; and when the colonial assembly at Wilmington protested against taxation without representation it was dissolved by Governor Tryon. The Mecklenburg Convention met at Charlotte and adopted a declaration of independence on May 20, 1775. The early years of the war (1775–83) were marked by bitter local and partisan conflicts between Whigs and Tories. In the years 1779–81 North Carolina furnished about one-tenth of the American army; still, it was the last state but one to ratify the federal constitution, November 21, 1790. It was the last, too, of the seven Confederate States to pass in convention an ordinance of secession, on May 21, 1861, which was not submitted to the people. The capture of Fort Fisher in January 1865 led to the federal occupation of Wilmington, the advance of the union forces on Raleigh, and the surrender of General Johnston, which marked the end of the war of secession. Pop. (1800) 487,103; (1840) 753,419; (1890) 1,617,947; (1900) 1,892,810—making North Carolina the fifteenth state in order of population. Presidents Jackson, Polk, and Johnson were natives; and Floria Mcdonald (q.v.) for a time resided here.

Northcote, Sir Stafford. See Iddesliegh.

North Dakota, one of the two states constructed in 1889 out of the former territory of Dakota (q.v.). Area, 70,795 square miles. Pop. (1900) 319,146.

North German Confederation. See Germany, Vol. V. p. 184.

Nor’men, or Norsemen, the name given in the middle ages by the coast-dwellers of Germany, Denmark, and Sweden, to the Scandinavians who came from the north—Denmark, Norway, Sweden. In a narrower sense the word sometimes means the inhabitants of Norway only. The most prominent characteristics of these North Teutonic tribes were their love for the sea and for war. Bolder navigators than the British Pluenevels they were, and were more east, west, south, and even north into the Arctic Ocean, to indulge their passion for fighting, to win fame, to gain wealth, to plunder, and to slay. We
nowadays should call them pirates; they called themselves sea-kings, vikings, and were, in fact, the first sea-rovers, who are often credited as the earliest navigators and most honorable work they could put their hands to. They believed too that the best title, in the legal sense, to land and other (movable) property was given by winning it with the sword: this gained them the highest respect and influence, and was the easiest guarantee of political power. There were likewise powerful economic and political causes co-operating with these to seal forth, from the middle of the 8th century to the 13th, and even later, these thronging swarms of Northmen. The natural resources of the lands they invaded in very land very inadequate to the support of the relatively large populations. The system of land tenure, based on the indivisibility and absolute ownership of the family estate, whilst fortifying the sense of family attachment and fostering family pride, frequently imposed galling restraints upon the younger sons, especially the more restless and high-spirited among them. Hence they spent the summer in quest of fame and booty in distant lands; but generally came home again in the autumn, to pass the winter in the enjoyment of the good things they had earned. Still stronger incentives were given to these expeditions when the more powerful chiefs (kings) at home began to subdue their weaker contemporaries and rivals, and the separate kingdoms (Norway, Denmark, Sweden) began to take definite shape, under such strong rulers as Harold Fairhair (Haarfager) and Canute. More powerful and purposeful ships would be needed to submit to the feudal vassals of the conquerors, preferred to abandon their homes, and go and conquer new lands for themselves elsewhere. These strong rulers moreover sternly put down the intestine feuds by which the Northmen delighted; consequently to get their fill of fighting they were obliged to go abroad.

A favourite plan of the weaker viking chiefs was to lie in wait up some small creek or river-mouth, or behind the shelter of some island, and thence suddenly dart out upon a passing vessel. The larger fleets boldly invaded a district, plundered the inhabitants, slew them if they offered resistance, or carried them off as slaves if they did not, harried the open country, rifled the churches and monasteries—which always yielded the greatest store of gold and silver—and not infrequently burned them to the ground, as they did the strong cities they took and sacked. Being heathens, worshippers of Thor and Odin, they had no qualms of conscience as to sacrilege, and stood in no awe of the threatenings of the church. One viking fleet would even challenge another to fight it for fighting's sake only. The vessels they sailed in were comparatively small and light of draught, so that they were able to penetrate a long way up the rivers, sometimes into the heart of a country; and as the Northmen were restless in arms and unremitting in their wrath, their mere appearance was often sufficient to paralyse an entire district with panic terror. In many churches a special petition, 'From the fury of the Northmen, O Lord, deliver us,' was recited in the litany. But these sea-rovers were also keen traders: on many occasions they first requested permission to land and trade peacefully with the inhabitants, and only when their trading was done did they begin to plunder. There were several recognised trading-places along the shores of the Baltic, and some on the North Sea, which were visited not only by legitimate merchants from England, France, or Flanders, but also by vikings who had slaves, and gold and silver, and other less valuable booty to dispose of.

The viking age is divisible into two periods: during the first adventure and plunder were the chief incitements—this lasted until the middle of the 9th century; the second was the period of permanent conquest in Ireland, France, England, and South Italy. The sea-rovers made their first recorded attack upon England, upon Wessex, in 787, and first began to raid along the shores of Frisia, Flanders, and France towards the end of the century. These bands came from Denmark, but may nevertheless have been, at least for a short time, recruited from Norsemen. During the first half of the next century the depredations of the Northmen were more terrible than ever, especially in Frisia and Flanders, during the periods 834-37 and 845-850. They had also gone farther south: in 829 a band reached Aquitaine; fifteen years later, bands from the land of Neirmontier; in 843-844 a fleet sailed up the Loire and Gironde, visited Galicia (Spain), and steered up the Guadalquivir and fought the Moors. From about the middle of the century bodies of Northmen established themselves in permanent camps at the mouths of the French rivers, and repeatedly ascended them on their errands of plunder and slaughter. Three times in quick succession they took Paris and stripped it of its wealth (845, 857, 861); but the most famous siege took place in 859 when their exceptionally adventurous fleet entered the Mediterranean, ravaged the coasts of Spain and Mauretania, and Majorca, spent the winter at the mouth of the Rhone, and in the following summer laid their ruthless hand on the coast towns of Italy, especially on Amalfi (near Carrara), thinking it Rome. Yet Flanders and the north of France suffered most during the thirty-six years from 870 to 912. During all this period a large army, or even armies, dominated the coast districts from the Rhine to Brittany, quartering themselves in the large towns, extorting tribute, and not only routing the fleets, but also actually invading and ravaging the country. The first armies of the weak kings of Austrasia and Neustria, and their still weaker vassals, but even making disastrous raids far into the interior—to Coblenz, Soissons, Sens—and exorting from kings, dukes, counts, and towns large sums of money and silver, and afterwards taking a share of the spoils of these incursions, were repeated until the 9th century.

The chief of these formidable bands were Bjorn Ironside, Hasting, Siegfried, Golfred, and Rollo or Rolf. Detachments of the main body crossed over more than once to England, where, however, Alfred was a match for them. Rollo (Ron) is probably the same as Rolfr the Gangar; if so, he was the son of a chief of the west coast of Norway, and was outlawed by Harold Fairhair shortly after 872. In 912 Charles the Simple of France, seeing that it was hopeless for him to drive away his dangerous and pertinacious foe, thought it best to disarm them against himself, and at the same time arm them against new-comers, by allowing them to settle in his kingdom, a plan adopted by other rulers before. Accordingly at Clair-sur-Epte he agreed to receive the district bounded by the Channel, the Seine, and the Loire to the south, and to let the Northmen become his men or vassal, and be baptised a Christian. Rollo accepted the terms, and thus acquired the nucleus of the duchy of Normandy (q.v.). There the name Northmen was softened into Normans, a name celebrated in history only in virtue of the conquest of England by Duke William, but also because of their exploits in Italy and Sicily, and the East, described under Guiscard and Sicily.

The earliest serious attacks upon England were made in 793 and 794, when Lindisfarne and Jarrow monastery was sacked. In 866 the Northumberland ravaged. It was about the same time that the sea-kings of Norway began to cross the 'Western Seas,' and sail as far as the Ryderlor or South Islands—i.e. the Hebrides, the Western Isles of Scotland, and Man (q.v.)—and to Ireland, prob-
ably utilizing the Faroe (q.v.) and Shetland (q.v.) islands as resting-stations. They sacked Iona (Hyn.) in 802 and again in 806, slaying most of the monks. Their visits to Ireland were particularly numerous after 807, and brought great woes upon the unhappy island. A chief named Torgil, a Norseman, conquered most of north Ireland shortly after 840. In the west of England a firth of Essex was disputed fiercely with the Norsemen, or, as the Irish called them, the Eastmen; but in the year quoted Olaf the White of Norway founded the Scandinavian (chiefly Danish) kingdom of Dublin, which lasted three centuries or more, beyond two of his successors. His successors, Waterford and Limerick (see IRELAND, Vol. VI. p. 203). The Faroe, Orkney, and Shetland Islands seem to have been frequently visited by Norsemen after 825, and were permanently colonised during the next quarter of a century. Iceland (q.v.) was discovered and colonised by the same people between the middle and end of the century; and from Iceland they ventured still farther west, and made settlements in Greenland (q.v.), and even visited Vinland (q.v.) in North America. The Vikings also raised many small trading- and fishing-vessels. They were incessant after 833, but were checked for a time by the great slaughter inflicted on them by Ethelwulf at Ockley (Surrey) in 851. Fifteen years later they began again, and this time assumed the character of a serious invasion, the invaders being almost exclusively Danes. The Vikings were absolute masters of the northern, and more especially the eastern, portions of the island, notwithstanding the heroic efforts of Alfred and his son Edward. The struggle is sketched under England (q.v.).

By the middle of the 8th century the Norwegians had discovered the sea-route to the White Sea by rounding the North Cape. On several occasions down to 1222 they sailed up the Northern Dvina and plundered the people of Bjarmeland or Permia. The most important event in yoking history on the east side of the Baltic happened in 862. The Slav (perhaps rather Germanic Russi) tribes who dwelt south of Lake Ladoga as far as the Southern Dvina invited three Scandinavian chiefs (probably from Sweden), brothers, of whom Rurik became the most influential. These three proceeded to the Pomeranian and Livonian shores, and founded an empire on the White Sea. They established themselves at Holmgard (Novgorod) and laid the foundations of the kingdom of Gar- darik, out of which grew the subsequent Russian (q.v.), that was ruled over by Rurik's descendants down to 1598. Simultaneously with this two other Scandinavian chiefs formed the nucleus of another state at Kjömgard (Kieff); and, sailing thence down the Dnieper, they threatened Constantinople, which was only saved by a sudden storm scattering the fleet of the Northmen or Varings (Varangians), as they were called by the Slavic Russians and the Greeks. Three times during the first half of the 10th century these adventurers appeared before the capital of the Eastern empire, and on two occasions (907 and 945) went away carrying with them heavy sums, the victors by peace, the vanquished by their own city from assault. Igor, the son of Rurik, who commanded two of these expeditions, even launched his fleet on the waters of the Caspian, and carried the terror of the Northmen's name among the Mongols and its shores. The expeditions of the Varings gradually ceased after Vladimir introduced Christianity into his dominions in 988. Nevertheless for many years these Scandinavian rulers in Russia surrounded themselves with stout and trusty warriors from the north, their position being strengthened by the authority of the emperors in China. From the end of the 10th century the emperors of Constantinople had, till the fall of the city in 1453, a picked bodyguard of Varangians. The men of the north esteemed it a high honour to have served in this chosen cohort at Myklegaard (i.e. 'the Great City'); and doubtless they carried back to their countrymen at home many elements or traits of the civilised refinement of the Byzantine court. After the Norman Conquest the Normans, the descendants of the Nor- men, made their way to Constantinople and enshrined in the Varangian guard; these were the only men whose battle-axes cost Robert Guiscard and his Normans trouble at the great battle of Dyrrhachium (1067).

For the language, see ICELANDIC; and see also Scandinavian Mythology.

North Sea. The North Sea, or German Ocean, is a southern extension of the Arctic Ocean (q.v.). It is an almost circular communication between the North Atlantic Ocean lying between Iceland and Norway which has received the name of the Norwegian Sea. Its northern boundary would be represented by a line drawn from the Shetland Islands to the opposite coast of Novgorod and its southern end at the Strait of Dover; on the west it is bounded by the east coast of Great Britain, and on the east by the coasts of Norway, Denmark, Germany, Holland, and Belgium. With the North Atlantic Ocean it has communication through the Strait of Dover and the English Channel on the south, and on the north by the Pentland Firth and the channel between the Orkney and Shetland Islands; with the Arctic Ocean as already stated; and with the Baltic by the Skagerrack and Cattegat. The North Sea is over 600 miles in length and about 260 miles wide, and its area is estimated at over 160,000 sq. m. By far the greater proportion of this area is less than 100 fathoms in depth, the only part where deeper water is found being off the coast of Norway (the Norwegian Gully or Norwegian Deep, as it has been called), where a depth of 360 fathoms has been recorded; the mean depth of the whole area is estimated at 61 fathoms. The sea is very shallow towards the south and east, and the coasts in this direction are low and flat, being in some places below the level of the sea, whereas to the north and west, where the water is deeper, the seacoast is high, and the deep Norwegian Gully is faced by the high and bold cliffs of Norway. The sea-bottom is very irregular, a number of banks running across from the Yorkshire coast towards the Skagerrack, the most important of which is the Dogger Bank (q.v.), and there are also depressions like the Silver Pit; off the low-lying coasts of Holland, Belgium, and Britain there are numerous shoals and sandbanks formed of the materials brought down by the rivers. The North Sea is surrounded by sand and gravel land and receives the waters of numerous rivers, the principal of which are the Thames, Ouse, Humber, Tyne, Tweed, Forth, and Tay, the Scheldt, Rhine, Weser, and Elbe. The deposits forming on the bottom consist for the most part of sand and gravel and in the deeper water of mud and clays,
NORTH SEA

containing stones and fragments of rocks and minerals derived from the land, along with calcareous ooze and peat. This is generally referred to as "silt." The salinity of the water of the North Sea varies between 1°25 and 1°075, the lightest water occurring in the southern part and in the Skagerrack, where fresh water comes from the Baltic, and the densest water at the bottom in the deep water off Norway. The mean depth of the North Sea is 50 miles and over the North Sea in summer is about 66° F., and in winter about 36°, the range throughout the year being about 34°—from 31° to 65° F. Except in the summer months, the temperature of the surface water is higher than that of the air, the mean temperature during the month of January being about 38°, and in winter about 42° F. The winds are variable over the North Sea, the most prevalent being from the south-west, and the currents are chiefly dependent on the direction of the wind; fogs, mists, and rain occur at all seasons. The great tidal flow of the Atlantic advancing from the west is divided into two portions on striking the British Islands: the one entering the North Sea round the Orkneys and through the Pentland Firth, the other coming up the English Channel. Captain R. N. has noticed that the tides in the North Sea, says: 'The former undulation seems to run along the east coast of Britain like a wave along a breakwater, and makes it successively high-water along the coast from Dunvegan Bay Head to Orfordness; the latter undulations run along the coasts of France, Belgium, Germany, &c., and finally ends at the Scaw. As the distance from the coast increases, the rise and fall seems to diminish until it is probable that in the centre of the sea there is very little if any. Captain Hewitt found one spot midway between the British and Dutch coasts where there was no rise and fall. The tidal streams do not depend on the times of high and low water at the different ports, but seem to be more dependent on the position where the maximum rise and fall takes place, running towards that spot when the tide is rising. To divert the tides from St. Abb's Head to the Wash the stream is always running to the southward when the tide is rising in the Wash and to the northward when falling there. From Cromer to the Downs the tide is always flowing against the undulation from the Channel, and the two undulations seem to pass through each other; but there is a very curious fact in connection with the tides viz. all the light vessels in the North Sea affected by the Channel tide rotate with the hands of a clock, and all affected by the tide round the Orkneys rotate against the hands of a clock.'

The North Sea has been from the earliest times one of the most important highways of the world, and is surrounded by some of the most prosperous commercial nations, famous for their maritime enterprise and commerce. The fisheries and agriculture are among the most important in the world, providing employment for thousands of fishermen from the surrounding countries; all the varieties of food-fishes abound, as well as edible molluses and crustaceans, such as oysters, mussels, lobsters, crabs, and shrimps. The value of these fisheries depends to a great extent upon the abundance of the fauna and flora living on the sea-floor, all the various groups of invertebrates being met with in great profusion in the North Sea, whilst the surface water swarm with algae, such as perno, etc., which sometimes form extensive floating banks.

See North Sea Pilot and Admiralty publications; also "Expedition zur physikalisch-chemischen und historischen Untersuchung der Nordsee im Sommer 1872" (Berlin, 1876).

NORTHUMBERLAND

The northernmost county of England, separated from the Lowlands of Scotland by the Cheviots, is bordered by the Tyne and Derwent. The German Ocean bounds it on the east, and the county of Cumberland, with a part of Roxburghshire, on the west. Amongst the English counties it ranks fifth in regard to size, having an area of 1,390,312 acres. Its greatest length is 47 miles, and it is bounded on the north-west by Durham. The surface of the county, except near the coast, is picturesquely broken into rounded and conical-shaped hills and high moorland ridges. The main valleys are fertile and well wooded. The principal height is the Cheviot Hills (q.v.), and are situated on the north-west of this county. These are Cheviot (2676 feet), Hedgehope (2348 feet), Cushtlaw (2200 feet), Bloody Bush Edge (2001 feet), and Windy Gyle (1863 feet). The Simonside Hills near Rothbury attain a height of 1447 feet. The chief rivers are the Tyne (formed by the confluence of two streams, the North and South Tyne, a little above Hexham), the Wansbeck, the Coquet, the Aln, the Breamish, the Till, and the Tweed. In the south-west of the county are some small sheets of water called the Northumbrian Lakes, the lakes of the county are 250 acres. Off the coast lie a few islands—Lindisfarne or Holy Island, the Farne Islands, and Coquet Isle. The geology of the county is simple in its broad features. The beds as a whole slope to the sea, the direction of the general dip lying between south-east and east; hence the oldest rocks—the Silurian in the north-west, near the head of the Rede and Coquet, and the later formations—the Triassic and Permian beds and the coal-measures near the coast. The strata have been dislocated and broken by volcanic disturbances, during which were included the igneous formations. The Cheviots, which cover an area of 200 sq. m., owe their origin to the earlier of these upheavals. They consist chiefly ofandesites and porphyrites. The Whin Sill, a great sheet of basalt stretching across the county from Kylie near Berwick to Greenhead in Cumberland in a series of columnar crags, was injected among the sedimentary rocks during the later eruptions which took place, it is supposed, at the close of the Carboniferous period. A number of basalt dykes also cross the county. The coal-measures occupy the south-east part of the county, and the leadmeasures (of the Limestone series or Yoredale rocks) the south-west.

The climate is cold, especially from March to the middle of June, when the prevailing winds are from the east and north-east. The winters, however, are often much milder than they are in the south. The average rainfall, too, except in the Cheviot district, is considerably less than in the counties of Devon, Dorset, Hampshire, and Sussex. Northumberland contains 541 civil parishes, and, ecclesiastically, is in the province of York. For the purposes of civil government the county is divided into nine districts (ranging from hundreds to wapentakes), three of which formed part of Durham till 1844. It comprises four parliamentary divisions—the Tynedale, Wansbeck, Hexham, and Berwick-upon-Tweed, returning four members. The principal towns are: Newcastle-upon-Tyne, Hexham, Morpeth, and North Shields. Newcastle-upon-Tyne (q.v.) is a city and county of itself. A large portion of the county is agricultural, especially the fertile tracts along the principal valleys and near the coast. The usual rotation of crops is oats, turnips, and a small quantity of grass. The cattle consists of whees, or Skye, cows, and other breeds, and there are also sheep. The forests, mostly fir and混 and other grasses, and then pasture. Turnips grow well, the cultivation of them on raised ridges being peculiar to the county, and known as the Northumbrian system. The western portion of the county is pastoral, the slopes of the Cheviots.
affording sustenance to large flocks of hardy sheep. In Chillingham Park there is preserved a herd of wild cattle said to be of the original British stock. The staple trade of the county is in coal, and the chief manufactures are connected with its mining and engineering industries. The population of the county is about 114. The salmon-fisheries of the Tyne and Tweed have long been famous. The county is traversed by the North-Eastern and North British railways. Pop. (1801) 168,078; (1841) 206,020; (1851) 222,362; (1861) 206,039.

The name Norton, when the Roman province of the same name, included the county, was derived from the Latin word nortus, or the Norse word nors, meaning northern. It was the northern limit of the Roman province, which was bounded to the south by the river Tyne, and to the north by the North Sea.

Northumbria, the most northerly of the ancient English kingdoms, stretching from the Humber northwards to the Firth of Forth, and separated westwards from Mercia and Lindsey by the Derwent and Trent, from the Pennine range and the Ettrick Forest. Bernicia, the district north of the Tees, had for its first king Ida (547-559), who built Bamburgh as his capital. His grandson, Ethelfrith, mounted the throne in 593, and having married the daughter of Ella, who in 594 had formed the kingdom of Deira out of the district between the Tees and the Humber, set aside the rights of his boy brother-in-law Edwin, and so united both Bernicia and Deira into one kingdom. But the ousted Edwin, returning in 616, conducted himself with great energy, and himself became king of the Northumbrians as well as Bretwalda. Under him Northumbria was Christianised. In 633 he fell in battle against Penda of Mercia and the Welsh Cadwallon, but a year later St Oswal, son of Ethelfrith, cleared the country of the Mercian invaders, and wandered under his rule. His brother and successor, Oswy, was forced to yield Deira to Oswin, son of Osric, his cousin, but in 634, by a great victory in which Penda perished, was able anew to unite his kingdom, and reigned till 657, the most powerful of all Northumbrian kings. Under King Egfrid (657-696), Aldfrid (685-705), a great patron of learning, and as many as fourteen obscure successors, most of whom came to a violent end—

Northumbrian influence gave way before the rise of Mercia, internal tumults, and Danish ravages, until 896, when the chroniclers cease to give a regular succession of kings, and 877, when at length Northumbria became tributary to Egbert. See the History of the English Church and People. South of the river Tyne the county is divided into Sir Robert's district, and in some respects has separate institutions. The province, which constitutes the great part of Hindustan proper, is mainly a great alluvial plain, sloping from the Himalayas, and comprises the Dudd, Rohilkhand, Bundelkhand, and the Upper Ganges valley. It is the great wheat country of India, but is not on a level with Bengal as to resources or trade. The headquarters of Hinduism, and containing some of the most sacred memorials of the Aryan race, it was nevertheless long subject to Moslem sway; and in 1851 13'4 per cent. of the population consisted of Moslems, as compared with 86'3 per cent. Hindus. The divisions of the North-western provinces are Meerut, Agra, Rohilkhand, Allahabad, Benares, Jhansi, Kunnon, and the four divisions of Oudh—Lucknow, Sitapur, Fyzabad, and Hardwar (1870). The area under direct British administration (with Oudh), 167,938 sq. m.; pop. (1891) 46,905,683.

The native states have a further area of 5109 sq. m., and a pop. (1891) of 729,491. With the native states the area is about the size of Italy, and the population a half larger than that of Italy. Even with the Himalayan districts, the population is much denser than England and Wales. The capital is Allahabad. See INDIA, OUDI.

North-west Passage, a route for ships from the Atlantic to the Pacific by the north of America. The North-west Passage is that by the north of Asia. See POLAR EXPLORATION, ARCTIC OCEAN, FRANKLIN (SIR JOHN), NORDENSKJOELD.

Northwich, a market-town of Cheshire, on the river Weaver and the old Watling Street, now completed by the Chester-Manchester railway. The town and all round it are great numbers of brine-springs, which have been used for the preparation of salt since before the Christian era. The town is being gradually undermined by the pumping of the brine, and the cavities so formed have caused many houses and buildings to fall. Several of those that still stand are propped up or bolted together. The streets are narrow and irregular, and many of the dwelling-houses are of an antique type. In 1670 rock-salt mines began to be worked, and now great quantities of this mineral are extracted. The town was taken by the parliamentarians in 1643. Pop. (1881) 12,246; (1891) 14,914.

Norton, Andrews, American theologian, was born at Hingham, Massachusetts, December 31, 1786, graduated at Harvard in 1804, was appointed mathematician of the United States Navy in 1806, librarian of the university and lecturer on biblical criticism and interpretation. In 1819-39 he was Dexter professor of Sacred Literature. Norton was among the most distinguished exponents of Unitarianism, equally determined in his protest against Calvinism and in his devotion to the school of Theodore Parker and the naturalistic theology. His chief writings are Reasons for not believing the Doctrines of Trinitarians (1833), and
NORTON

NORWAY

Norton, the Hon. Mrs. Caroline Sheridan, poet and novelist, and granddaughter of Richard Brinsley Sheridan, was born in 1808. In 1827 she married the Hon. George Chapple Norton (1800-75), the second of their three sons, Thomas Brinsley (1822-77), became the fourth Lord Granville. Their marriage was most unhappy, and her friendship with Lord Melbourne led her husband to institute (1836) a groundless and unsuccessful action of divorce, the damages laid at £10,000. Already she had made her pen £1400 in one year, and after her husband had separated she continued her literary activity. Her poems include The Sorrows of Rosaline (1829), The Undying One (the Wandering Jew, 1830), The Child of the Islands (1845), and The Lady of L Georgetown (1802); her novels, Stuart of Dunbarton (1847), Lost and Saved (1863), and Old Sir Douglas (1868). In March 1877 she married Sir William Stirling-Maxwell (q.v.), but died on the 15th June following. Her story beyond doubt supplied the subject for Diana of the Crossways, the most charming of George Meredith's novels.

Norwalk, (1) a city and township of Connecticut, at the mouth of a river of the same name, on Long Island Sound, 41 miles by rail NE. of New York. There is a good harbour, and extensive oyster-fisheries. Norwalk possesses the largest straw-hat factory in America, and within the township are many manufactories of felt-hats and cloth, woollens, shirts, shoes, locks, and0 knobs, besides foundries and ironworks: several of these establishments are in South Norwalk, Pop. of Norwalk (1900) 6215; South Norwalk, 6591; township, 16,932. (2) Capital of Huron county, Ohio, latitude 43° 53' N., longitude 83° W., of Cleveland. It is a pleasant little city, with streets shaded with maples, and manufactures organs, shoes, ploughs, sewing-machines, tobacco, and fanning-mills. Pop. (1900) 7074.

Norway (Norweg., Norge), the western division of the Scandinavian peninsula, extends from lat. 57° 56' N. (Lindesnes) in the south to 71° 11' in the north-east, overlapping Sweden and Lapland on the N. and screening them from the Arctic Ocean. Although 1160 miles in length (coast-line 3000 miles), it varies in width from 29 to 100 miles north of 63° N. lat.; below that line it well out to a chil-shaped mass 260 miles in width. It is separated from Sweden by the Kjolern (i.e. Keel) Mountains (3000 to 6000 feet), the backbone of the peninsula, which run parallel to the Norwegian coast from the plateau of Finnmark in the north to 63° in the south, and then towards the east. The main range trends north-westwards, still marking the boundary between the two sister kingdoms, though it decreases greatly in height. The other division continues parallel to the coast, in a south-westerly and then southerly direction, to the extremity of the country. But

the mountains in this division no longer form a narrow ridge or "keel"; they widen out into a broad plateau, undulating between 2000 and 4000 feet and embounded with mountains, of Charles Eliot Norton and Dr Ezra Abbot.—Charles Eliot Norton was born at Cambridge, Mass., 16th November 1827, and graduated at Harvard in 1840. He travelled in India and Europe at times between 1840 and 1848. He was an editor with Longfellow, Lowell of the North American Review. In 1874-77 he was professor of Art History at Harvard. He received in 1884 the degree of LL.D. from Cambridge University, and in 1887 that of LL.D. from Harvard. He published a translation of Dante, &c., edited the Correspondence of Carlyle with Emerson and Emerson's letters of farewell to Lowell, and is literary executor in America for Ruskin.

Norton, The Hon. Mrs. Caroline Sheridan, poet and novelist, and granddaughter of Richard Brinsley Sheridan, was born in 1808. In 1827 she married the Hon. George Chapple Norton (1800-75), the second of their three sons, Thomas Brinsley (1822-77), became the fourth Lord Granville. Their marriage was most unhappy, and her friendship with Lord Melbourne led her husband to institute (1836) a groundless and unsuccessful action of divorce, the damages laid at £10,000. Already she had made her pen £1400 in one year, and after her husband had separated she continued her literary activity. The other division continues parallel to the coast, in a south-westerly and then southerly direction, to the extremity of the country. But
port towns. The density of the population over the entire surface without special grown towns, is much the lowest of any country in Europe; but then fully 70 per cent. of the total area is wholly uncultivable, being barren mountain and waste (2 per cent. under glaciers); in addition 24 per cent. is covered with forest. The table shows the area and population of the districts.

Finmark, which is inhabited chiefly by Lapps, about 18,000 in number, whom the Norwegians call Lemmings, is deeply intersected by rivers and Fins they call Kvens, is a monotonous undulating plateau (1000 to 2000 feet). The coast is deeply indented with large fjords (Varanger, Tana, Laxe, Porsanger, Alten), and east of the North Cape (q.v.), is low, bare, and bleak, though the banks of Pasvig, the frontier river with Russia, are cultivated, and produce vigil's produce, of iron, pine, and birches. Vegetables, barley, and peas ripen on the shores of the fjords, thanks to the Gulf Stream and the eight weeks of uninterrupted sunlight that prevails in summer. At that season too, is the short, to be a terrible plague to man and beast. The cliffs and islands swarm with wild-fowl, and the sea-fishes with fish. The wolf and glutton are common, the former being a dangerous enemy to the Lapps' reindeer herds. West of 23° E. long. the coast breaks rocky, wild, and almost uninhabited; it is, however, irregular in the extreme; and these characteristics are especially pressed right down to below 59° N. lat., to the point nearest Scotland (290 miles distant). From this point up to the North Cape the entire coast is protected from the Atlantic waves by a belt of rocky islands, called the Saltstraumen, which vary in many parts between and the coast there are connected navigable roads, sheltered and safe at nearly all seasons. The outermost islands of this belt are the Lofoten and Vesteraalen chains; in both groups the mountains (2000 to 3000 feet) rise in extremely fantastic pinnacles and spurs, with razor-backed pinnacles and gabled roofs. But wherever, on these and all the other islands of the Skjærgaard, there are level patches and level soil of the beach by the modifying climatic influences grass grows abundantly. The climate is continental, mild that rye and barley easily ripen, and large flocks of sheep are left out all winter, whilst from 27,000 to 31,000 fishermen congregate here in the winter to prosecute the herring and cod fisheries. All the islands of the Skjærgaard are frequented by enormous quantities of sea birds, especially duck and gull varieties; they are "fowled" for the sake of their down (from the eider duck), feathers, flesh, and oil. On some of the islands the red deer still chapters. On the mainland the mountains in the north have some bare, angular outlines as in the Lofoten, but support in many parts large forests of fir and pine; in southern Norway they have rounded, domed-summits, and are, next the sea, only sparingly covered with fir (nor-pine) and other trees. The peninsular rampart is crowned with several gigantic glaciers—e.g. the shores (6000 feet) of Lyngen Fjord in the north are lined with them; from Jokel Field, an arm of the Kvenang Fjord, large masses of ice drop off the glaciers into the sea, and in front of this field just north of 67° N. lat. is the enormous snowfield of Sulitjelma (6108 feet), and just south of the same parallel Svarstein (3000 feet), the second largest glacier in Norway, measuring 44 miles by 12 to 25, and sending down glacier curtains to within a few feet of the coast. The western part of Norway possesses the second largest glacier in Europe (Vatnajökull in Iceland being the largest), the roof-shaped Jistad (4000 to 5400 feet), which has an area of 380 sq. m. (87 miles long by 6 to 22 miles wide), and reaches down its icy pelycous arms to within 150 feet of the sea; to the south of it lies the snowfield of Folgefond, 40 miles long and 7 to 15 wide (108 sq. m.), and 3000 to 5000 feet in altitude. Throughout Norway the limit of perpetual snow ranges from 3100 feet on Jistad to 5140 on the Jotunbalde. The lofty west coast region is everywhere cleft with gigantic fissures, very narrow and winding, into which the sea-water flows—the fjords. In some cases they are of great depth, much deeper than the sea outside (200 fathoms); Sogne Fjord, for instance, is 200 fathoms deep at the close of the fjord, and reaches down its icy pelycous arms to within 150 feet of the sea; to the south of it lies the snowfield of Folgefond, 40 miles long and 7 to 15 wide (108 sq. m.), and 3000 to 5000 feet in altitude. Throughout Norway the limit of perpetual snow ranges from 3100 feet on Jistad to 5140 on the Jotunbalde. The lofty west coast region is everywhere cleft with gigantic fissures, very narrow and winding, into which the sea-water flows—the fjords. Throughout Norway the limit of perpetual snow ranges from 3100 feet on Jistad to 5140 on the Jotunbalde.
its tributary the Hallingdal (113), Numedal, Laagen (143), and Otteren (140). Some of these streams in their lower courses expand into long narrow lakes of considerable size: Lake Mjøsa is 60 miles long, and its bottom is 1080 feet below the level of the sea; others are Hardanger Fjord (60 miles long, 19 miles wide), and Finnmark (35 miles long and 2900 feet above sea-level). The slopes of these valleys, especially in the southern and eastern parts of the country, are planted for miles upon miles with forests, chiefly fir. In these forest regions the elk is still found, and occasionally the hazel-grouse abound. The trees are felled principally in winter, and floated down the streams in early spring to the sawmills at their mouths.

Geology.—The great mass of the Norwegian plateau consists almost entirely of Archean rocks, chiefly granite and gneiss, with quartz and hornblende schists in a subordinate degree, in very many cases clearly stratified. In central and western Norway (the field region) the primary rocks are covered with layers of metamorphosed clay-slate and quartzite, whilst large masses of eruptive rocks of granite, gabbro, and diabase are also found, especially in the Jotun Tandel. Porphyry, greenstone, labradorite, serpentine, have pierced through both formations and overspread them in broad sheets or coverlets. The prevailing formation in eastern Norway is called Sprangmitte, a series of conglomerates and breccias, sandstone and quartz. Bands of Silurian rocks extend across the southern part of the country from south-west to north-east, the two most clearly-defined belts stretching from Hardanger Fjord to Tromsø and from Aalen Fjord between the coast to Lake Moss. Most of the rocks of the plateau have been greatly crumpled, folded, twisted, crushed, and displaced. The prevailing formation throughout northern Norway is granite. Nearly all parts of the country bear conspicuous traces of the scratching, grinding, and polishing to which the structural rocks were subjected during the Glacial age and the period of its departure. Incised and striated lines, and polished surfaces, occur at all altitudes up to 5000 feet, and generally follow directions radiating outwards from the highest mountain-knots to the peninsulas. The gneiss, granite, and sandstone, the surface of the country nearly everywhere; moraines are numerous, and transverse ridges of glacial detritus block the mouths of many of the valleys; 'giant kettles,' the basins that received the glacial cataracts, occur in numerous districts near the sea. Moreover, the lines of ancient beaches, whether of the ocean or of glacial lakes, are distinctly traceable at many points along the coast from Bergen to the North Cape; sometimes there are two, or even more, one above another.

The coast of northern Norway is estimated by some authorities to have risen between 400 and 600 feet. See UPLIFTAL AND SUBSIDENCE.

Industries and Occupations.—Norway's natural wealth lies in her fisheries, her forests, and her shipping; her manufactures, her mines, and her agriculture are all unable to meet the home demands.

By far the most important of the fisheries are the cod and herring. Cod are taken by 80,000 to 90,000 men on the west coast from January to April. They are caught chiefly in two ways, being either dried on wooden frames (hence called torfisk = 'torf fish') or split by sawyers, called toftblikk or 'split fish'. The former are exported to Italy to the average annual value of £374,000, the latter to Spain to an average ranging from £289,000 to £338,000 a year. Besides, cod-liver oil is exported to an annual average of £393,000, salted roe to £289,000, and heads and offals, powdered for manure, to £37,000 to £63,000. Herrings are taken all the year round and exported to an annual value varying from £575,000 to £639,000. Mackerel (£583,300) and oysters are taken off the south coast, whelks off Kongsfjord, and lobsters (£26,200) off the west coast. Off the north coast of Finnmark cod, saithe, flounders, smelt, &c., are taken in summer and bartered to Russian merchants for flour; this fishery engages about 15,000 men.

The fishery in the Polar seas for whales, walrus, seal, dog-fish, sharks, &c., is prosecuted by about 1600 men in less than 100 small vessels, sailing from Tromsø and Hammerfest, with a few from Vardø; their total earnings in a season vary between £175,000 and £195,000.

The inland lakes and rivers contain an abundance of salmon, trout, and red char, and some of the southern lakes have also grayling, brown, perch, and pike.

The forests cover about 24 per cent. of the entire surface, though the area has been of late years very greatly diminished. Trees are, however, being re-established, and the forests (340 in number) give employment to 10,300 men, whilst 1600 more are engaged in the preparation of wood-pulp and cellulose (42 factories in 1885). Timber of all kinds is exported to a total value of £1,785,000 (1888; £2,111,000 in 1890). Timber pauper-pulp and cellulose factories, increased from £130,300 in 1880), matches to £97,400, and articles manufactured from wood to £231,600.

Agriculture is carried on chiefly in the vicinity of Christiania, the lower ends of the eastland valleys, in the level district of Jædersen in the extreme south-west, and around Trondhjem. The farms are mostly small; 94 per cent. of the entire number measure less than 50 acres each, and more than half the farmers own the land they cultivate. Of the total population 53 per cent. are engaged in or connected with agriculture. The rearing of cattle, sheep, and goats—in the north reindeer—are important branches. The area under cultivation is only 2 per cent. of the entire surface of the country, and meadows and grazing land add another 23 per cent.

A century ago and down to about 1870 the copper and iron mines of Røros and the silver-mines of Kongsberg yielded considerable outputs; but they have since greatly declined. The only vigorous mine is at Vegnas (on Karmø, at the entrance to Bakken Fjord), which yields £61,000 worth of pyrites in the year. The total mineral output of Norway (iron pyrites, silver, copper, apatite, nickel) was worth £191,300 in 1885, one-half the value of 1882. The silver mined is, however, still worth £57,700 a year. Barely 2000 men are employed in this occupation.

The purely industrial establishments are grouped mainly around Christiania, and only 45,000 people altogether. Besides those already mentioned, the more important are textile manufactures (6057 employees and 143 factories), machine-shops (4282 men in 30 establishments), chemical factories (75 with 3062 men), iron and metal works (67 with 2831 men), brickworks (105 with 2334 men), flour-mills (387 with 1787 men), tobacco-factories (43; 1677), breweries (47; 1411), and in a minor degree tanneries, distilleries, and factories for matches, glass, oil (fish and vegetable), and paper. Water is the favourite motive power, only 200 out of 2900 establishments using steam.

The Norwegians rank amongst the busiest seacarriers of the world, close upon nine million tons of merchandise being carried annually in Norwegian vessels, in all parts of the world, the owners of which earn the aggregate sum of
about £6,000,000. Yet the mercantile marine of Norway only embraces (1893) a total of 3528 sailing-vessels of 1,255,329 tons and 454 steam-vessels of 241,419 tons. But, as in nearly all other countries, steam-vessels are supplanting sailing-vessels. Ship-building in the kingdom is increasing. In 1884, with the employment of 2000 men, and situated chiefly in the south, the principal seat of this industry being at Christiania. Sails are made by 1000 men in over fifty workshops. The coast fishermen use for the most part heavily-built wooden vessels, of small tonnage, especially in the northern waters.

The ports of Norway were enterled in 1895 (an average year) by 11,551 vessels, having an aggregate tonnage of 2,846,943, of which 63 per cent. entered under the Norwegian flag and 16 per cent. under the British. The exports in 1894 had a total value of £7,268,447 (more than in 1883); the imports, of £11,373,090 (less than in 1883). The exports during the ten years ending 1888 ranged between £4,857,000 (1879) and £6,381,000 (1882) in value; the imports, between £7,348,000 (1879) and £9,167,000 (1881). The bulk of the Norwegian whaling business is carried on in the Arctic sea. The imports of foreign vessels and receiving 32½ per cent. of the imports. Germany comes next with 27 per cent. of the imports and 14 per cent. of the exports, and Sweden third, with 13 and 13½ per cent. respectively. The principal articles of import are fish (rags included), and Swedish, or tallow, and Belgian wax (altogether £1,595,000 in 1888), textiles (£1,527,600), bacon, butter, and other provisions (£7,800), iron and other metals, raw and manufactured (British £186,300), coffee (£564,600), coal (£473,000), ships (£298,800), sugar and molasses (£265,000), timbers from Sweden, tobacco (£234,900), the milk and glycerine (£286,400), hides (£224,000), wines and spirits (£173,100), and smaller quantities of salt, tobacco, fruits and vegetables, paper, &c.

The more important of the exports are fish (£2,559,400 in all) in 1888), timber, &c., (£2,415,600), minerals and metal-ware (£414,100), tallow, tar, &c., (£342,900), hides, Bornes, &c., (£312,400), textiles (£197,400), and paper and dyestuffs. In addition, mectone, and timber to the total value of £318,100 pass out of the country in transit. Close trade relations with the Scandinavian countries and the foreign trade passes through the three principal ports of Christiania (38½ per cent.), Bergen (17½ per cent.), and Trondhjem (7½ per cent.).

People.—The Norwegians share with the Swiss the honour of being the most democratic people in Europe. The people are proud of their freedom and independence, and regard the state regulations imposed on them as a burden. To the franchise are granted all those who have paid the poll-tax. In 1885 the total number of children born 8-25 per cent. were illegitimate; the figure stands in England at 4½; in Scotland, 8½; in Ireland, 29.

Since 1871 earnest endeavours have been made to diminish the consumption of spirited liquors, the instrument chiefly relied upon being the Gothenburg licensing system. This system was by 1888 established in all but three out of the fifty-four counties of Norway. The chief causes of the rapid growth of the population, the consumption of spirited liquors decreased from £2,698,960 gallons in 1876 to 1,325,060 gallons in 1888, a reduction of more than one-half. Moreover, after paying expenses, granting 5 per cent. to the shareholders are the vast profits derived from the sale of spirits and from whom the system supplants, there remains an annual surplus of £42,800 to £55,500, which is spent in the maintenance of schools, public roads and links, water-works, poor-relief, and charitable institutions. As road-makers the Norwegians vie with the Swiss; their difficult country less compelled them to perform some feats of engineering skill of no mean order. But the principal means of communication are steam-boats, which ply all along the coast, on the fjords, and the inland lakes. There are, however, some 15,000 miles of well-kept national and communal roads, and 970 miles of railway (all but 42 miles managed by the state), and close upon 5000 miles of telegraph lines (not wires). The railway lines radiate chiefly from Christiania. One connects Trondhjem with the capital, and Paris in 36 hours; another is building to connect Norway with Sweden. Norway is now visited every summer by great numbers of tourists; the number increased from 13,569 in 1886 to 23,403 in 1890, one-third being British, the rest chiefly Swedes, Danes, and Germans.

The people and the government are well educated and intelligent. Attendance at school is free, and compulsory upon all children between seven (six and a half in towns) and fourteen. The country is well equipped with primary schools, and for the higher branches there are fifty-four middle-class schools, seventeen lyceums, and the university of Christiania, with five faculties, and (in 1893) 1290 students and fifty-four lecturers. In addition there are numerous excellent private schools. The state contributes about one-third of the total cost of the public education, the remainder being provided throughout the country. Except for about 4000 persons, the entire population belong to the Lutheran Church. For purposes of ecclesiastical government the country is divided into six dioceses (stift), each administered by a bishop—viz., Christiania, Hamar, Christiania-Norway, Bremen, Falck, and Trondheim. Constitution.—Norway is a free, independent state, nominally a kingdom, but practically to all intents and purposes a republic. The supreme executive rests with the king, who is at the same time king of Sweden; but the responsibility for his acts is borne by a council of state, appointed by himself from Norwegians above thirty years of age, and consisting of two ministers and at least seven councillors. One minister and two councillors must always be in attendance on the king when he is not in Norway. The other minister and the remaining four councillors being appointed by himself, and the minister presiding over the deliberations of the council (sometimes also taking a portfolio), and the councillors directing each a special department—at present seven, Religion and Education, Justice, Interior, Finances, War, Defence, and Miscellaneous Public Accounts. As viceroy in Norway the king may appoint his eldest son, or his eldest son, but none other; if there is a viceroy, he presides over the council of state. The king declares war and peace, and makes treaties and alliances in his own name. He organises and maintains the army and fleet for an aggressive war without the consent of the Norwegian parliament. Both countries are represented by one and the same
diplomatic corps. The people participate in the government through the Storting or parliament, which consists of 114 members, 76 representing the country districts and 38 the towns. All Norwegians above twenty-five years of age who satisfy certain conditions of residence and property qualification, or station, meet once in every three years in the parish church and choose one man from every hundred of their number to select the members of parliament for the county. Every man so selected, even though it be against his will, is obliged to sit in one parliament (of three years), but not in a second. If a sitting member dies his place is not filled, but the next on the list of representatives selected by the electors. As soon as the Storting meets (in February every year in Christiania) one-fourth (20) of the assembled members are chosen to form an upper house (Lagthiing); the remainder constitute the lower house (Hidstding), in which all legislative measures are proposed either by a member of the house or by a member of the government. The upper house may send back a bill twice; but after the second rejection both houses vote together as one, though in that case a majority of two-thirds is necessary. The king's signature is required for the bill. But if he refuses to sign, and the bill is passed by three successive parliaments (not sessions), it becomes law in spite of the king's veto. Every member of the parliament is allowed 13s. 4d. a day with travelling expenses. The affairs of each county and borough are managed by a county commissioner, who is also a member of the national legislature. Both the counties and the communes enjoy a liberal degree of self-government. Justice is administered locally by sheriffs. Of late relations with Sweden have been strained in various departments, and Norway has demanded representatives, men and material, in the national fleet. The national revenue increased in ten years from about £2,500,000 to £3,702,380 (1897–98), and the expenditure, which in 1890–94 exceeded slightly the revenue, was more than covered by it in 1895 and following years. The debt just touched on £20,000,000 in 1897. The monetary unit is the krone (1s. 14d.), divided into 100 ore. The metric system of weights and measures prevails; and Norway has her own national flag distinct from Sweden. The national defences embrace an army and navy. The army has its headquarters at Trondhjem, and the navy at Christiania. The national fleet consists of the aircrafts (first and second class), four ironclad monitors, and some thirty other vessels, with a torpedo service.

See Kier, Norges Land og Folk (1886); Kirchhoff, Lænderkundt (14. ii. 1890); in English, see Da Chaillu, Land of the Midnight Sun (2 vols. 1881); F. Vincent, Norsk, Lapp, and Finn (1881); Mary Godwin, Letters from Norway (1882); J. D. Fadiman, Norge og Glaciater (1853); and numerous modern books of travel, such as C. W. Wood, Round about Norway (1889); Lovett, Norwegian Pictures (1885); Coming, From Arpad to Ptolema (1889), and others. But the geology see Kjerulf, various works in Norwegian (1855–79); for the plant-life, Schübler, Norges Værstige (3 vols. 1888–90); and other works; and for the statistics, the public reports of federal and local governments, partly duplicated in French. The best guidebooks to the country are those by Yngvar Nielsen, Daedeker, Tønsberg, Bennett, Jørgensen, and Wilson.

History.—It is not until the 9th century that the story of Norway begins to emerge from the obscurities of myth and legend. At the time the tribes of Gothic descent crossed the Baltic and settled in the southern parts of the Scandinavian peninsula they found the Lapps or Finns in possession. These people they drove north towards the Arctic Ocean. When this immigration took place cannot be determined exactly. Indeed, as according to one theory, the original home of the Aryans was in Scandinavia, it probably never took place at all. At the dawn of the historical period Norway was parcelled out among the free men of the three main islands. The two north, Norway and the West, were inhabited by slaves—prisoners taken in war—tillled the soil, whilst they and their free dependents spent their time in fighting, Viking raids, and similar pursuits. The ties that united these free men were personal rather than political or territorial, though for judicial purposes all who dwelt in a well-defined district (fyldski) met at stated intervals and at fixed places to adjudicate in common, on terms of strict equality. Several of these districts were associated together in a higher unity—the thing. Of such things or meetings there came to be eventually three, which regarded the north, the west and south, and the Edsfiö for the east; at a later date the Borgar thing for the south-east was separated from the Edsfiö. Each of these things had its own independent code of purely customary laws. The chief men, calling themselves kings, after years (ears) of roaring, as time went on, had power was due solely to their personal influence— their character, wealth, warlike renown, and long descent (compare NORMEN). The cradle of the future kingdom of Norway was the district of Vestfold, on the western side of Vik (now Carlsvær, Fredvang, &c.). Here the Goths of Sweden established themselves, seemingly in the 7th century. A descendant of these kings, Black Halvdan (died 860), reduced the petty kings to the north of him, as far as Lake Mjosen. His greater son, Harold Harfanger or Fairhair (king 863–890), extended his sway as far north as Tromsö, in which district, as being his first conquest in lands that owed no allegiance to the chief king in Sweden, he established the seat of his power, just as the elector of Brandenburg called himself Frederick I, king of Prussia. Through some of his later sons, the last near Stavanger, in 883, he conquered the kings of the west and south-west, and proclaimed himself chief king in Norway. But many of the defeated chiefs (kings) refused to submit to Harold, especially when he asserted the right of conquest, seized their royal lands, and introduced a form of feudalism. They sailed across the Western (North) Sea, and colonised the Faroe, Shetland, and Orkney Islands, the Hebrides, Man, Ireland. But they so harassed the men (jarls) to whom Harold had given their lands in Norway that the king, pursing their enemies, and relieved the islands to his sway, and appointed earls over them (Orkneys, Hebrides). Those who were still dissatisfied escaped his rule by sailing to farther to Ireland. In Harold's reign the skalds or improvisators court-poets began to compose, and their poems were held in great honour, e.g., The Snorre was written in Norway by a younger brother Haco in 935, and for many years the country was distracted by Eirik's sons trying to recover their father's power. After Haco died (961) their principal opponent was Earl Haco of Trondhjem, who ruled over the whole west half until he was killed in a revolt (995). Olaf Tryggeson, a descendant of Harold Harfanger, a man who had won great fame as a Viking in England (961–994) and elsewhere, stepped into the gap. Like his great-uncle Haco, he was a Christian,
and like him he attempted to make his people Christian, and to make them Christian, at least nominally and superficially. The beau-ideal of a sea-king, and the pride and admiration of his people, Olaf died a hero's death, fighting against a host off the north coast of Prussia (1000). After an interval of fifteen years another Olaf, likewise a descendant of Haardraade and Stéphanus Magnus and wedded to the kingdom from the sons of Earl Haco. This Olaf, St. Olaf, made his people's Christianity more real, first thoroughly welded the kingdom into a united state, made all the western islands tributary, and ruled sternly but well. Ever since the days of Harold Haardfage the king of the Danes had claimed supremacy over at least southern Norway; in 1028 the great Canute came with a large fleet to make good his claim. Olaf fled to Russia, and in attempting to win back his crown perished in battle at Stiklestad near Trondheim (1030). Five years later the chief of the clan made Olaf's son Magnus king, and he became king of the Danes also in 1042. But this office he found so difficult that in 1046 he associated with himself as king his uncle Harold Haardrada, who had served in the Varangian guard at Constantinople and lands of the Baltic near Stéphanus. War between the Danes and Norsemen was almost chronic all through the reigns of Magnus and Harold, who became sole king in 1047. Harold's love of adventure led him to his death at Stamford Bridge (1066) in England in the interests of peace and the reign of Harold's successor, Olaf Kyrrre (1067–93), commerce thrived, industrial guilds were formed, and the land prospered greatly. The next king, Olaf's son, Magnus Barefoot, waged war in the Orkneys, Hebrides, and Ireland, till he fell in this last island in 1107. The young Eduard Håkonarson and Sigurd (died 1130), then reigned in concert, Eystein being a quiet stay-at-home prince, whilst Sigurd, who had inherited all the adventurous进来ances of his ancestors, sailed to the Levant, and visited Jerusalem and Constantinople (1167–71). After his return he greatly fostered the church. At this period the towns began to be prosperous. From 1130 to 1240 the country was torn by internal feuds, three predominant parties contesting for power—an oligarchical party amongst the chief men; the bishops' party, who claimed the right to the throne; and the nationalistic Birkebeiner (i.e. 'Birch-legs'), who generally had the first two parties allied against them, but who in the long-run got the victory. After defeating the earls and bishops, and slaying the men-of-war, Margaret of Denmark united all Three northern kingdoms of Norway united, and the crown passed to her son, the young Magnus the Law-betterer (1263–80), who, in 1269, gave up the Hebrides to Scotland. The pretensions of the bishops' party were finally crushed by Erik (died 1299), son of Magnus, and father of the little Margaret, Maid of Norway. Erik's successor, his brother Haco, dying (1319) without a son, the throne passed through a daughter to the Swedish royal house, and again through marriage to the Danish (1380). The great Queen Margaret of Denmark united all three kingdoms by the Union of Kalmar (1397). And now evil days fell upon the land. The extraordinary exertions of Norway's youth seem to have worn her out early: her high spirit and enterprise were gone; her literature died out, and her intelligence burnt down to a dull glimmer; her commerce passed into the tyrannical hands of the Hanseatic merchants of Bremen; her old colonies, Orkney and Shetland and the Faroes, were lost, the Hebrides in 1468; Denmark, which at first respected her national rights, treated her from 1536 as a conquered province, and forced the Reformation upon her, yet the Norwegians never seriously resented the harsh and oppressive treatment of their rulers. In 1612 some 200 men from Scotland, whilst making their way to join the army of Gustavus Adolphus in Sweden, were cut to pieces by the Norwegian peasantry in the pass of Kríndal in Gudbrandsdalen.

The national spirit began to stir again in the awakening of the peoples occasioned by the French Revolution; and the transference of Norway to Sweden in 1814 gave back to the Norwegians their national rights, a liberal constitution, and their sense of national unity. At first they resisted the transference. Prince Christian of Denmark headed the movement for independence, and summoned to parliament, which at Edsvold (17th May) drew up a liberal constitution. But Sweden marched her forces into the country, and on 10th October Christian abdicated. Charles XIII. of Sweden, having recognised the constitution, was elected king of Norway. In 1821 the Norwegians established all titles of nobility. The spirit of independence and of nationality has grown stronger as the years have passed, industry has thrived, commerce has prospered and brought wealth, and, intellectually, Norway stands the last. The union with Sweden was the overwhelming protest of the people against the right claimed by the king to veto absolutely bills duly passed by their elected representatives. The 'home rule' struggle has since 1865 been accentuated. See Munch, Det Norske Folk Historie (7 vols. 1862–65); E. Sars, Norge i middelalderen (1883–87); Keiser, Norges Stati's- og Rettsforfatning (1887). In English, Heimskringla, trans. by W. Morris and Magnusson (vols. iii. - vi. of Saga Library, 1891) or by Laing (3 vols. 1863–73); New Norweg. Dictionary (1878–80); A. W. Jusoyen, Birkebeiner (new ed. 1890). T. Michell, History of the Scottish Expedition to Norway in 1618 (1886); and Powell and Vignous, Corpus Poeticum Boreale (1883). Carlyle's Early Kings of Norway (1873) is adapted from Laing's Heimskringla.

Literature.—Like Germany, Norway has an ancient period, the era of the chief men and the interval between being mostly blank. The ancient period of Norwegian literature is that of the Sagas (see SAGA), and see also ICELAND, SNØRI STURLASON, EDDA. What writers Nor- way gave birth to between the 13th and the 19th century, especially Engelbrekstads (1834–1716), and his contemporaries Engelbrekstadsdatter (1634–1716), are counted amongst the Danes, in whose language they wrote. These men, Holberg, Tullin, Wessel, Fasting, Brun, Frömann, and others—some of them the brightest ornaments of Danish literature—have been already mentioned under the name Dano-Norwegian. The modern period begins with the re-awakening of the national life; it received its first impulses from the Norwegian Society, a band of patriotic men living in Copenhagen in 1775, from the founding of a native university at Christiania in 1811, and from the recovery of national independence in 1814. The earliest writers of the new era, the poets Bjørnegaard (1792–1812), M. C. Hansen (1794–1842), and Schweb (1793–1860), though the ring of patriotism is in their work, possessed little originality. The creator of the modern national literature was Wergeland (1808–45), the Schiller
of his country, who believed that in the free peasant proprietor lay the hope of Norway’s future, and who laboured earnestly to make him worthy of that high calling. The nebulous thought and disregard of aesthetic law and taste shown in his earlier literary attacks of Wellhaven (1807-73), a master of poetic form, and the representative of the intellectual aristocracy of the country, the mercantile and official classes. This gave rise to a keen literary feud. But, apart from Andreas Munch (1811-84), the ladies’ poet, who startled literature with his poems (1813-) and V. W. Jensen (1812-67), and Th. Kjerulf (1825-88), who were more or less influenced by Wellhaven, nearly all subsequent writers have worked in the spirit of Wergeland, and for the same ends. Monsen (1815-52) penned lyrics which sometimes approach the best of Wergeland’s later work in quality. Ansen (born 1813), Vinje (1818-70), K. Janson (1841), Sivle (1857), and Garborg (1854), the Maltestaurer, have tried to create a literary language by collating and fusing together the various peasant dialects, the first named more especially in philological works, the others in poetry and novels. Garder in poems, Garborg is a writer of striking individuality. Asbjørnsen (1812-85) and Moe, the poet, and Faye collected the folk-tales; Landstad (1802-81), the hymn-writer, and Bugge (1833) collected the popular songs. Daa (1809-77) popularised the history of the country, and Vigerstedt (1812-73), the same direction in various works for the people. Schlütte (1823-73), Friis (1821), Ostgaard (1812-73), Magdalena Thoresen (1819), and others have described well and lovingly their native land and its people. Björnson (1832), M. Thoresen, and Lie (1846) have described the good life of the people; the peasant tales of Björnson are of great merit. Eilert Sundt (1817-75) strove to educate the country-people through his treatises on their social and economic circumstances. The chief writers of the latest phase of Norwegian literature are Ibsen (1828), Björnson, Lie, Kjelland (1849), Garborg, Camilla Collett (1813), Elster (1841-81), M. Thoresen, Jæger (1854), Flood (1837), Groescher (1838), Anner Skram (1847), Kristoffersen (1851), Krogh, Gunnar Heiberg, Hansum, and others. Speaking generally, these and all novelists, but Ibsen and Heiberg, show a strenuous desire for truth, great earnestness, a strongly realistic way of looking at things, keen delight in intellectual and moral strife, remarkable directness, vigour, and freshness of style, a decided leaning to satire, and frequently, too, a charming air of wit and singing originality. The socio-satirical plays of Ibsen (q.v.) have attracted notice in all countries, made him a conspicuous personality, roused not a little keen controversy, and affected the history of dramatic literature. Björnson (q.v.), best known abroad by his tales, has, like Kjelland and Lie, also done dramatic work, and produced some admirable poetry. Kjelland satirises the classes of whom Wellhaven was the representative; he has strong cosmopolitan, especially French, tendencies. Popular writers are Faroni and Mykle, who (1824-84) must be mentioned as voluminous and popular authors of works of a light character.

In other departments than pure literature the subjoined must be named: in literary history, Botkea-Hansen (1824-69), N. Lassen (1824), Johansen (1828), D. Boye (1828), in literary history, P. A. Munch (1810-63), Kaysen (1803-64), Lange (1810-61), Dane (1834), E. Sars (1835), G. Storm (1845), I. Moe (1814-50), Faye (1802-69), Nielsen (1843) in philosophy, Treschow (1731-1833), Monrad (1818), a Hegelian; in theology, Caspari (1814), Hange (1797-1866), W. F. Bugge (1838); in philology, P. A. Munch, Keyser, Bugge, Asen, Unger (1817), Fritzner (1812), Stockfleth (1757-1866); and, as orientalists, Caspari and C. Lassen (1800-70); in archaeology, Rygh (1833); in jurisprudence, Schweczgaard (1808-79), Lassen (1798-1873), Hauge (1807-82), Aschehoug (1808-82), and Sars (1835); in numismatics, Hanssen (1784-1873) and Abel (1802-29); in science, Michael Sars (1805-69) and his son, G. O. Sars (1837), as biologists, and Keilhan (1797-1858) and Th. Kjerulf (1825-88) as geologists. The best Norwegian painters have been Andreas Tidemand (1814-68), Gude (1825), M. Møller (1828), S. Jacobsen (1834), Munthe (1841), and Sinding (1842); the best sculptor, Middelthun (1820-86); the best musicians, Ole Bull (1810-80), H. Kjerulf (1815-63), Grieg (1843), and Svendsen (1840).

See Schweitzer, Geschichte der skandinavischen Literatur (3 vols. 1850-60); Grosse, Northern Studies (2d ed. 1882); Halvorsen, Norsk Forfatter-Lexikon, 1814-90 (1891 et seq.); Jæger, Norske Forfattere (1883); and Wegweiser zu einer exzellenten Bibliographie, La norvégie Littérature, 1824-60 (1869).

Norway Haddock. See BERGILT.

Norwich, a cathedral city of England, the capital of Norfolk, and a parliamentary, county, and municipal borough (the first returning two members), is situated on the Wensum, immediately above its confluence with the Yare, 18 miles north of the capital, and 114 miles by rail from London. (See Map, vol. i.)

Built on the summit and slopes of a hill which gradually rises from the river, the city, with its hamlets, covers an area of 7472 acres, as compared with that of two miles enclosed by its ancient walls (1294-1342), and its narrow, winding streets are rich in examples of early architecture—an Pull’s Ferry and the Bishop’s Bridge (1295), both on the river-banks; St. Giles’ Hospital (founded 1240); the Ethelbert Gateway (circa 1275); Bishop Salmon’s Gateway (circa 1229); the Guildhall (completed 1413); Eppingham Gate (1420); the Music House (formerly part of Norman, and once a residence of Sir Edward Coke); the Bridewell (Decorated and Perpendicular, circa 1400); and the Dolphin Inn (1547). The cathedral, almost wholly Norman in style, built in the first half of the 12th century, occupies a site close to the river, and was founded in 1096 by Bishop Herbert Losinga; its dimensions are 407 feet in length by 72 in breadth (or 175 across the transepts), and it is surmounted by a noble (Norman) tower and (Decorated) spire of 315 feet—the highest in England next to St. Paul’s. In addition to the nave and transept, rich in medieval sculptured bosses. Close by is the grammar-school, founded (as a Mortuary Chapel) in 1319, and famous as the place of education of Lord Nelson, Rajah Brooke, and other celebrities; also St. Andrew’s Hall (Perpendicular; formerly the church of the Black Friars), in which are held the triennial musical festivals, first established at Norwich in 1824. Next after the cathedral the most striking edifice is the castle, crowning the summit of a singularly mound in the centre of the city, and originally the seat of the Saxon kings; and the picturesque market-place; its massive quadrangular Norman keep, the only portion now standing, was used as a prison till 1866. In it and the adjacent prison-buildings has been placed the local museum, famous for its collection of raptorial birds. On the east-market beneath the castle is held annually, on Monday Thursday, the famous cattle and sheep
fair, formerly held on Tombland, and so graphically described in Bowyer's *Lavenbro*. The churches, forty-four in number, are for the most part built of flint, and in the Perpendicular style: those of St Peter Manerof (where once Archbishop Tenison ministered), St Andrew, St Giles, St Lawrence, St Michael Coslany, and St Stephen are the finest examples; whilst of public buildings of modern date mention should be made of the hospital (founded 1771 and rebuilt 1879-83), an Agricultural Hall (1882), and a Volunteer Drill-hall (1886). Formerly one of the largest seats in England of the worsted-weaving trade, the city is still noted for its textile fabrics—especially its crapes; but the principal manufactures now carried on are those of mustard, starch, ornamental ironware, boots and shoes, whilst extensive breweries and a vinegar distillery, as well as large nursery-gardens on the outskirts of the town, give employment to many hands.

Oft-times pillaged by the Danes, and in 878 Guthrum's headquarters, Norwich in 1064 was burned by Sweyn, and thirteen years later was held by his son Cnut. Subsequent to the Norman Conquest the principal incidents in its history have been the translation of the bishopric hitherto from Thetford (1094); the granting of a charter of self-government (1194); its burning by Louis the French Danph (1210); the riotous attack by the citizens on the cathedral monastery (1272); its first representation in parliament (1265); settlements of Flemish weavers (1336) and of Dutch and Wallois (1368-1369); a hurricane (1th January 1362), which blew down the spire of the cathedral; John Litester's rebellion (1381); disastrous fires (1463 and 1509), on the last occasion the roof of the cathedral being destroyed; the encampment of Ket's rebels on Moushole Heath (1540); many royal visits, and outbreaks of the plague, the worst being the Black Death in 1349, when half the population is supposed to have perished, in 1302, when 3076 persons died, and in 1305, when 2251 succumbed; and a collision on the railway 2 miles to the east of the city (10th September 1874), when twenty-five persons lost their lives.

Among the sixty-five bishops of Norwich have been Ralph (the pope's legate), Swithin (the builder of the grammar-school), Battenan (the founder of Trinity Hall at Cambridge), Despenser (*the fighting Bishop of Norwich*), Corbet (the poet), Harsnet, Smith, and others. The cathedral (afterwards of York and Canterbury), Wren (father of the celebrated architect), Joseph Hall, and Reynolds (the composer of the General Thanksgiving in the Prayer-book). Of citizens the best known are Sir Thomas Erpingham (builder of the gate which bears his name, and chamberlain to Henry IV.); Thomas Bilney; Archbishop Parker; Dr Clais; Greene (the poet and dramatist); Bishops Cosin and Tanner; Sir Thomas Browne; Dr Samuel Clarke; Sir James Edward Smith; 'Old' Crome, his son, and his grandson, Coffee (among the 'Norwich school' of painters); Mrs Opie; Grote (the musical composer); Wilkins (architect and R.A.); William Taylor (q.v.) and Professor Brewer; Sir W. J. Hooker; Gurney (the philanthropist) and his sister, Elizabeth Fry; Linley (the botanist); and Harriet Martineau, and her husband, Henry Martineau.

See works by Stacy (1810), Bayne (1858), Goulburn (1876), Jarrold (1885), and Jessopp (1884); also those cited under Norfolk.

Norwich, semi-capital of New London county, Conn., is at the head of the Thames River, 13 miles south by west of London. The chief portion of the city lies on an eminence that rises between the Yantic and Shetucket rivers, which here unite to form the Thames. There are numerous manufactories of paper, cotton and woollen goods, worsted, picture cords, pistols, wood-type, files, locks, iron pipes, &c., besides rolling-mills and ironworks; abundant water-power is supplied by the branches of the Thames. Steamboats ply between Norwich and New York. The land on which the city stands was granted by Uncus the Mohican to an English ensign who in 1636 reached him by night with a canoe-load of provisions, when he was besieged in his stronghold by the hostile Indians, and nearly forced by hunger to surrender: a granite obelisk bearing the name of Uncus was erected in 1825. Pop. (1880) 17,251.

Norwood, a south suburban district of London, hilly, healthy, and pretty, long the seat until 1797 of a Gypsy settlement. Pop. 24,797. See A. M. Gaper's *Norwood and Dulwich* (1891).

Nose, the organ of smell, and also part of the apparatus of respiration and voice. Considered anatomically, it may be divided into an external part—the projecting portion, to which the term *nose* is popularly restricted—and an internal part, consisting of two chief cavities, or *nasal fossae*, separated from each other by a vertical septum, and subdivided by spongy or turbinated bones projecting from the outer wall into three passages or *nasal passages*; the *ethmoid*, *sphenoid*, frontal, and superior maxillary bones communicate by narrow apertures.

---

**Fig. 1.—Longitudinal Section of the Nasal Passages of the Left Side, the Central Septum being removed:**

1. frontal bone; 2. nasal bone; 3. part of ethmoid bone; 4. sphenoidal sinus; a, superior turbinate bone; b, superior meatus; c, middle turbinate bone; dd, middle meatus; e, inferior turbinate bone; f, inferior meatus; pp, a probe passed into the nasal duct.

The external portion of this organ may be described as a triangular pyramid which projects from the centre of the face, immediately above the upper lip. Its summit or root is connected with the fore-head by means of a narrow bridge, formed on either side by the nasal bone and the nasal process of the superior maxillary bone. Its lower part presents two horizontal elliptical openings, the nostrils, which overhang the mouth, and are separated from one another by a vertical septum. The margins of the nostrils are usually provided with a number of stiff hairs (*vibrissae*), which project across the openings, and serve to arrest the passage of foreign substances, such as dust, small insects, &c., which might otherwise be drawn up with the current of air intended for respiration. The skeleton or framework of the nose is partly composed of the bones forming the top and sides of the bridge and partly of cartilages, there being on either side an upper lateral and a lower lateral cartilage, to the latter of which are attached three or four small cartilaginous plates, termed sesamoid cartilages; there is also the cartilage of the septum which separates the nostrils, and in association posteriorly
with the perpendicular plate of the ethmoid, and with the vomer, forms a complete partition between the right and left nasal fossae. It is the lower lateral, termed by some writers the alar cartilage, which by its flexibility and curved shape forms the dilatable chamber just within the nostril. The nasal cartilages are capable of being slightly moved, and the nostrils of being dilated or contracted by various small muscles.

The nasal fossae, which constitute the internal part of the nose, are lofty and of considerable depth. They open in front by the nostrils, and behind they terminate by a vertical slit on either side in the upper part of the pharynx, above the soft palate, and near the orifices of the Eustachian tubes, leading to the tympanic cavity of the ear.

The mucous membrane lining the nose and its cavities is called *pitsitary* (Lat. *pituita*, 'rheum'), from the nature of its secretion; or *Schneiderian*, from Schneider, the first anatomist who showed that the secretion proceeded from the mucous membrane, and not, as was previously imagined, from the brain; it is continuous with the skin of the face at the nostrils, with the mucous covering of the eye through the lacrymal duct (see Eye), and with that of the pharynx and middle ear posteriorly. This membrane varies in its structure in different parts of the organ. On the septum and spongy bones bounding the direct passage from the nostrils to the throat the lining membrane contains ample and capacious submucous pleureuses of both arteries and veins, of which the latter are by far the more large and tortuous. These pleureuses, lying as they do in a region exposed more than any other to external cooling influences, appear to be designed to promote the warmth of the part, and to elevate the temperature of the air on its passage to the lungs. They also serve to explain the tendency to hemorrhage from the nose in cases of general or local plethora. In this, the respiratory part of the nose, the mucous membrane is lined by ciliated epithelium. In the upper third of the nose—which, as the proper seat of the sense of smell, may be termed the *olfactory region*—the mucous membrane is very thick and coloured by a brown pigment. The olfactory nerve, or nerve of smell, terminates in the olfactory mucous membrane. It passes into the nasal cavity in several small branches; these ramify in the soft mucous membrane (fig. 2), and end in tiny varicose fibres which terminate in elongated epidermal cells projecting into the free surface of the nose. These cells—the olfactory cells—which are provided with little hairs, are affected by odorous particles, and the excitement thus set up travels to the brain by the branches of the olfactory nerve. In order to smell a substance it must be in the form of vapour. A scent such as Eau de Cologne enters the nostril by small particles, its little particles must be disengaged, and be carried freely by the atmosphere into the nasal cavity before we are affected by its odour. So sensitive is the nose, however, that odorous particles of immense smallness are capable of producing powerful sensations. When we remember that a grain of musk will scent the air in its neighbourhood for years, and that this can only be by the continual loss of particles of its substance, these particles must be infinitely minute. Still more wonderful is the development of the sense of smell in the living herbaceous plant. A smell will rapidly travel over the ground and the scent will under favourable circumstances remain for hours, and be sufficiently strong to enable the well-trained harrier to follow it with unerring accuracy. In savage tribes the sense of smell is vastly more acute than among civilised nations; nevertheless by practice it is possible for any one to cultivate this sense to a very considerable extent. Well-authenticated cases are recorded of persons obliged by the loss of the other senses to train this, the only one left for their use, to such a degree of acuteness that they have even been able to distinguish which of two objects or persons by the sense of smell alone.

Most persons imagine that we are largely beholden to 'taste' for our gustatory pleasures. In reality our sense of taste only enables us to distinguish sweet from sour or bitter, and all the flavour of the food or wine is smell. Close the nose and shut the eyes, and one cannot distinguish port from sherry, a raw potato from an apple, or beef from mutton.

Until recent years it was impossible to connect the quality of a smell with the kind of substance that produced it. In hearing and sight the character of the vibrations—of air or ether—determines the kind of sensation. The sound peculiar to the violin or piano depends entirely on the character of the sound vibrations given out by them. The rose appears red because it reflects to the vibrations which are chiefly characterised by their big oscillations. The writer of this article has been able to establish a similar relationship between the character of a smell and the character of the vibrations associated with odorous particles. He finds in study the colours of elements and their compounds, that in the 'Groups' of Mendeleeff (see Atomic Theory, Vol. I. p. 532) the colours are similar or vary with the atomic weight of the element. Exactly similar properties in respect to the production of colour sensations have been observed in olfaction.

**Diseases of the Nostrils.**—Acute inflammation of the nasal mucous membrane has been already described under the title of Catarrh (q.v.); the conditions which cause an offensive smell from the nostrils are discussed in the article OZENA; and Polyposis is a separate article.

**Hemorrhage from the Nostrils, or Epistaxis.** (Gr., 'a dropping'), is by far the commonest form of bleeding from a mucous membrane. It may be produced by direct injury, as by a blow on the nose, or a scratch in the interior of the nostrils; and by other local conditions, as ulcerations or
morbid growths in the nasal cavity. According to Sir Morell Mackenzie, 'constitutional causes are of four kinds: (1) the blood itself may be diseased; (2) the vessels may be diseased; (3) there may be obstruction to the blood supply of the liver, kidneys, or other organs, causing a sudden tension or strain of the whole system, which gives way at a weak part—viz., the nose . . .; (4) the blood-flow may be a vicarious discharge' (Diseases of the Throat and Nose). It is most common in children and young adults, least so in the prime of life. It is much more often met with in the male sex than the female. The bleeding usually occurs drop by drop, but may be very profuse. Sir Thomas Watson wisely says: 'Sometimes it is a remedy; sometimes a warning; sometimes in itself a disease.' The first question to be considered therefore in any particular case is whether the hemorrhage ought to be arrested. Generally speaking, in plethoric children and young people, in cases of venous obstruction, and in vicarious hemorrhage, it should not be stopped unless the loss of blood proves excessive or acute.

When it is desirable to arrest the hemorrhage the patient should be placed in the sitting posture at an open window, with the head erect or slightly inclined backwards; and amongst the simpler means that have tried are compression of the nostrils by the fingers, maintained for five or ten minutes, the application of a key or other piece of cold metal to the back of the neck, and the bathing of the face or whole head with cold water, especially if accompanied by a drawing-up of the water into the nostrils; should these means fail, recourse must be had to astringent injections (for example twenty grains of alum dissolved in an ounce of water) thrown up the nostrils by a syringe, or to astringent powders (as finely-powdered galls, kino, matico, alum, &c.) blown up the nostrils by means of a pill or other tube, or swilled up by the patient. As a final resource the nostrils must be plugged with strips of lint, absorbent wool, or a piece of sponge. Cases occasionally occur in which it is necessary also to plug the posterior orifices of the nostrils by an operation, into the details of which we have not space to enter.

Post-nasal Catarrh is a chronic and very troublesome disease, most common in America, especially the United States; so much so that it is there usually called simply catarrh, and elsewhere is sometimes spoken of as American catarrh. The symptoms are discomfort at the back of the nose, leading to frequent 'hawking' to clear away the tenacious mucus which is formed there, and sometimes indistinctness in articulation. The causes are not well understood; Sir Morell Mackenzie believes that the chief is the inhalation of irritating dust. Treatment must be chiefly directed to the local condition; alkaline sprays or washes should be used to remove the adherent secretion, and then an astringent powder or a thin ointment smoothed up the nostrils; catechu, red (Eucalyptus) gum, or hina, diluted with a little water and applied as a paste, either alone or with one-eighth of finely-powdered boracic acid, are among the most useful applications. Health otherwise defensive may indicate the importance of constitutional treatment; and change of climate is sometimes useful.

Nostradamus, the assumed name of Michel de Notredame, an astrologer of Jewish descent, who was born at St Remi in Provence, 14 December 1503. He studied at Avignon, and next medicine at Montpellier, took the degree of doctor of medicine in 1529, and practised the profession at Agen, afterwards at Salon near Aix. Next year when the plague was raging at Lyons he was conspicuous for his skill and devotion. He first fell upon his prophetic vein about the year 1547, but in what light he himself regarded his predictions it is not impossible to say. The first collection of famous Centuries appeared at Lyons in 1555. These were predictions in rhymed quatrains, divided into centuries, of which there were seven; the second edition, published in 1558, contained ten. Astrology was then the fashion, and these predictions were expressed generally in obscure and enigmatical terms, brought their author a great reputation. Catharine de' Medici invited him to visit her at Blois; the Duke and Duchess of Savoy went to Salon expressly to see him; Charles IX. on his accession appointed him his physician-in-ordinary. Nostra- damus died at Salon, 21 July 1566. His predictions have given rise to a vast illustrative or controversionary literature. The Centuries were formally condemned by the papal court in 1781.

See Jaubert's Vie de M. Nostradamus, Apologie et Histoire (N. coulon, 1783); Haitzen Meunier's Nostradamus (Aix, 1712); Astruc's Memoires pour servir a l'Histoire de la Faculte de Montpellier (Paris, 1707); Apologie pour les Grands Hommes Souvente de Magie (Paris, 1859); Plancher's Nostradamus (Paris, 1859).

Noteables, the name formerly given in France to persons of distinction and political importance. As the States-general were inconvenient to the despotism of the monarchy, the kings of the House of Valois adopted the expedient of calling in their stead Assemblies of the Notables, the Guide to which is given in the following page, and the condition of them being entirely dependent on the pleasure of the crown. For more than a century and a half even this poor acknowledgment of any other mind or will in the nation.
NOTTINGHAMSHIRE

than that of the sovereign ceased to be made; but when the state of the finances brought the monarchy into difficulties and perils Louis XVI, at the instigation of the minister Calonne, had recourse again to an Assembly of Notables, which met 22d February 1777, and was dissolved 24th May. He presided over 137 members, among whom were seven princes of the blood, nine dukes and peers, eight marshals, eleven archbishops, twenty-two nobles, eight councillors of state, four masters of requests, thirty-seven judges, twelve deputies of the Pays d'États, the civil lieutenant, and county councils. Every county was made to contribute in different cities. See Louis XVI, NECKER, FRANCE.

Notary-public is an officer of the law or professional person whose chief function is to act as a witness of any solemn or formal act, and to give a certificate of the same; which certificate, if duly authenticated, is accepted as good evidence of the facts done in the course of the act, and attested by him. Solicitors are sometimes notaries-public, but in England there are fewer notaries, comparatively, than in Scotland, where notarial acts and certificates are more largely used. The English courts take notice of the seal of a notary, but his certificate is not generally received as proof of the facts certified. A notary is employed in the noting and protest of foreign bills of exchange in case of non-acceptance or non-payment. In the United States the powers of notaries are defined by the laws of the different states. See Brooke, On the Office of a Notary (ed. by Leone Levi, 1876); and Proffitt, Law of Notaries-public in the United States (1877).

Notation. For Chemical Notation, see CHEMISTRY; for Musical Notation, MUSIC, Solfeggio; for Mathematical Notation, NUMERALS, ALGEBRA, CALCULUS, GEOMETRY, QUADRATURES.

Noto, an ancient episcopal town of Sicily, 16 miles SW. of Syracuse by rail. Pop. 15,925.

Notochord. See EMBRYOLOGY, AMPHIPODIUS.

Notornis, one among many of the family of Rails, with which reduced as to be incapable of flight, and which have within historical times become partially or completely extinct. Notornis inhabited New Zealand, and within the 19th century three specimens have been taken, one of them in 1881, so that possibility there are still a few survivors in some of the remote districts.

Nototherium, a genus of gigantic fossil kangaroo-like marsupials, found in Australia.

Not Proven. See CRIMINAL LAW.

Notre Dame (Old Fr., 'Our Lady'), the name of many churches dedicated to the Virgin Mary in France, particularly the cathedral of Paris.

Nottingham, a town of England, the capital of Nottinghamshire, and a parliamentary, municipal, and county borough (the first returning three members), is seated at the head of the Trent, 126 miles NW. of London, 140 miles NE. of London, and 16 miles S. by E. of Sheffield. Formerly surrounded by ancient walls (910-1265), of which all traces now have disappeared, the town covers an area of about 16 sq. m., and its appearance of late years has been much improved by the widening of its streets; by the erection of a new town-hall, University College, and other public buildings; by the opening and laying out of an arboretum, of 17 acres, of a public park and recreation grounds of over 120 acres, and of a tract of open land, called 'Butterwell Forest' (135 acres); as also the forming of the Trent Navigation, which is here about 200 yards wide, with a broad granite and iron bridge in the place of a former narrow structure of seventeen arches. Crowning a precipitous rock, which rises 133 feet above the river, stands the castle, built (1674-83) on the site of an ancient Norman fortress, dismantled during the Parliametary wars, and itself much damaged by fire during the Reform Bill riots of 1831. It was restored in 1878, and transformed into an art museum. Near to it are the county hall (1770); St Mary's Church (restored 1867-85), a cruciform building in Perpendicular style; the University College (1757-81), a spacious market-place, 54 acres in extent, having at its eastern end the exchange, with a richly-decorated façade (rebuilt 1814). In another group not far off are the guildhall and other municipal offices (1883), in the French Renaissance style of architect; two houses of the County College (1757-81), mainly a science school, but accommodating in its wings a free library and natural history museum. Other edifices worthy of mention comprise a hospital (1781, with additions 1829-79); a Roman Catholic cathedral (1844), enornous and Early English; and the high school, founded as a grammar or free school in 1543, moved into new buildings in 1867, and since 1882 controlled under a new scheme; it has a large income from endowment, and annually offers for competition eight exhibitions of an aggregate value of £53, besides numerous scholarships. On the outskirts of the town meetings were held annually in March and October for a hundred years until 1890; the Trent Bridge cricket-ground is the scene of the county's home matches; whilst mention must not be omitted of the annual goose fair held at Michelmores. Of the various industrial fabrics carried on in the town, the most important are those of lace and hosiery; baskets, bicycles, cigars, and needles are also made, whilst several iron-foundries are in operation, and malting and brewing are extensively carried on. One of the most successful sewage farms in the country has been laid out 5 miles from the town, the whole of whose sewage is here dealt with. Pop. (1801) 28,801; (1811) 50,220; (1821) 18,575; (1891) 213,984. In the history of Nottingham (which was one of the Five Boroughs) the principal incidents have been its occupation by the Danes, and their withdrawal on the conclusion of a treaty for peace (968); its destruction by fire (1140 and 1153); the granting of its first charter (1185); the convening here of three parliaments (1320-75); the appointment of its first suffragan bishop (1394); the raising by Charles I. of his standard on the walls; the commencement of the military war (1642); and riots (1793-1816), partly on account of a bread famine and partly owing to the Luddites (q.v.). See local works by Dickinson (1816), Wylie (1833-63), Hine (1876), and W. H. Stevenson (4 vols. 1890), besides those cited under the county.

Nottinghamshire, or NOTTS, an inland county of England, bounded on the N. by Yorkshire, E. by Lincolnshire, S. by Leicestershire, and W. by Derbyshire. Its greatest length is 50 miles; average breadth, 20 miles; and area, 284 sq. m., or 557,352 acres. Pop. (1801) 140,557; (1811) 216,815; (1821) 443,823. Apart from the valley of the Trent, which is very flat, the general aspect of the county is undulating and well wooded, the highest ground—600 feet above the sea-level—being in the west, in the vicinity of Sherwood Forest (q.v.). In the south are the Wolds, consisting of upland heath, moors and pasture-lands broken up by many fertile hollows, whilst the northern boundary for upwards of 15 miles is skirted by the Car, a tract of low-lying land, formerly a swampy bog, but since 1796 drained and brought into cultivation. The Trent, which rises in the Wolds, and is formed by the joining of the Trent and Welland, which is the principal river: and the Fosse Dyke and Notts and Grantham canals, and Midland, Great Northern, and Manchester, Sheffield and Lincoln railroads also traverse the county. The climate, especially in the east, is remarkably dry, and the soil varies, sand and gravel, clay, limestone, and coal-land prevailing.
in different districts. As regards productivity it is not above mediocrity, except in the Vale of Belvoir to the east of Nottingham. Of the total area under cultivation, corn and green crops cover about one-fifth; wheat, barley, sand-hill and spring wheat, 200,000 acres; whilst some 3000 acres are orchards and market-gardens. The cultivation of hops has been discontinued. The principal mineral products are coal—of which about 7,000,000 tons are raised annually—gypsum, iron ore, and limestone. The manufactures of the city are cloth, glass, Nottingham, Newark, Mansfield, Retford, and Worksop, the two former also being the scene of most of the historical events connected with the county. Lying wholly in the diocese of Southwell, Notts is divided into six wapentakes, nine poor-law unions, and 273 parishes, and returns seven members to parliament, one for each of its four divisions (Bassetlaw, Newark, Mansfield, and Ruskington), and three for Nottingham (its capital and assize town). The county council consists of sixty-eight members. Of its natives the best known are Archbishops Cranmer, Seeker, Stern, and Manners-Sutton; Garnet (the Jesuit); Denzil Lord Holles; General Sir William de la Warr, and his contemporary Colonel Hutchison; Lady Mary Wortley Montagu; Bishop Warburton; Dodsley, Kippis, and Wakefield (the authors); Alcock, and several Sandyhills, with a beautiful poet named Wordsworth; Dr Erasmus Darwin; Edmund Cartwright; Fynes Clinton (the scholar); Kirke White and Bailey (the poets); Lord Byron; ‘Speaker’ Denison; and ‘General’ Booth. See the county histories by Thoroton (3 vols. 1797), Bailey (4 vols. 1832-55), Burton (1851), and Winter (1856).

Nojum, capital of the French penal colony of New Caledonia (q.v.). Pop. 5000.

Noun. See GRAMMAR.

Noureddin. See NUR ED-DIN.

Novalis, the pen-name of Friedrich von Hardenberg, German writer, who was born at Wiederitz, near Mansfeld, in Prussian Saxony, 21 May 1772. Whilst being educated at Jena, Leipzig, and Wittenberg he came under the influence of Schelling and Fichte, and he soon became a useful companion of Fichte, Fr. Schlegel, and Tieck, studied domestic politics of Rochen, and imbued himself with the spirit of Romanticism to such an extent that he was afterwards designated the ‘Prophet of Romanticism.’ He made his start in life as a mining official. At Wittenberg he fell in love with a young girl, whose early death left a lasting impression upon him. Ere many years were past he himself, deliberate from his boyhood up, was seized with consumption, and died 26th March 1801. The principal tenets of his two philosophical romances, both left incomplete, ‘Heinrich von Ofterdingen’ and ‘Lehrlinge zu Sees,’ were that life ought to be poetry realised in practical conduct, and that there are in the universe many verities and realities the truth of which cannot be grasped by the cold, critical intellect; they can only be known by the sympathetic intuition of feeling. His Hymnen an die Nacht are a glorification of his sorrow at the loss of his mistress. These, together with his Poems and Sacred Songs, are the only finished productions he has left. Novalis penned numerous reviews and suggestive sentences, often in very graceful language, but on the whole his writings lack precision of thought and robust common sense; their prevailing atmosphere is a mystical twilight, where is much obscurity, but also much beauty and much deep feeling. His Schillerische Werke (2 ship. vols.) were published by Tieck and Fr. Schlegel in 1862. To these a third volume, containing a supplement to the Life printed in vol. i., together with poems and philosophic fragments by Novalis, was added in 1846. See Carlyle’s Miscellaneous Essays (vol. ii.), the German Life of Novalis published at Gotha (2d ed. 1883), and his correspondence with the Schlegels (Mainz, 1880).

Novara, capital of a North Italian province, 60 miles N. of Turin by rail, with several fine churches, a statue in silic, grain, and wine, and manufactures of silk, cotton, and linen. Here the Austrians were utterly defeated by the Austrians under Radetzky, on 23d March 1849. Pop. 19,557.

Nova Scotia, a province of the Dominion of Canada, lying between 43°25′ and 47°N. lat., and 59°40′ and 60°23′ W. long., consists of a long, narrow peninsula, and the island of Cape Breton, which is separated from the mainland by the Strait of Canso. It is bounded on the N. by Northumberland Strait (which separates it from Prince Edward Island) and by the Gulf of St Lawrence; NE., S., and SW. by the Atlantic Ocean; W. by the Bay of Fundy; and NW. by the Bay of Alnmusk. The whole coast is remarkable for the beautiful scenery of its Atlantic and Gulf shores, and the scenery of the interior, especially in the districts near the sources of the St Lawrence and the Bay of Fundy. There are fine sandy beaches, and the climate is warm and sunny, but the winter is very cold. The coast-line is about 1800 miles in length, and the shores abound with excellent harbours, of which the chief are Halifax Harbour, Chedabucto, St Margaret’s, Alma, and St Mary’s bays, Annapolis, Mines, and Chignecto Bay, and the banks of the Acadian Sea. There are numerous rivers, but few of them are more than 50 miles long. The most important are the Avon, Annapolis, and Shubenacadie. Of the rivers of Nova Scotia fifteen flow into the Northumberland Strait, four into St George’s Bay, and one-third into the Gulf of St Lawrence, twenty-four into the Bay of Fundy. Among the lakes the chief is Great Bras d’Or Lake (which is really an inland sea), about 50 miles long, and with an area of about 500 square miles, and a depth of water varying from 12 to 24 fathoms. The lakes and bays on the southern coast are lake Rossignol, 20 miles in length, Ship Harbour, 15 miles long; Grand Lake, and College Lake. The most remarkable body of water in the province is Mines Basin, the east arm of the Bay of Fundy, penetrating 60 miles inland, and terminating in Cobequid Bay. The tides rise in the basin with great impetuosity, and form what is called a ‘bore.’ At the equinoxes they have been known to rise from 40 to 50 feet. On an average, however, the rise is about 30 feet, while in Halifax Harbour, on the opposite side of the coast, the spring-tides range from 22 to 24 feet. The province is about 70,000 square miles in extent, and is one of the most beautiful and fertile regions of North America. The coast is beautifully variegated by ranges of hills and broad valleys, both of which run longitudinally through the province. The Cobequid range of mountains, as they are called, run through the interior of the province. On each side of these mountains are long tracts of rich farming lands. The Annapolis valley is especially favourably situated, and is noted for the magnificent apples grown there. The southern part of Cape Breton is very much the same in appearance as the northern part of the mainland, but the northern part of the island is bold and steep, the land at North Cape being 1800 feet above the sea-level. The distance from North Cape to Cape Ray on the Newfoundland coast is 48 miles.
The principal cities and towns are Halifax (40,000), Dartmouth (40,000), Yarmouth (6000), Truro (7000), Parr'sboro (2000), Windsor (8000), Kentville (4000), Annapolis (2000), and Digby (1500). The climate of Nova Scotia is remarkably temperate considering its northern latitude. The extreme of cold is 20° below zero, and the extreme of heat 89° in the shade. The climate is also less damp than that of any other part of the British provinces. The temperatures of the eight degrees warmer than the eastern, and in Annapolis county the mercury rarely falls below zero. Vegetation is very rapid, and the autumn forms a delightful season. Spring is rather tedious, and the weather is variable. Fogs are prevalent along the coast, but do not operate inland to any extent.

Agriculture and horticulture are among the principal industries in the province. Rye, oats, and barley, buckwheat, Indian corn, tomatoes, potatoes, turnips, and all root-crops grow in abundance. Wheat is not grown to any great extent, although there is nothing to prevent its cultivation. Apples, pears, plums, cherries, and other garden fruits attain the utmost perfection. The apple-orchards in Annapolis and King's counties are very productive. They extend along the roadside in an unbroken line, presenting a sight which, once seen, is not soon forgotten. More attention is now being devoted to dairying and to the raising of live stock than was formerly the case. The manufactures of the province are yet limited, but are being developed. Cottons and woollens are manufactured in various parts of the country. There are ironworks at Londonderry, steel-works at New Glasgow, and stove and hardware works at Amherst; and there are also several sugar-refineries, paper-mills, boot and shoe and other manufacturers of leather, manufacturers of sawmills and other machinery, furniture, and wooden ware, and many sawmills. The shipbuilding industry was formerly a most important one, but has suffered from the substitution of iron for wooden vessels. Endeavours are, however, being made to develop the iron shipbuilding trade.

There are 700 miles of railway in the province, and many new lines are projected. The province is connected by railway with the States railway-systems. There are two canals in the province, one from Halifax to Cobequid (not now in use), and the other connecting St Peter's Bay and Bras d'Ore Lake. The ChiUnego Ship-railway, already referred to, is meant to carry the hogs heads over the isthmus of Chignecto, so as to avoid the long detour necessary to pass from the Gulf of St Lawrence to the Bay of Fundy and the United States by way of the Nova Scotia coast.

The religious denominations according to the census in 1891 were as follows: Roman Catholics, 122,452; Presbyterians, 198,932; Baptists, 83,129; Church of England, 64,410; Methodist, 54,165. Education is free, and there are numerous public schools and academies, besides a normal and middle school, several convents, and the following six colleges: Dalhousie College and University, St Mary's College (Roman Catholic), and the Uren
terian College, Halifax; Acadia College (Baptist), Wolfville; St Francis College (Roman Catholic), Antigonish; and King's College and University, Windsor. The last, belonging to the Church of England, was opened in 1864.

The public affairs of the province are administered by a lieutenant-governor, and executive council of nine members, and a legislatiue assembly of thirty-eight members elected by the people for four years. The province is represented in the Dominion parliament by ten senators and twenty-one members of the Lower House. The tax revenue in 1893 was $892,462. The annual revenue of the province in 1893 was $769,676, of which $432,867 represented the contributions from the Dominion treasury, under the terms by which Nova Scotia became a member of the Confederation; the rest was made up of mining royalties, receipts from fisheries, &c.

The government, offer land on reasonable terms—100 acres for $40. The wild land is, however, covered with bush, and has to be cleared before cultivation is possible. Improved farms can be purchased in different parts of the province at prices ranging from $4 to $20 per acre, including buildings, &c. Excellent shooting and fishing are to be found all over the province, especially in the less accessible parts, where big game is still fairly abundant.

History.—Nova Scotia was first visited by Cabot in 1497, and the first colonisation is recorded that in 1604 of the French under De Monts, who attempted for some years to form settlements at Port Royal—now Annapolis—St Croix, &c. The settlers were finally expelled by the colonists of Virginia, who claimed the country by right of the discovery of Cabot. Other attempts were made at colonisation, but with small success. The country was ceded to France by the treaty of Breda in 1667; its possession, however, remained a source of contention between England and France, until it was finally ceded to England by the treaty of Utrecht in 1713. A memorable event in the history of the province was the expulsion of the Acadians (q.v.) in 1753; some of the events connected with which are the subject of Longfellow's Evacuation Day. A number of naval engagements were fought off the coast in the American War of the Revolution, and the struggles between the French and British, especially in the neighbourhood of Louisburg (q.v.). In 1713 it was annexed to Nova Scotia. It was subsequently made a separate province, but again united to Nova Scotia in 1819. Many attempts were made to develop the iron deposits discovered; however, the present position date from the immigration in 1784 of the loyalists who preferred to take up their homes in British territory rather than remain under the dominion of the United States. The province of
Novelists. See Justinian.

Novelle. See Justinius.

Novelties. Novellæ, or novelle, 'novels,' are the true novellas. Often the name is confined to the works of the early Italian and Spanish novelists; but the novel, as a name of a thing, came to us with the thing itself from Italy early in the reign of Elizabeth. Boccaccio, from whom Painter took the 'excellent novelty' in his Palace of Pleasure, deserves somewhat indifferently, and in his preface speaks of 'novels or fables or parables or stories' as if they meant pretty much the same thing: but in Provencal, and according to the Cento Novelle Antiche, 'novella' or 'novella' seems to have meant originally some new drollery, jest, or bon-mot—something, as Borghini explains, that pleased by its freshness, and the 'nouvelle' or 'novellatore' to have been a kind of jester who collected and retailed such things. Most of the Cento Novelle and a large number of Boccaccio's, notably those of the sixth, seventh, and eighth days, are as far as we know the collections of Sacchetti and Ser Giovanni the proportion is still greater. In fact the primitive novella was something much more akin to the fabulae of Poggio, the Cent Nouvelles nouvelles, the stories of the Héptameron, the Hundred Merry Tales, and even their humble relatives, the jests and tales of Joe Miller, than to the long, grave, and often tragic narratives that appeared under the title when it had grown elastic in the 16th century. But if 'novel' has departed from its original significance, 'romance' has wandered still further. The word originally meant something whatever to have with any form or species of composition. It was simply the name given in the middle ages to the spoken language of the commonalty, particularly in France and Spain, in contradistinction to the Latin or Latinized languages of the court or the learned classes, and the language used in documents and writings of all kinds. In time, however, it came to mean not only the vehicle but also the thing conveyed; anything in Romance was called romance, and naturally the term was extensively applied to the great sources of popular recreation, the songs of minstrels and troubadours, by which it was in the end almost monopolised. Hence the two meanings of 'romance' in Spanish—(1) the vernacular ("ten buen Romance" is the precise equivalent of our phrase 'in plain English'); (2) a piece of popular

The English word "novel" comes from the French "novelle," which in turn derives from the Latin "novella," meaning a new or recent thing. The word was first used in the 16th century to refer to short, narrative poems, and later to the tales written by Italian and Spanish authors. The early Italian and Spanish novelists contributed to the development of the novel as a literary form, which would later become a widespread and influential genre. The novelists and their works are often cited as foundational in the history of literature, providing models for later writers and influencing the development of modern storytelling.
narrative poetry such as we mean by the word 'ballad.' In France the place of the ballad was supplied by much longer and more elaborate compositions, like the *chansons de geste*, and to these the title of 'romans' was very generally given. But it must be admitted that the 'romance' or 'romans,' as it was applied, in Scarron especially, and in France nearly exclusively, but exclusively, to compositions in verse, and that the prose-works which we now call the romances *par excellence* were not so styled in their own time. The romances of chivalry were called by their authors and critics chroniques, histories, or books; but, except in one literary race, the English, did not become romances; and the still more typical romances, the heroic romances of the 17th century, *Poletandre*, *Cassandre*, *Pharamond*, *Thirubain*, and the like, seem to have been inherited from Scarron, but certainly not to their authors, for the name. Neither 'novel' nor 'romance,' in short, has any historical or etymological claim to stand for the latest development of prose fiction; nor is there any warrant for a distinction between the novel and the romance founded on a predominance of the verbal or of the dramatic or the extra-ordinary, the comic or the tragic. But this is the only instance in which, in practice, it would be impossible to draw. The names are purely conventional. What we call a novel the French call a roman; if they shared our somewhat contemptuous feeling for the romance there would be no modern novel. As our example, we may perhaps have followed them in this respect; if, instead of bad news, we talked of hearing bad novels.

For the origin of the thing so called there is no need to search very far. To ask where fiction came from is not much different from asking who invented the wheel. If we must find a source for it, or fix it upon someone, a child in a corner telling a story to itself, with its playthings, or Maggie Tuliver unfolding the tale of the earwig's domestic troubles to her cousin Lucy, will be as near the fountain-head of fiction as we need go. The demand for fiction seems to follow very closely upon the demand for food. 'Tell me a story' is among the earliest expressions of our wants in life, and so far as we can see it has been one that has been immemorial in the earth, and always story-tellers of one sort or another are to be found striving as best they can to comply with the call. It is true that we cannot see very far back, and that our only available sources of information convey a very imperfect idea of story-tellers and story-telling in the remote past. The fragments and specimens that have come to us through tradition and literature can no more give a complete view of the fiction of the age they belong to than the fossils in a cabinet of the fauna and flora of the globe when they were living things. They have been selected by chance, or by the possession of some property or feature conducing to preservation, while types and species less favored have left no trace behind them of their existence. To take an example, every one at all acquainted with the must have noticed how strongly the didactic element asserts itself in early eastern fiction. Of the far greater number of the specimens that have come down to us through the *Panachatantra*, *Histoires*, *Bidpai*, Lokman, *Asop,—for in strictness he must be counted among the Orientalists,—and other channels are fables with a moral attached. Now, it is a matter of history that Don Juan was well fitted to explain the eastern type of fiction. Children call for stories, but not in real life at least) for instruction or improvement until some years have passed over their heads; and what is true of children is true of humanity. But the very earliest productions of the fable family are entirely destitute of this appendage, and are mere stories told for their own sake. Properly they belong to a still earlier type than the fable, the story where animals and inanimate things speak and act like human beings, the immediate descendant, no doubt, of the story the child tells to itself about such objects as take its fancy. It is a very strange story how the moral came to be added, and how, once added, it became protective. The story furnished with a moral was preserved by and for the sake of its moral when those told for the story's sake alone dropped out of circulation; and in virtue of it found its way into literature as if there was a literature to receive it. It is simply an instance of survival of the fittest; not necessarily of the best, but of the best fitted to survive in the struggle for existence.

The case of *Asop* above referred to is an illustration of the connection between oriental and European fiction. Some critics maintain that he was an Oriental himself, and identify him with Lokman; but without going so far it may be safely said that the fables bearing his name are mainly of oriental origin, and from some source in common with the *Panachatantra*. It is probable that the Greek *prose* fable came from Asia Minor, or from islands off the coast, and in most instances the Asiatic influence is distinctly perceptible. Of the Miletian tales we know little, but from that little it seems clear that the *prose* fable took what in the nature of the French fabulians, and like them largely indebted to the eastern story-tellers. *Iamblichus*, the author of the *Babylonica*, and *Heliodorus*, the author of the more famous *Erythraea*, were people whose acquaintance we may well have presumed to be in like employment, and if we may credit the statement of *Chloe*, which is founded on the character of *Chloe*, that *Achilles Tatius, the follower of Heliodorus*, was of Alexandria. Xenophon, who wrote the tale of *Abrocomas and Anthia*, was of Ephesos. *Josephat* and *Barlom* was by John of Damascus. *Lucian* was another Syrian, but he cannot be properly included among those who wrote stories for the story's sake, nor indeed among those distinctly influenced by eastern fiction, any more than the author of the graceful pastoral of *Daphnis and Chloe*, whoever he may have been, for 'Longus' is a name which has been more or less the usual title of various writers. And *Callistrat* says, in his *Histoire du Roman*: 'The taste for the romance passed from the East to Greece; but it was to the artistic instinct of the Greeks that the novel or romance owed the remarkable development we see in *Daphnis and Chloe* and *Theognis and Charicles*. The taste passed into Italy about the same time, but more probably through the medium of the Miletian and *Sylarita* tales than directly from the East; and it bore fruit in the *Sulpican* of *Petronius Arbiter* and the *Metamorphosis*, or *Golden Ass*, of Apeleius, in each of which the best known episode is derived from an eastern story. The *Cupid and Psyche* of Apeleius and *Petronius*' *Widow of Ephesus* are found in divers forms, and of the latter there is even a Chinese variant.

The collection of fables, partly from the *Panachatantra* and *Histoires*, called *Kaliya vinoda* or *Kalideva* had a great share in the spread of oriental stories in the middle ages throughout western Europe, but elided in Spain, where, introduced probably by the Arabs, it helped to furnish material for the *Disciplina Clericalis* of Pedro Alfonso and the *Comite Lucernar* by Don Juan of *Oviedo*. It is a species of eastern story, and was a work that still circulates as a chap-book in most European countries, the *Seven Wise Masters of Rome*, which, under a variety of titles, *Erastus*, *Dolopathos*, *Syrphygus*, *Sindbad Nameh*, *Sandalor*, *The Seven Viziers*, and through Latin, Greek, Hebrew, Arabic, and Persian, may be traced back
Montemayor's Sannazaro, lay a fables long verse. It was large indebted to this source, but not nearly so much as the fabliaux (properly 'fableaux,' diminutive of 'fables') of the trouvères, who found in the inventions of the early story-tellers precisely the sort of tale which their easy verse and spirit gondois could readily adapt to the taste of their audiences. It was from the fabliaux that the Italian novellieri, from Boceccio to Bandello, and not only they, but also the compilers of the Cent Nouvelles nouvelles and of the Heptameron, and the gay novel-writers of the 16th century in general, chiefly took their lightest, liveliest, most acquired, and sometimes most licentious tales; and in this way the fiction of the East came in numberless instances to be incorporated in the literature of Europe.

But the trouvères were at the same time laying the foundations of another very different species of verse: the poet of a feudal humanity, familiar by The Thousand and One Nights—were very numerous at the time, and served as a mine of oriental fiction to medieval Europe. The Gest of Raimon, which is in fact a European story-book, was largely indebted to this source, but not nearly so much as the fabliaux (properly 'fableaux,' diminutive of 'fables') of the trouvères, who found in the inventions of the early story-tellers precisely the sort of tale which their easy verse and spirit gondois could readily adapt to the taste of their audiences.

on chivalry, partly on pastoral romance; their strength lay in their combination of sentiment and swagger, the latter borrowed from the chivalry romances of the remote past; and hence one merit, perhaps, was that they provoked some excellent satires, such as Boileau’s ‘Héros de Romain,’ Furetière’s ‘Roman Bourgeoys,’ Sord’s ‘Berger Extraesquent,’ Scarron’s ‘Roman Comique,’ and Mrs Lennox’s ‘Female Quizote.’ But a far more important story of fiction came into existence in Spain in the time, and partly through the influence, of the chivalry romances. These were every day growing wilder and wilder and more and more regardless of all common sense and observation of decent probability, when a little book by a tavern keeper named Lázaro de Alarcón was published in 1560, at a time when the chivalry romances, complete with their prevarications, mere appearances. It did not pretend to be a satire or even a protest against the romances in fashion; it merely suggested that a story just as interesting and amusing might be got out of real, everyday life, without magicians, giants, flying dragons, or enchanted palaces, seeing that tastes varied, and that, as Jean Sangrain of Lyons put it in the French translation of 1600, it was not everybody that took delight in reading of heroic deeds. And in fact the Lázaro is studiously unheroic, and the exact opposite of a romance of chivalry. The hero, instead of being rich, hunger and thrashings are the dragons and giants he has to encounter; his adventures and achievements are cheating and outwitting his masters; the empire of Trebizond that crowns his career is the office of town-crier of Toledo, and the princess that bestows her hand upon him, the doubtful house-keeper of a sly old priest. It was the first genuine attempt at realism in literature, and for the first time in the history of fiction readers found themselves taking pleasure in the creations of the storyteller, not because they were remote from ordinary experience, but because they were familiar. Finding favour, as a matter of course it had successors. It was followed by the gusto picurésco novels, the tales of Spanish rogue and vagabond life, of which Guzmán de Alfarache, Marces de Obregon, and Quevedo’s ‘Vida del Duxon’ are the best-known examples, none of which, however, are particularly in deference to the precedent of Lázaro, partly because it was a life rich in adventures and incidents, but chiefly because it was a phase of life familiar and real to all readers in Spain in the 17th century. And not in Spain alone, apparently, for there is a marked resemblance in the English novels of this period which seems to have been recognised wherever there were readers in Europe; the best of them were translated almost immediately into French, and very soon into English, Italian, German, and Dutch, and, as repeated editions show, took their place everywhere among the acknowledged purveyors of amusement. In Germany, indeed, they may be said to have laid the foundation of the novel in Grimmeilenhausen’s ‘Simplicissimus,’ and in England we need only turn to Defoe for proof of their influence. Colonel Jack and ‘Moll Flanders’ are picurésque novels pure and simple, with their parentage stamped upon their features, and there are marks about Captain Singleton and Roxana that show them to be of the family.

But it was through Le Sage that the picaresque novel came to be influential in shaping modern fiction. Like many other writers of his time, Le Sage detects in some wild plant useful properties that may be indefinitely developed by cultivation, or germ that only need the gardener’s skill to expand into endless varieties of form and colour, Le Sage was able to cut through gross brutality of chivalry with humour, and how its asperities might be removed without impairing its virtues. It may be said it was a great discovery to perceive that disreputable life is not the only one that offers material available for a story of real life, that rascality and rogery are not the only qualities from which amusement and edification may be derived. It may be the artistic advantages of a censure, there is on the whole more to be made of a hero who will be accepted by the reader as a man and a brother. But this is only what is said of every discovery as soon as men have come to look upon its consequences, and matters of course. Great or small, however, this was Le Sage’s discovery, and whether it was of importance or not the modern novel of real life and character will show. It would be difficult, perhaps, to define with precision the extent of Le Sage’s share in the formation of the modern novel. We can give no answer to that question, but of its reality there can be no question. To take only one illustration out of many—in David Copperfield and elsewhere Dickens has left it on record that the favourite stories of his boyhood were ‘Roderick Random’ and ‘Peregrine Pickle,’ a training which shows its fruits in ‘Pickwick’ and all his early works; but if Gil Blas was in the same way Smollett’s primer in fiction we have his own word for it that it was the model he set before him when he undertook to ‘point out the follies of ordinary life. This much, at least, cannot be disputed, that it was very near a man’s nature to give a sort of art of storytelling, the first to show an artist’s knowledge of the value of details and the right use of realism, and the first to make clear the distinction between the novel and prose fiction in general. ‘Pantagruel and Goliath’s Travels’ are not novels, not because the ordinary characteristics of the novel are wanting, but because Rabelais and Swift have merely assumed the disguise of a storyteller for the sake of gaining access to quarters otherwise inaccessible, precisely as Burton put on a pilgrim’s dress in order to get into Mecca. In Don Quixote and Robinson Crusoe there may be just as little of the conventional features of the novel, but there is no disguise; they take their places among the novels unchallenged, while the title of Tristram Shandy must remain at least questionable, for though it may be called ‘The Life and Opinions of Tristram Shandy, Gentleman,’ it is ‘the freaks and grimes of the Rev. Laurence Sterne.’ Le Sage’s theory, so far as we may infer from his practice, seems to have been that to tell a story is the novelist’s business, and to keep to it with singleness of purpose his duty as an artist.

In the foregoing necessarily brief outline of the history of the novel it will be seen that in its growth there has been at work a process very much like that which regulates other growths. One form springs from another, supplants it through being better adapted to surrounding circumstances, and lasts just so long as the adaptation lasts. In the novel, too, as in other cases, forms that have been in this way pushed aside have a tendency to reappear if circumstances favour them. The long-winded sentimental novels of the 18th century were only a reversion of the romances de langue hotine of the 17th in a soil that happened to suit them; and in the novels of Horace Walpole, Clara Reeve, and Mrs Radcliffe the spirit of the later romances of chivalry asserted itself, just as the spirit of the older and truer chivalry romance found expression in Scott. ‘Waverley’ and ‘Rob Roy’ were romances of chivalry, modified only by genius and modern influences. In its extraordinary powers of multiplication and variation also the latter-day novel seems to be subject to natural law. The varieties of story that can be woven out of the stuff of life are strongly marked; but no sooner does man for his pleasure or comfort appropriate any living thing, dog or pig, rose or cabbage, than it acquires a
Novgorod (Lat. novem, 'nine') was among the Romans the ninth month of the year (the Ger. Wind month) at the time when the year consisted of ten months, and then continued 30 days. It subsequently was made to contain only 29, but Julius Caesar gave it 31; and in the reign of Augustus the number was restored to 30, which number it has retained to this day.

All Saints (1), St Hubert (3), St Martin (11), St Catharine (25), and St Andrew (30).

Novgorod ('new-town'), a famous city of Russia, capital of a government, is situated on the Volkhof, near where it issues from Lake Ilmen, 110 miles SSE. of St Petersburg by rail. It is the cradle of Russian history. In 364, according to tradition, Ruirk (a Varangian, apparently Scandinavian) was invited hither by the neighbouring tribes, and from him begins the history of the country and the line of its sovereigns. As early as the 12th century it had important connection with the Hanseatic League, and was the first naval power of north-east Europe. During the time of its prosperity the town was called Novgorod the Great, and had 400,000 inhabitants, and extended its sway to the White Sea and the river Petchora. Its government was a sort of republic. The greatness of Novgorod was proverbial among the princes of Moscow, and in 1471 the czar Ivan III. nearly destroyed the town, bereft it of its liberties, and exiled the most influential citizens; and when Archangel was opened for English trading-vessels, but especially after the Foundation of St Petersburg, its trade fell away, and the town rapidly declined, till now it is but the shadow of its former self. Of the existing ancient buildings the most remarkable are the church of St Sophia, founded

Variability and fertility apparently limitless. Thus it has fared with the novel ever since Le Sage undertook the domestication of an adaptable species. Having become not merely a source of amusement, but of connoisseurship, and several aspects of its life, it now rivals the rabbit in fecundity, and runs into varieties more widely different than greyhound, bulldog, and toy-terrier. This luxuriance of growth, however, cannot be regarded with unmixed satisfaction. It would be no small evil if the novel from its luxuriant branch of literature were to degenerate into a manufacture, and yet a certain tendency that way cannot be denied. Another, due to the same cause, is the tendency of the modern novel to usurp functions that do not appertain to it. In some cases it is by no means evident that the pretence of lofty motives is sufficiently transparent. It is no more true that excursions into the slums of realism and naturalism have for their object the scientific study of social evils than that exhibitions of fasting men are got up in the interests of science. But the novel that is a preaching, a treatise, a dissertation in disguise, though less disingenuous and disagreeable, is no less an abuse. The prodigious development of novel literature in recent times seems to have led to overweening pretensions. We are sometimes told that the novel has become the dominant art of the age, the teacher who holds the keys of philosophy, science, all human knowledge. But fine words will not alter facts. The raison d'être of the novelist is the old craving for a story, and those of the craft who have most frankly recognised this have always been those whose books were of their own generation and most honoured by posterity. Scott, the master of them all, claimed to be no more than a story-teller, and was proud of the title.

The best histories of the novel are Dunlop's History of Prose Fiction (1914; 3d ed. 1945), German texts, with large additions by F. Liebich, 1931; a complete new edition by E. Wilson (1888); O. L. B. Wolf's Allgemeine Geschichte der Romans (Jena, 1850); and Alexi Chas' nag's Histoire du Roman, et de ses Rapports avec l'Histoire (Paris, 1872). To these may be added D. Masson's British Novelist and Their Styles (Camb. 1898); W. N. Sonigen, Essays on Fiction (1894); Landan's Beitrag zur Geschichte der Italienischen Novelle (Wien, 1875), and Quoted ed. Strunk's Sources and Originals (New York, 1948, 3d ed. 1972). A detailed bibliography is given in R. M. Cary's Dictionary of the International Bibliography of literary museums, public libraries, and private collections and exhibitions, 1926-40, and in the bibliographies of modern fiction. See also E. C. Trenholme's Bibliography of Early English Fiction, 1733-1789 (Oxford, 1924), and the Dictionary of National Biography (1885-1920). A. J. Smout's Novels of the Nineteenth Century (1909) is an excellent study of the development of the novel in the 19th century. See also the bibliographies of the British and American novelists, referring for details and criticisms to the articles on each of them.
in the 11th century, and built on the model of St Sophia at Constantinople, possessing some remarkable paintings and tombs; several others of more than thirty churches; and wall surrounding the Kreul. There is a little trade, but hardly any manufactures. Pop. (1885) 20,000.—The government, which lies immediately east of that of St Petersburg, has an area of 47,236 sq. m. and a pop. (1885) of 1,213,038. It has some 3000 lakes and many marshes. Three-fifths of this area is covered with forest.

**Novi**, a town of Italy, 30 miles NW. of Genoa, by rail. Pop. 9917. Here in 1799 the French were defeated (15th August) and victorious (6th November).

**Novihazar** (also Jenipasur, sometimes Raseia), the capital of a sanjak, situated on the river Rashka, an affluent of the Morava, 120 miles SE. of Bosna Serrl. Pop. 12,000. The sanjak of Novihazar (3842 sq. m.; pop. 168,000) is mountainous and barren, but as lying between Servia and Montenegro is of strategic importance. The western part is occupied by Austria; but the civil administration is nominally at least reserved to the Porte.

**Novgorodievsk**, a Russian fortress of the first rank, on the Vistula, 20 miles NW. of Warsaw. With Warsaw, Ivankov, and Brest Litovsk, it constitutes the Polish Quadrilateral.

**Novorossisk**, a fortified port on the Black Sea, to the SE. of Amapa in Russian Caucasus; the completion of a projected railway to Tarazitin on the Volga would make it command the Volga trade. A harbour and quay were begun in 1890. Pop. 1988.

**Novotcherkass**, a town of southern Russia, capital of the province of the Cossack of the Don, on the Aksai, a tributary of the Don, 40 miles from the Sea of Azov, a distance of 12 miles from its right bank, and about 70 miles ENE. of Taganrog. The central administration of the territory was transferred hither from Tcherkass in 1805; but the choice was not a happy one, the distance of the town from the Don, the great commercial artery, being much felt. Drinking-water has since 1867 been brought by an aqueduct 18 miles long. Pop. 58,700. Industry, agriculture, cattle-breeding, fishing, wine-growing, and the making of candles and bricks.

**Noyades** (Fr., 'drowns'). See Carrier (Jean).

**Noyan**, See Liqeur.

**Noyes, J. Humphrey.** See Perfectionists.

**Noyon**, a town in the French department of Oise, 67 miles NNE. of Paris by rail. It has a fine cathedral in the Transition style of the 12th century, an hôtel-de-ville (1483-1523), and a former episcopal palace. Pop. 5733. The Nouvauvam of Cesar, Noyon was a residence of Charlemagne and Hugo Capet, and the birthplace of Calvin. See Lettranc, Histoire de Noyon (Paris, 1888).

**Nubia** is a comparatively modern name for a large region in Africa, bounded by the Nile in the north, the Red Sea in the east, and the desert on the west. Nubia Proper, or Lower Nubia, extends from Assuan on the Egyptian frontier to Dongola; beyond that is Upper Nubia, properly applicable to a section of Upper Nubia, has come to be used for Nubia in its widest sense, together with the once Egyptian territory actually in the Sudan, and the equatorial provinces (see Soudan, also Nile). Under the Pharaohs Nubia was called Kush, but under the twentieth dynasty it was recovered by a series of native rulers, who adopted the civilisation of the Egyptians, and at a later date were Christianised (see Ethiopia). At present the country is occupied by races belonging to several different stocks, which have in most cases become mixed much in blood. The chief elements are Arab, more or less mixed with Nilotic and negro elements. There were Nubia, the Akhs, and Bisharin between the Nile and the Red Sea; and Nubas and Barabara in Lower Nubia, on and near the Nile between Assuan and Dongola. The Semitic Arabs are comparatively recent invaders to this region. They entered Nubia after occupying Egypt in the 7th century. For a few months the Christian Dongolawi kings till the 14th century, when the Arabs, assisted by a large contingent of Bosnians, became masters of the land. Presumably, the aboriginal negro population and tongue have been gradually modified by the admixture of Hamitic and Semitic elements. The various tribes, most of them active and warlike, are Moslems by faith, and till 1820 were ruled by their own chiefs. In that year Ismail Pasha made Nubia an Egyptian territory; and till 1881 it shared the fate of Egypt. For its later history, see Egypt, Soudan. The Nile is the most important feature of the country, and its only exception to the general aridity is the narrow strip of country on both sides of the Nile, which nowhere exceeds four miles in breadth, and in many places is only a quarter of a mile wide. The most fertile part is near Dongola. A mountain barrier extends across both sides of the Nile, and consists of granite and sandstone.

**Nucleobranchiata**, or Heteropoda. See Gastropoda.

**Nucleus**, See Cell.

**Nudibranchiata**, See Gastropoda.

**Nueva Esparta.** See Margarita.

**Nuevitas**, a port of entry of Cuba, on an extensive and irregular bay of the north coast, 50 miles by rail ENE. of Puerto Principe. It has considerable importance, exporting sugar, molasses, honey and wax, &c. Pop. (1890) 4228.

**Nuisance**, in English legal language, is used to denote whatever causes hurt to one's neighbour, or impedes him in the enjoyment of his property or the exercise of his liberties. A nuisance is either private (e.g. the creation of noxious vapours which make a neighbour's house unhealthy) or public (e.g. the diffusion of noxious vapours in a populous neighbourhood). It is not every slight annoyance that is described in law as a nuisance; there must be some serious interference with the property, health, or comfort of the party who complains. The remedies provided for this form of wrong are various. A court of common law would entertain an action for the recovery of damages; courts of equity went a step further, and 200 years ago a right of injunction was granted, so to be continued. An injunction may be obtained pending the trial of an action, and it is usual to apply for an injunction in any case where immediate relief is desired. Where the nuisance is injurious to health or life, and where it amounts to obstruction of a right of way, the injured party may apply (remove) the nuisance without resorting to a court of law; but in doing so he must take care not to
cause unnecessary disturbance or destruction of property. Where the nuisance is public an indictment will lie. If a highway, for instance, is in a dangerous state for want of repair, an indictment lies against the parties who are bound to repair it; but if an individual has suffered special damage, over and above declaring their right and intention, may bring an action. These legal remedies are now reinforced by the extensive powers conferred on local authorities. The acts passed for the removal of nuisances are now consolidated in the Public Health Act, 1875. Sanitary authorities (the guar- dians in rural areas, and the police or local board in towns) are empowered to appoint inspec- tors and medical officers, and to take measures for the removal of nuisances. The act contains an elaborate code of rules in regard to sewers, privies, ditches, gas-works, cellars, common lodging-houses, offensive trades, sale of unsound meat, infectious and epidemic diseases, &c. By-laws may be made by the local authority in regard to these matters; such by-laws require to be confirmed by the Local Government Board. Besides the provisions of the Public Health Act, 1875, there are many by- resolutions to be even summarised within our present limits, there are other acts which empower local authorities to deal with alkali-works, chimneys emitting black smoke, and other forms of nuis- ance. The Rivers Pollution Act, 1876, was in- tended to prevent the fouling of our rivers. Specific acts have been passed for the metropolitan district and for the river Thames; and the local acts which have been obtained by town-councillns and other public bodies; make numerous additions to the already complicated rules of the general law. For the enactment in regard to the suppression of brothels, see PROSTITUTION.

In Scotland the remedies provided in cases of nuisance are substantially the same as in England; and the Public Health Act of 1867 consolidates the statutory powers of local authorities. As to Ireland, see the Public Health Act of 1878. The United States law closely follows the English law; in the legislation of some states the term is used in a narrower sense to denote houses of ill-fame, &c. The powers of munici- pal authorities are de- fined by the law of the state to which they belong.

Nukha, a town of Russian Transcaucasia, in Elizabethpolis, is on the southern slope of Can- in and is 120 miles N. E. of Tiflis. Pop. 2500.

Nullification, in the history of the United States, refers especially to the action of the legis- lature of South Carolina in 1832, declaring certain acts of congress unconstitutional and therefore null and void. In 1828 congress passed what became known as the "tariff of abominations," which discriminated unfavourably against the people of the southern states. There cotton was the staple product, and any step tending to impose restric- tions on the commercial intercourse with Europe, where its principal markets lay, was bitterly opposed; whereas in the north, with its manufac- turing interests, the protective system policy has steadily grown in favour. In 1832 congress readjusted the tariff, modifying some of the objectionable features, but still leaving the southerners unjustly treated. In November a state convention in South Carolina passed an ordinance nullifying the tariff of 1828 and 1832, and declaring the equal of the state. The in the event of any attempt at coercion, to withdraw from the Union and organise a separate government. In December President Jackson (q.v.) issued a vigorous proclamation against the ordinance of South Carolina and, when South Carolina replied with a counter-proclamation, and volun- teers, in addition to the state militia, were or- ganised to resist the national government. But in

February 1833 Clay, the "great pacificator," intro- duced a Compromise Bill, providing for the gradual reduction by the year 1842 of all higher duties to 20 per cent.; congress passed this on March 2, and on March 15 the South Carolina convention re- pealed the ordinance of nullification and secession. See CALHOUN, John C.; JEFFERSON, Thomas; NUISANCE; and TROOP, "The movement of which this movement grew, see STATES' RIGHTS.

Nurnantia, the chief town of the Celtiberian people called Arveni, in Hispania Tarraco- nensis, was situated on a steep hill on the Durins (Donoro), in the neighbourhood of the present Soria in Old Castile. The site is probably marked by the present Populonia or Guignar. Nurnantia is cele- brated for the heroic resistance which it made to the Romans. After a siege of fifteen months, in the course of which famine and the sword had left alive very few of its 8000 brave defenders, it was taken and destroyed by Scipio the younger, 154 B.C. Scipio's army numbered no fewer than 60,000 men.

Numa Pomphilus, in the legendary history of Rome, its second king, the successor of Romulus. He was a native of Cures in the Sabine country, and was universally revered for his wisdom and piety. Unanimously elected king by the Roman people, he soon justified by his conduct the wisdom of their choice. After dividing Italy between himself and Romulus he proceeded, with the assistance of the nymph Egeria, who gave him interviews in a grove near the city, to draw up religious institutions for his subjects, and thus stands out in the primitive legend as the author of the Roman ceremonial law. His reign lasted for thirty-nine years, and was a golden age of peace and happiness.

Numbers. See PENTATEUCH, BIBLE, APOCAL- LYPTIC NUMBER.

Numbers, Theory of, the most subtle and intricate, and at the same time one of the most extensive branches of mathematical analysis. It treats primarily of the forms of numbers, and of the properties at once deducible from these forms; but its principal field is the theory of equations, in as far as equations are soluble in whole numbers or rational fractions, and more particularly that branch known as the Diophantine Analysis. Clearest of all to this branch are those problems which are usually grouped under the Diophantine Analysis (q.v.), a class of problems alike interesting and difficult; and of which the following are examples: (1) Find the numbers the sum of whose squares shall be a square number; (2) Find three square numbers in arithmetical progression; Answer, 1, 25, and 49; (3) and 12, 19; (4) and 100, 196, &c.

Forms of Numbers are certain algebraic formulas, which, by assigning to the letters successive numerical values from 0 upwards, are capable of producing all numbers without exception—e.g. by giving to m the successive values 0, 1, 2, 3, &c., in any of the following groups of formulas, 2m, 2m + 1; 3m, 3m + 1, 3m + 2; 4m, 4m + 1, 4m + 2; 4m + 3; we can produce the natural series of numbers. These formulas are based on the self- evident principle that the remainder after division is less than the divisor, and that consequently every number can be represented in the form of the product of two factors + a number less than the smaller of them. The following are examples of numbers.

By means of these formulas many properties of numbers can be demonstrated without difficulty. To give a few examples. (1) The product of two consecutive numbers is divisible by 2; Let 2m be one number, then the other is 2m + 1, and the product 2m(2m + 1) contains 2 as a factor, and is thus divisible by 2. (2) The product of three consecutive numbers is divisible by 6; Let
NUMBERS

3m be one of the numbers (as in every trial of consecutive numbers one must be a multiple of 3), then the numbers are: 3m; 3m + 1; or 3m + 2. In the first and third cases the proposition is manifest, as (3m - 2) (3m - 1) and (3m + 1) (3m + 2) are each divisible by 2, and therefore their product into 3m is divisible by 6 (= 1.2.3). In the second case the product is 3m² - 1, or 3m² - 3m + 3 (4m + 1), or 3m² - 3m + 3 (4m - 1), and it is necessary to show that m (9m² - 1) is divisible by 2; if m be even, the thing is proved; but if odd, then m² is odd, 9m² is odd, and 9m² - 1 is even; hence in this case also the proposition is true. It can similarly be proved that the product of four consecutive numbers, divisible by 24 (= 1.2.3.4), of five consecutive numbers by 120 (= 1.2.3.4.5), and so on generally. These propositions form the basis for proof of many properties of numbers, as that the difference of the squares of any two odd numbers is divisible by 8. The difference between a number and its cube is the product of three consecutive numbers, and is consequently (see above) always divisible by 6. Any prime number which, when divided by 4, leaves a remainder unity, is the sum of two square numbers; thus, 25 + 16 = 5² + 4², 233 + 106 + 64 = 13² + 8², &c.

Besides these there are a great many interesting properties of numbers which defy classification; such as that the sum of the odd numbers beginning with unity is a square number (the square of the number of terms added); i.e. 1 + 3 + 5 = 9 = 3²; 1 + 3 + 5 + 7 + 9 = 25 = 5², &c.; and the sum of the cubes of the natural numbers is the square of the sum of the numbers—i.e. 1³ + 2³ + 3³ = 1 + 8 = 27 = (1 + 2 + 3)³, 1³ + 2³ + 3³ + 4³ = 100 = (1 + 2 + 3 + 4)², &c.

Numbers are divided into prime and composite—prime numbers being those which contain no factor greater than unity, composite numbers those which are the product of two (not reckoning unity) or more factors. The number of primes is unlimited, and so consequently are the others. The product of any number of consecutive numbers is even, as also are the squares of all even numbers; while the product of two odd numbers, or the squares of odd numbers, is odd. Every composite number can be put under the form of a product of powers of numbers; thus, 144 = 2² x 3², or generally, a number n is the product of the number of its prime factors p and the number of the divisors of such a composite number is equal to the product (p + 1) (q + 1) (r + 1), unity and the number itself included. In the case of 144 the number of divisors would be 4 (1 + 1), or 5 + 3, or 15, which we find by trial to be the case. Perfect numbers are those which are equal to the sum of their divisors (the number itself being of course excepted); thus, 6 = 1 + 2 + 3, 28 = 1 + 2 + 4 + 7 + 14, and 496 are perfect numbers. Amicable numbers are pairs of numbers, either one of the pair being equal to the sum of the divisors of the other; thus, 220 (= 1 + 2 + 4 + 5 + 10 + 11 + 20 + 22 + 44 + 55 + 110 = 284) and 284 (= 1 + 2 + 4 + 71 + 142 = 220) are amicable numbers. For other series of numbers, see FIGURATE NUMBERS.

The ancient art of the theory of numbers was Diophantus, who flourished in the 3d century, and the subject received no further development till the time of Vieta and Fermat (q.v.), who greatly extended it. Euler next added his quota, and was followed by Lagrange, Legendre, and Gauss. They all contributed successfully to the study of numbers, and brought the theory to its present state. Cakenly, Libri, and Gill (in America) have also devoted themselves to it with success.

NUMERALS.

The invention of signs to represent numbers is doubtless much older than any form of writing. But the origin of counting, such as would involve the use of signs, is not so ancient or so generally held as might be supposed; even comparatively small numbers comes but late in the development from savage to civilized life. Even yet the aborigines of Australia work with only the numbers 1 and 2; 3 being 2 and 1 or 1 and 2; 4 being 2 and 2; and, as a rule, no number above 10. The Australian blinds count, as high as their earliest visible signs are doubtless the fingers held up; and the denary system of notation is due to the fact that we have ten fingers. The rude method of finger-counting has been developed into a highly-complicated system of reckoning, still in use in eastern Europe for the counting of horses and sheep. But the figures, when arranged in convenient and compact arrangements of the ten digits allowing of reckoning as high as 10,000. For permanent purposes a system of single strokes is the most obvious method; and series of strokes as high as four or five are found in various countries in old inscriptions. But, for practical purposes, the counting of the ten digits was the first step towards the convenient and confusing; hence additional symbols are found to make their appearance for 5, 10, 100, and 1,000.

In Babylonian inscriptions two Cuneiforms (q.v.) serve to express all the numbers from 1 to 100. The Egyptian scheme is alphabetic and illustrated at hieroglyphics (Von der Lühe, 1878), and from these hieroglyphs were derived the Phoenician, Palmyrene, and Syriac numerals.

After alphabetic writing was in use, the alphabetic signs obviously lent themselves to employment in numbers—either by substituting the order of the letters, each having a successively greater value than its predecessor; or the initial letter of the word for the several numbers might be used. Thus, according to the latter method, the Greek inscriptions used I for 1, ΙΙ (IImh) for 5, Ά (Δηαes) for 10, Η (the old sign for he, used also for the numbers of the Ionic alphabet) for 100, Χ (Ximplified) for 1,000, and Μ (Μενον) for 10,000. Then a II with a Α' inscribed in it stood for 50 (5 x 10), and with H inscribed (5 x 100) for 500. In this connection the capitals or uncial was used of course. Otherwise, following simply the order of the letters, the four last letters of the Ionic alphabet were used for the numbers 1 to 24; the books of the Homeric, for example, are often thus numbered. But a more ingenious method was soon adopted by the Greeks, as also by the Hebrews. The alphabet (cursive) was divided into three groups, of which the first did duty for the units, the second for the tens, the third for hundreds. The Hebrew square character had twenty-two distinct letters, and double forms for five of them, so that three groups, each of nine characters, were available. The Greek alphabet, as was ultimate than the Hebrew, required the three additional signs required to make up three nines were obtained by keeping two of the old Phoenician letters / or ή (see Digamma) for 6, and 5 or 4 (Kohph) for 90, and adding the superfluous oblique گ (Samii) for 300. There are thus 9 + 3 = 120, of which 3 for 90, 30 for 900, 90 for 9000; and of these 30, 300, and 9000 were used for expressing 1000, 10,000, and 100,000. The thousands were made by inscribing an under the units; thus 98 was 1000; 9,000 was 1000; 99 was 8900; and 999 was 8990. The Use of the capitals is familiar enough to ourselves yet. The C has been understood to be the initial of centum, and M of mille. But some (as Canon Taylor) contend that the Latinas, when they dropped the Greek
phi, chi, and theta as phonetic signs, retained them as numerals, with arbitrary values. In this case the C would be only, finally e assimilated to C, because C was the initial of centum. The old D, used for 1000, came to be written CI, afterwards confused with β or M, the initial of mille. The L would be a derivative from an old Chalcidian form of chi, inscribed for lapidary purposes L, and then simplified to I, and finally to C, because the theory of the dropped Greek letters suppose that M is from a circle with a vertical stroke, the C a circle with a horizontal stroke or a cross, \( \Theta \). The X, V, and L might all come from this letter. In any case, X is twice \( \chi \) (whether or not the latter originated in the hand held with the thumb to one side and the other fingers together); and D (for 500) or I) is half C[). See the articles in this work on the letters C, D, L, and M.

It is doubtful how far the Abacus (q.v.) has to do with the development of the system of numerals, in which the value depends on its position. There were abacus boards so arranged that the first column meant units, the second tenths, the third hundreds, the fourth thousands; or, conversely, a method of writing numbers derived from abaci, as used in Egypt. Europe in the middle ages; we show the columnar arrangement simplifying the reading in the several cases, 5, 6, 530, 604, 54.

In the decimal scheme of figures as now used by us, the nine numerals with the zero, which enables the value of the position to be secured without commas or columnar arrangement, are known as the Arabic numerals, but are unquestionably of Indian origin. From India they were apparently brought to Egypt by the middle of the 8th century, and their value and use was set forth early next century by the Arab mathematician Abu Ja‘far Mohammed ben Musa, or Al-Khwarizmi (\"native of Khwarizm, –Khiva\") whence the system came to be known in Europe, where it became familiar in the 12th century, as an \"Algorism\" or \"Algorithm.\" The earliest European forms of these characters are found in MSS. of the 12th century; by the 14th they were practically of the same shape as now. The 12th century numerals are evidently forms of the Gobar or western Arabic numerals used in

Persia in the 10th century. These can be traced to the contemporary Indian Devanagari numerals, which again are as certainly based on an old series of characters used in cave-inscriptions in the 1st and 2nd centuries. These Canon Taylor contents are (mainly, at least) degraded forms of the Indo-Iranian alphabet. See Alphabet, Vol. I, p. 188. The modern arithmetic was not practised in England till about the middle of the 15th century, and for a long time after its introduction was taught only in the universities.

The decimal system, possessing only nine symbols—viz. 1, 2, 3, 4, 5, 6, 7, 8, 9 (called the nine digits)—adopts the principle of giving to each symbol or \"figure\" two values, one the absolute value, and the other a value depending upon its position, a figure moved one place to the left being held to be increased in nine times ten. When an old D is used to mean (6 times 1000) + (4 × 100) + (7 × 10) + (3 × 1); and 6004 becomes (6 × 1000) + (4 × 1). In this latter instance the peculiar importance of the figure 0 is seen (see DECIval SYSTEM).

It should be mentioned that European nations do not all read the numerals in the same way, as regards larger numbers. Let us take the figures 56,084,763,204,504; these, read after the fashion of the French and other continental arithmeticians, are fifty-six trillions, eighty-four billions, seven-hundred-and-sixty-three millions, two-hundred-and-four thousand-significant for the nineteenth and twentieth centuries. So also in America. In Britain, instead of billions, we have, according to the current usage, thousands of millions; after this, tens of thousands of millions and hundreds of thousands of millions, and then billions, which are the same as the French trillions. The above number, according to the British mode, would be read fifty-six billions, eighty-four thousandseven-hundred-and-sixty-three millions, two-hundred-and-four thousands, five-hundred-and four units. The British trilion has nineteen figures, the continental trilion has twenty.

As to the Indian origin of our numerals, see Canon Taylor, The Alphabet (1853; vol. ii, p. 203-298); Wepko, Memorie sur la Propagation des Chiffres Indiens (1863); Barnett, South Indian Paleography (1874); Treuttiein, Geschichte unserer Zahlenzeichen (1873).

Numidia (Gr. Nomadia, \"land of Nomads\"), the name given by the Romans to the north coast of Africa, corresponding to some extent with the modern Algeris, and lying between Mauritania and the Roman province of Africa; on the south it reached to the chains of Mount Atlas. The inhabitants of Numidia, as of Mauritis, are all descended from a race from which the modern Berbs are descended. They were a warlike race, and excelled as horsemen, but were proverbially faithless and usurious. Of their tribes the Massyli in the east and the Massassylifi in the west were the most powerful. In the grand struggle between the Carthaginians and the Romans they at first fought on the side of the former, but subsequently the king of the Eastern Numidians, Massinissa, joined the Romans, and rendered them effectual service in the war with Hannibal. He was afterwards called Constantine, a name still preserved in Constantine. The modern history of Numidia, see Algeris.

Numismatics (Gr. nomismatikos, from nomos, \"law\", \"a legally current coin\") is this science which embraces the study of the current coins of all nations. In the wider, though less accurate, acceptation of the term it includes also that of medals, both artistic and historical. The various branches of numismatics are (1) Greek, Phocianic, &c.; (2) Roman, and its successor, the Justinianic; (3) Mediaeval; and Modern; and (4) Oriental. The chief value of numismatics consists in the light which coins throw upon history. The secondary importance of the science is purely artistic. The study of coins is also of great use in the science of the numismatics, in fixing the chronology of the different systems of alphabetical writing
NUMISMATICS

(Paleography), and in indicating the origin and gradual extension over the civilised world of the principal systems of weighing the precious metals (Metrology). Historically, coins are of the utmost importance as being contemporary and authentic documents furnishing us with in many cases, the most accurate names of obscure cities and peoples, together with the chronological succession of their kings, tyrants, or chief-magistrates. Artistically, they faithfully record the successive phases of art from its earliest beginnings to its culminating point, and through all the evolution of its forms, the trend of revival, and second decadence, to the present day.

1. Greek Coins.—The use of the precious metals as mediums of exchange may be traced back to the remotest ages of which we possess any historical accounts. Thus, for instance, we read that Abraham was ‘very rich in cattle, in silver, and in gold’ (Gen. xiii. 2; xxiv. 35), and in the account of his purchase of the cave of Machpelah (Gen. xxviii. 16) it is stated that ‘Abraham weighed to Ephron four hundred shekels of silver current with the merchant.’ This use of gold and silver as weights and measures may have originated in the balance, must, however, be carefully distinguished from its use as ‘coin,’ a word which implies that the ingot or piece of metal is impressed with an official device, mark, or ‘type,’ serving the purpose of a guarantee of just weight and value. ‘So far as we have any knowledge,’ says Herodotus (i. 94), ‘the Lydians were the first nation to introduce the use of gold and silver coin.’ The adoption of this apparently simple means of facilitating exchanges appears to have been due in the first instance to the custom of depositing treasure for safe custody in the sacred temples of the city, while the precious metal, whether in gold or silver, committed to the care of the priests, were consecrated to the local divinity by being impressed with a badge or symbol, usually the head of some sacred animal. These pieces of metal were subsequently put into circulation, the sacred badge being known and accepted in the district as a reliable guarantee of value. The earliest Lydian coins which have been handed down to our times belong probably to the reign of Gyges, who ascended the throne about 700 B.C. They are bean-shaped lumps of the natural Lydian gold ore, which were stamped and countersunk, and went by the name of electrum or pale gold. The face or obverse of the coin bears the figure of a lion, the sacred symbol of the goddess Cybele, and the reverse consists merely of the impress of the rude unmachined punch or nail-head which served to keep the ingot in its place while it was being struck. The ingot, held in position by a pair of tongs, was placed on this square nail-head, and on the top of the ingot the engraved die was laid while the moulder struck it with successive blows of a heavy sledge-hammer until the impressions of the die were transferred to the silver or the electrum. These nail-heads on the reverse were brought into sufficient relief and intaglio respectively.

These one-sided coins with an intaglio or ‘incuse’ square on the reverse are characteristic of the early stages of the art of coining not only in Lydia, but in all the Greek cities, for the use of coined money rapidly spread from Lydia over all the coasts and islands of the Aegean Sea, each city issuing money bearing the symbol of its local divinity. In Greece proper the earliest coins were of silver, and are said to have been struck by Philetai, king of Argos. These Greek coins were in a crude state, sacred to the goddess Aphrodite, in whose temple at Aegina these earliest Greek coins were issued. On this occasion it is related that Philetai hung up in the temple of the goddess Hera at Argos specimens of the embossed bronze and iron bars, which served the purpose of money before his time, in memory of the old order of things. From the time of Philetai onwards the coinage of Greece and of the East may be classified historically in the following eight periods:

(i.) 700-480 B.C.—Period of archaic ending with the first money. The earliest coins of these two centuries are characterised at first by a rude strength of style, and afterwards by a gradual development into clearly-defined forms, which, however, are always distinguishable by their angularity and stiffness from the freer work of later times. For instance, every example of a human face is always drawn, even when in profile, as if seen from the front; both corners being visible, while the mouth wears the fixed and formal smile with which we are familiar on the Egyptian monuments. Towards the end of the archaic period a type in relief begins to appear within the incuse square of the reverse. The coins which circulated most widely were, in silver, those of Aegina with the tortoise above referred to; the tetradrachms of Athens, first introduced by Solon 590 B.C., obverse, head of Athena, reverse, owl, the sacred bird of the city, the famous Darics, on which the Persian king is represented as a kneeling archer. In the west the chief coins were those of the Greek colonies in Southern Italy, Sybaris, Croton, Tarentum, &c., which differ from those of Greece proper in having the figures on the reverse in intaglio instead of in relief.

(ii.) 480-400 B.C.—Period of transitional and early fine art, to the end of the Athenian supremacy.

The coins of this period are characterised by a great advance in the technical skill with which the dies were handled, and the finish of the gold or silver. The name of the city or of the chief magistrate now occurs frequently on the reverse, usually in an abbreviated form.

In Asia Minor the chief coinage of this period is the electrum currency of the flourishing commercial city of Cyzicus on the Propontis, so-called to under the name of ‘Cyzene staters’ by Xenophon and other historians. In Greece proper the Athenian money was still the chief, though by no means the only medium of exchange, and in the West the Corinthian staters, with the figure of Pegasus on the obverse, circulated. This coin affords a larger variety of types than any other Greek city, though the finest specimens of the Syracusan monetary art fall into the next period.

(iii.) 400-336 B.C.—Period of finest art, age of the Spartan and Theban supremacies, and of Philip of Macedon.

The art of die-engraving attained in this period a higher point of excellence than it has ever since reached. The coin-types are remarkable for sculptur-esque reserve, intensity of action, or rich and varied ornamentation, according to the requirements of the subject represented. The heads are mostly ideal heads of divinities on the obverses, and mythological figures on the reverses, or agonistic types referring to the local games and religious festivals, such as the victorios quadrigae on the famous Syracusan medallions, which are generally recognised as the finest and most beautifully executed coins that have ever been struck. In this age the practice of coining money had become universal; the number of mints throughout the civilised world was enormous, every little town striking its own ‘autonomous’ silver or bronze, and, in some cases, gold. In old Egypt, under the successors of Philip of Macedon, obtained a wide circulation, and his conquests in Greece gradually put an end to the independent issues in that country.

(iv.) 336-280 B.C.—Period of later fine art; age of Alexander the Great and the Diadochi, charac-
terised by the introduction of the portrait of the reigning monarch in place of the head of the godess of the divinity on the obverse.—Before Alexander's time no coins of his worthies, except in the west, which was beyond the sphere of Alexander's conquests, and where the cities of Italy and Sicily continued to strike gold and silver until they were in turn brought under subjection by the growing power of Rome (below).  

(vi. of p.) 290 B.C. to the Christian era.—Periods of early and later decline; age of the Epigoni, the Attalids, and of Mithridates the Great.—The silver and gold coinage during these three centuries is almost exclusively regal, and presents us with a remarkable series of lifelike portraits of the long succession of the Seleucid kings of Syria, of the Ptolemyes of Egypt, of the kings of Macedon, of Pontus and Bithynia, of the Attalids of Pergamum, and of the successors of Alexander in Northern India, many of whom are known to us only from their coinage. The chief characteristic feature of the art of numismatic portraiture, which attained its highest perfection about 250 B.C., is its realism, which is carried in some cases almost to the verge of brutality, as for instance on the tetradrachms of some of the kings of Pontus, the anonymous king of Mithridates the Great. It is to this period that the earliest coins of the Jews belong—the well-known shekels of Israel, struck at Jerusalem by Simon Maccabeus, 143-135 B.C. Among the latest portraits on Greek coins is that of the famous Cleopatra on a coin of Ascalon. She is represented with wide-open and eager eyes, a prominent and slightly aquiline nose, and a large and expressive mouth, but with none of the seductive beauty which we would expect to find on the coins of this fascinating princess. Among the non-regal coins of the 21st century B.C. the large tetradrachms of some of the Greek cities of the western coast of Asia Minor, which regained their freedom after the defeat of Antiochus the Great by the Romans, 104 B.C., are worthy of note; those of Cyzicus, Myrina, Smyrna, and Magnesia being especially remarkable. Throughout the greater part of this period Athens continued to coin very plentifully her tetradrachms with the helmeted head of the chryselephantine statue of Athena Parthenos by Phidias on the obverse. These coins formed the chief currency for the trade between Europe and the East.  

(viii.) From the Christian era to the reign of the Emperor Gallienus.—During this period of nearly three centuries the Romans permitted the Greek cities of Asia to mint half the amount of both bronze and silver money for local use. It is known to collectors as the 'Greek imperial' coinage. Artistically it is quite without interest, but archeologically it is perhaps more important than the matchless silver and gold currency of the free and independent cities of the ancient world. The imperial coins illustrate the local festivals, religious rites, and municipal institutions which prevailed in the outlying provinces of the Roman empire, and are also of value as recording the names of the successive chief-magistrates and high officials of the various cities, who appear to have been responsible for the coinage in each locality.  

II. Roman and Byzantine Coins.—The Romans for the first four centuries of their history had no regular coinage, the chief medium of exchange being bronze, circulating by weight, aes rude, in humps of irregular form. It was probably about the middle of the 4th century B.C. that the pound-weight of bronze (12 oz.) was first cast into large unwieldy pieces of circular shape, aes gravis, having on the obverse a head of Janus, and on the reverse the prow of a galley. This was the Libra; and its divisions were the Semis (6 oz.), the Triens (4 oz.), the Quadrans (2 oz.), the Sextans (2 oz.), and the Uncia (1 oz.), each of which bore a distinct type and mark of value. As time went on the As was gradually reduced in weight until (circa 264 B.C.) it stood at no more than 2 oz. At this point the law stepped in and endeavoured to check the further debasement of the coin by fixing the weight legally at 2 oz. (sextantal reduction), and by issuing for the first time a silver coin, the Denarius, equivalent to ten asses. The fractions of the silver piece were the Quiniarius (five asses) and the Sestertius (two and a half asses). In 217 B.C. the weight of the As was further legally reduced to 1 oz. (uncia reduction), and again in 89 B.C. to half an ounce (semisemimal reduction). All these successive reductions were financial expedients, the object of which was to bring a little order into the state currency, which continually tended to become more and more deteriorated. The types of the silver coins, at first constant and uniform, were subsequently varied according to the pleasure of the tribunviri monetales, as the officers were called who were entrusted with the supervision of the coinage. The long series of the Republican silver money, which extends from 264 B.C. to Imperial times, is now incorrectly known as the Consular or Family series, because the types usually allude to events connected with the family history of the triunviri monetales. The Imperial series commenced in 2 B.C., when Augustus abolished the office of the monedarii and reserved for himself all rights connected with the coinage of gold and silver, though leaving to the senate the privilege of striking bronze, which was henceforth distinguished by the letters S.C. (Senatoris Consulti). All coins now bore the portrait of the emperor, or of some member of the imperial family, and on the reverse, for the most part, allegorical personifications, representations of historical events, architectural monuments, or public buildings. Their inscriptions furnish us with the exact date of issue. The chief denominations were, in gold, the aureus; in silver, the denarius; and in bronze, the stertius (now known as the large bronze), tarified at four asses; the dupondius (middle bronze), two asses; and the as and its divisions (small bronze). The large bronze from Augustus to Commodus supplies us with a magnificent series of imperial portraits, but from Septimius Severus onwards there is a rapid deterioration both in art and workmanship. From the reign of Caracalla to that of Diocletian the utmost disorder prevailed in the coinage, each successive
numismatics

emperor debasing it more and more, until the 8th century became during the copper coin washed with tin. In 296 A.D. Diocletian entirely reforged the currency, which was again modified by Constantine, who reduced the weight of the aureus from sixty to seventy-two to the pound. The new gold piece was henceforth known as the solidus, and it maintained its full weight and purity of metal as long as the empire lasted. This coin received in western Europe the name of Bezant or Byzant, from Byzantium or Constantinople, the capital of the eastern empire. The types of the coins of the Christian emperors retained for some time the Christological ideas of the eastern issues. Little by little Christian symbolism crept in, until at length all pagan influence disappeared, and figures of Christ and the Virgin took the place of the allegorical representations of pagan times. The Latin language in the inscriptions on Byzantine coins continued to be used until the latter part of the 11th century, when it was finally displaced by the Greek.

III. Medieval and Modern Coins.—The coinage of western Europe, down to the time of Charlemagne, consisted mostly of imitations of the Byzantine issues. The Carolingian ducat (A.D.) produced a new silver coin called the denier, which soon came into general use.

English.—The denier was introduced into England, under the name of the penny, by Offa, king of Mercia (ob. 794), previous to whose time the currency of the Anglo-Saxons had consisted of small silver coins (seclittas) and copper coins (stycas), which were rude copies of the Merovingian money. Under the Anglo-Saxon and early Norman kings local mints were established at all the considerable towns in England, and the penny bore on its reverse, the name of the town and of the moneyer by whom it was struck. The earliest English gold coins were struck by Henry III., but gold money did not come into general use until the reign of Edward III., who introduced the gold noble (6s. 8d.) and the gold moria (6s.), with their divisions. This king also first struck multiples of the penny, groats (4d.) and half-groats. Edward IV. added new denominations called the rose noble and the angel, so called from its type, St Michael slaying the dragon. With the accession of the Tudor dynasty authentic portraits of the reigning sovereigns appear on the coins of the realm, and many new denominations, such as halfpenny or sovereign in gold, and crowns, half-crowns, shillings, &c., in silver, were added. In the time of Charles I. we note a remarkable improvement in the art of die-engraving, of which the celebrated Oxford crown is a good example; on the obverse of which is the king on horseback, with a view of the city of Oxford in the distance. In this reign a Frenchman named Briot, employed in the English mint, introduced the use of the mill and sanguy. On the coins of the Commonwealth the inscription, the name of the reigning sovereign, and some of Cromwell’s portraits by the famous engraver, Thomas Simon, are worthy of the highest praise. To the series of Charles II. belongs the beautiful Petition crown, also by Simon. This coin bears Simon’s petition to be reinstated as engraver to the king, on the edge: ‘Thomas Simon most humbly prays your majesty to compare this, his trial piece, with the Dutch, and if more truly drawn and embossed, more gracefully ordered, and more accurately engraved, to receive him.’ Edward II.’s reign the first quinaries were struck from gold brought from the Guinéan Coast, and copper coins, consisting of halfpencey and farthings, were first regularly established. From this time onwards the English coinage declines very greatly in artistic interest, George IV.’s crown by Plistrucci being perhaps the only modern piece worth noticing.

Scottish.—The coinage of Scotland down to the reign of Robert III. followed closely the English types. From this time original designs became more frequent. It reached its highest point of artistic excellence in the reigns of James V. and Mary; and few modern pieces are more beautiful than the bonnet-piece of the former, representing the king wearing a bonnet, and the ryal of the latter, bearing the queen’s portrait in profile.

Irish.—The earliest Irish coins were struck by the Danish and Norse invaders, 929–1069. They bore the name of the reigning sovereign, from the counties of their restoration. After this we have no Irish coinage until the partial conquest of the country by Henry II., in whose reign mints were established at Dublin, Cork, Drogheda, Limerick, Trim, Waterford, and Wexford. Among the more modern Irish coins the gun-metal money of James II. is historically interesting. This was ‘money of necessity,’ struck after his flight from England. It was decreed in the reign of William and Mary, and redeemed only at metal value.

Western Europe.—The mediaeval and modern coinage was issued in various European states, from the time of the issue of the new denier by Charlemagne in the 8th century down to the middle of the 17th century, is no less interesting than that of Britain. The Italian and Papal coins are artistically superior to the rest, especially in portraiture, where the influence of the Renaissance of art may be clearly traced. An important landmark in the numismatic history of western Europe is the re-introduction of gold money, dating from the first issue of the florin d’oro in Florence, 1252. In France the coins of Francis I. and Henry II., and of the German Emperors, are especially noteworthy; some of the latter being ascribed to the hand of Albert Dürer. Many of the later German thalers are also of considerable historical value, as their types record the chief events in the history of the cities by which they were struck.

IV. Oriental Coins.—Oriental coins fall into three principal divisions: (1) The coins of India beginning with those of the successors of Alexander, the Great in the 3rd century B.C. in Bactria and the Punjab, and extending down to recent times. (2) The coins of the other countries of the Mogul empire, which are: especially the gold mahurs and silver rupees of Jehangir with the signs of the zodiac engraved in bold relief. (3) The coins of the numerous Arab dynasties in Asia, Africa, and Spain, consist of dirhams in gold and dirhems in silver. The interest of these Mahometan issues is purely historical, as they bear no representations of living beings, all such images being forbidden to true believers. Many of these coins possess, however, a beauty of their own, as seen in the coins of the Pathan Kings. The inscriptions consist of formulae of the faith from the Koran, together with the name of Calip, the place of mintage, and the date of issue. The Kufic coins are the subject of a special article.

(1) The coins of China, Japan, and the Far East. — The coins of China begin in the 7th century B.C., the earliest being in the form of tools, such as adzes, chisels, spades, knives, &c. In the 1st century B.C. these pieces are replaced by circular discs of brass called cash, with a square hole in the centre, a form of coin which has survived until our time in the region. The Japanese coins begin about the 7th century A.D., and are modelled on the Chinese pattern. Among the more modern Japanese issues are old pieces of gold and silver, and large oval pieces, called obo-an.
NURAGHE

Nun (A.S. *nunna; Low Lat. nunna or norba, 'mother'; Gr. *nunâē, neina, 'aunt'; Sansk. *nanda, a familiar word for ‘mother,’ corresponding to Sansk. tátē, ‘father’), a member of a religious order of women. The general characteristics of the religious orders will be found under the head Monasticism, and expressly enumerated in the list of religious orders. Of arrangements peculiar to the religious orders of women the most striking perhaps is the strictness in the regularly authorised orders of nuns taking solemn vows, nuns of the ‘cloister,’ or enclosure, which no extern is ever permitted to enter, and in which orders are never permitted to pass, without express leave of the bishop. The superiors of convents of nuns are called by the names Abbess, Prioress, and, in general, Mother Superior. They are, ordinarily speaking, elected by chapters of their own body, with the approval of the bishop, unless the convent be one of the class called exempt houses, which are immediately subject to the authority of the holy see. The ceremony of the solemn blessing or inauguration of the abbess is reserved to the bishop, or to a priest delegated by the bishop. The authority of the abbess over her nuns is very comprehensive, but a precise line is drawn between her powers and those of the priestly office, from which she is strictly debared. The name of nun is given in general to the sisters of all religious congregations of females who live in retirement and are bound by rule; but it is principally and properly confined to the sisters of the religious orders strictly so called. In most cases, soon after the foundation of the orders for men corresponding orders have been established for women. The usages as to diet, fasting, clothing, &c., are very various in the different communities. The rule of life of each is a very important document: the question of which was enacted at the beginning of her novitiate is white; that of profession, given at the end of it, is black in some orders, white in others.

Nunc Dimittis, the name given to the canticle of Simeon (Luke, ii. 22-32), which forms part of the compline office of the Roman Breviary, and is retained in the evening service of the Anglican Church when it follows the second lesson.

Nuncio. See Ligate.

Nuncorun. See Hastings (Warren).

Nuddydroog (Naudidriog), a fortified hill in Mysore, 31 miles N. of Bangalore, and 4810 feet above the sea. The extensive fortifications on the plateau summit were erected by Hyder Ali and Tipu Sultan; they were stormed by a British force in 1791. The place is now used as a health-resort by Europeans from Bangalore.

Nuneaton, a market-town of Warwickshire, on the river Anker and the Coventry Canal, 14 miles NNW. of Rugby, 9 N. by E. of Coventry, and 22 E. of Birmingham. It has a good Gothic parish church, and remains of a 12th-century nunnery, with a modern church built thereon, and a grammar-school (1553). The ribbon manufacture has given place to worsted, cotton, and woollen spinning. "George Eliot," born at Arbury Farm, two miles to the south-west, was brought up here, and a stone with her name marks the spot. In the churchyard there was a monument to the poet described in Felix Holt, Pop. of parish (1881) 8465; (1891) 11,580.

Nuraghe, or Nurhag, the name of round towers, in shape truncated cones, of which 3000 are scattered about the island of Sardinia. They vary from 20 to 60 feet in diameter, rise 30 or 40 feet above the ground, and consist of domed chambers connected by a spiral staircase, and are made of granite, limestone, basalt, porphyry, sandstone, and schist, built in regular courses of roughly-hewn stone, without cement. Some of the stones in the lower courses weigh 12 tons each. Believed to be of Phoenician origin, they closely

NUMMULITES

and ka-bon, some of which are more than 6 inches in length. Like China, Japan has now adopted a currency modelled on the European pattern.

The standard works on Greek Numismatics in general are Eckhel's Doctrina Numorum (1792-98); Monnet, Description des Médailles grecques (1807-37); B. V. Head, Histoire Numismatique of Oxford, London, and several annually available on orders. Of arrangements peculiar to the religious orders of women the most striking perhaps is the strictness in the regularly authorised orders of nuns taking solemn vows, nuns of the ‘cloister,’ or enclosure, which no extern is ever permitted to enter, and in which orders are never permitted to pass, without express leave of the bishop. The superiors of convents of nuns are called by the names Abbess, Prioress, and, in general, Mother Superior. They are, ordinarily speaking, elected by chapters of their own body, with the approval of the bishop, unless the convent be one of the class called exempt houses, which are immediately subject to the authority of the holy see. The ceremony of the solemn blessing or inauguration of the abbess is reserved to the bishop, or to a priest delegated by the bishop. The authority of the abbess over her nuns is very comprehensive, but a precise line is drawn between her powers and those of the priestly office, from which she is strictly debared. The name of nun is given in general to the sisters of all religious congregations of females who live in retirement and are bound by rule; but it is principally and properly confined to the sisters of the religious orders strictly so called. In most cases, soon after the foundation of the orders for men corresponding orders have been established for women. The usages as to diet, fasting, clothing, &c., are very various in the different communities. The rule of life of each is a very important document: the question of which was enacted at the beginning of her novitiate is white; that of profession, given at the end of it, is black in some orders, white in others.

Nunnulites, or Nummulina (‘money-fossils’), a genus of fossil foraminifera, the shells of which form immense masses of rock of Eocene age. They are circular bodies of a lenticular shape, varying in magnitude from the merest point to the size of a florin or larger. The shell is composed of a series of small chambers arranged in a concentric manner. The growth of the shell does not take place only around the circumference, but each whorl invests all the preceding whorls, so as to form a new layer over the entire surface of the disc, thus adding to the thickness as well as the breadth, and giving the fossil a lettered form. A thin intervening space separates each layer from the one which it covers, and this space at the margin swells out to form the chambers. All the internal cavities, however, seem to have been occupied with the living sarcode, and an intimate connection was maintained between them by means of innumerable parallel tubuli, which everywhere pass from one surface to another, and which permitted the passage of the sarcode as freely as do the minute pores or foramina of the living foraminifera. The name is given to them from their resemblance to coins. The genus appears first in the Cretaceous system, where it is represented by one small form. Several species are also met with in the Jurassic and Cretaceous rocks, but the genus reached its maximum in Eocene times. It is represented at present by only a few small forms.

Nummulite Limestone, an important member of the Eocene system of southern Europe, &c., consists of a limestone composed of nummulites held together by a matrix formed of the comminuted particles of their shells, and of smaller foraminifera. It attains a thickness of several thousand feet, and has been traced over a vast area. It occurs on both sides of the Mediterranean basin, in Spain and in Morocco. It enters largely into the composition of the Apennines, the Alps, the Carpathians, and the Balkans; it extends through Greece, Egypt, and Asia Minor, and thence through Persia and the Himalayas to the coasts of China and Japan.
NUR ED-DIN MAHMÜD

MALEK AL-ABDEL,

emir and sultan of Syria, was born at Damascus in 1117 in his father's family. His uncle, originally governor of Mosul and Diarbekir under the Seljuk sultans, had established his independence, and extended his authority over northern Syria. Nur ed-Din Mahmud succeeded him in 1145, and changed the seat of government from Mosul to Aleppo. From this time onwards his life was one long duel with the Christians—the Crusaders, Hospitallers, Templars, and Knights of the Latin Kingdom of Jerusalem. The most notable incidents in this contest may be briefly summarised. Count Joscelin, in an attempt to recover his capital, Edessa, was signally discomfited under its walls, and his army almost annihilated. This gave occasion to the second Crusade. The Crusaders were, however, foiled by Nur ed-Din before Damascus, and, being defeated in a number of conflicts, abandoned their enterprise. The emir next conquered Tripolis and Antioch, the princes of the latter territory being defeated and slain in a bloody conflict in June 1149; and before 1151 all the Christian strongholds in Syria were in Nur ed-Din's hands. He next took possession of Damascus (which till this time had been ruled by an independent Seljuk prince) in 1153. About this time a terrible earthquake devastated Syria, levelling large portions of Antioch, Tripolis, Hamath, Homs, and other towns; and Nur ed-Din devoted all his energies to repairing the damage done. In 1157 the Christian orders suffered a severe defeat near Paneas; but an illness, which prostrated their enemy in 1159 enabled them to retake some of their lost territories. Recovering, Nur ed-Din soon won back what had been taken from him, and turned his attention to Egypt, then governed by the effeminate and degenerate Fatimids. In 1159, his brother, Ahmad, overran Egypt, but, dying soon afterwards, was succeeded by his nephew, the celebrated Salah ad-Din (q.v.), who completed the conquest of the country, and restored the Sunni faith. This won for Nur ed-Din the gratitude of the calif of Bagdad, who created him sultan of Syria and Egypt. Nur ed-Din, however, grew jealous of his able young lieutenant, and was preparing to march into Egypt in person, when he died at Damascus in May 1173. This prince is one of the great heroes of Moslem history. He was not a savage conqueror, but zealously promoted the cultivation of the sciences, arts, and literature, and established a strict administration of justice throughout his dominions; he was revered by his Moslems, and greatly respected by his Christian subjects.

Nuremberg (Ger. Nürnberg), a city in the Bavarian province of Middle Franconia, in a sandy but well-cultivated district, on the Little Pegnitz (a sub-affluent of the Main), 95 miles N. by W. of Munich. It is the residence of the Bisth. of Frankfort. It is the quaintest and most interesting town of Germany, on account of the wealth of medieval architecture which it presents in its many-towered walls, its gateways, its picturesque streets with their gabled house-fronts, its bridges, and its beautiful Gothic fountains. The city was first fortified by Welfs in 1123 by Conrad II. and Helmer Straten, and was subsequently greatly improved by Count Eberhard. The town wall, built (q.v. 1024-1158) by Conrad II. and Frederick Barbarossa, commands a glorious view of the surrounding country, and is rich in paintings and wood-carvings; in its courtyard is a coeval linden-tree. Of eight fine churches the two finest are St Lawrence (1274-1477), with two noble towers 233 feet high, exquisite stained glass, the famous stone tabernacle (1405-1500) by Adam Kraft, and the wood-carvings of Veit Stoss; and St Sebal’s (c. 1225-2377), with the superb shrine of Peter Vischer. Other noteworthy objects are the Italian Renaissance town-hall (1622); the new law-courts (1877); the library, founded by Melanchthon (1526); the Germanic museum (1852); an industrial museum (1871); a library of 70,000 volumes; Albert Dürer’s house; and the statues of him, Hans Sachs, and Melanchthon, with the ‘Victoria’

Schönbrunnen Fountain, Nuremberg.
city, which a century before had embraced the Reform ed doctrines. Still, in 1803 it was allowed to retain its independence, with a territory of 453 sq. m., containing 80,000 inhabitants; but, in consequence of disputes with Prussia, it entered into the Danish Confederation, and in 1806 was transferred to Bavaria.

See German works by Voigt (1862), Laechner (4th ed. 1873), Priem (1874), Stockbauer (1879), Roth (1884).

Nursery Rhymes, metrical jingles transmitted in folklore and mechanically repeated by children at their play, without knowledge of their signification or origin. Being in verse form they are easily understood, and traditional rhymes, or as formulas to be used in games; and, as unconscious survivals of a remote antiquity, they not infrequently serve the scientific inquirer fragments of ancient incantations for healing diseases or revealing the future, and incantations combined with sing-songs or lullabies, the intimate nature of the religious conceptions involved points back unmistakably to a mediaeval origin. Children with all their inventiveness and imagination are slaves of the letter, and most of them are keenly interested in rhyming, from generation to generation along with the games themselves. In their characteristic directness, point, and quaintness of phrase, they defy imitation, and in their faculty of arresting the imagination from age to age they reveal the instinct of perpetuity. Many of the popular rhymes are more or less among children of May games, ring-songs and dances, rounds, and kissing games which in old England were played by grown-up people, and those of the higher grades of society. And Mr Newell has proved that many of these are still current in America, have now been forgotten in the mother country, although they not infrequently have equivalents on the continent of Europe.

Under the same general head we include nursery rhymes proper, and counting-out rhymes (to decide who shall begin a game), cumulative rhymes, counting and love-games, minstrelsy, work, flower oracles, and riddle and guessing games; while on the other hand popular mottoes, old saws and maxims relating to husbandry, the weather, or the like, and all the wealth of local rhymes and sayings belong to the popular rhyme and folklore generally. The verses usually consist either of a rhyming couplet, or of four lines in which the second and fourth rhyme; they are often accompanied by a refrain, which may be a single added line, or may be made up of two lines inserted into the stanza, and in place of exact consonance, any resemblance, or similarity of sound, will answer for the rhyme.

See Folklore, Proverbs, and Riddles; also J. O. Halliwell's Nursery Rhymes of England (1842; 6th ed. 1860); K. Chambers, Popular Rhymes of Scotland (1842); E. Rolland, Rimés et Jœux de l'Enfance (Paris, 1883); and especially W. Wells Newell's admirable Games and Songs of American Children (New York, 1884), the best work of its class, and a contribution of the first importance to folklore. Appended is a list of sixty-five works bearing on the subject.

Nursing. There are few subjects affecting our social and domestic life in which more interest is taken at the present time than in the nursing of the sick, and there are not many in which time has brought about so great an improvement. Fifty years ago the nurse was almost unknown, and, consequently, the care of the sick often devolved upon persons totally unfit for, and ignorant of, the duties required of them. Now there are large numbers of refined and sympathizing women thoroughly trained in all the different branches of nursing, and it is customary for training-schools to be kept at a moment's notice. It was Miss Nightingale (q.v.) who first awakened the public mind to the need that existed for trained nurses, and who thus opened up, what has proved to be, such a large field for the employment of women taken from all classes of society. Dating from the time of her heroic services in the Crimea, the interest taken in sick-nursing has gone on steadily increasing. As a national institution Miss Nightingale opened a training-school for nurses in 1860 founded in London in connection with St Thomas's Hospital, under the title of the Nightingale Fund Training-school for Nurses. The number of probationer nurses, at first 16, had in 1871 increased to 22; and up to 1884 there were 500 positions which had been sent out from the school. The different branches of nursing are hospital nursing, private nursing, district nursing, army and navy nursing, and workhouse infirmary nursing. Monthly nursing, massage, and attendance on the insane may be regarded as special developments arising out of ordinary sick-nursing.

For those who desire to make nursing a profession, a thorough hospital training is now absolutely necessary. Hospital training may be had in two ways, either by paying a certain board for a limited time, or by entering as an uncertificated probationer to train for a certain term after training. The duties of a hospital nurse are arduous, and can only be successfully performed by those who are possessed of both bodily and mental strength as well as a strong interest in attending on the sick. Some of the work includes that of a housemaid, such as dusting the ward and cleansing the utensils. At the Glasgow Western Infirmary, for instance, the probationer is trained in the dressing of blisters, burns, sores, wounds, and in applying dressings and minor dressings; in the application of lotions, both externally and internally; in the administration of enemas; in the best method of friction to the body and extremities; in the management of helpless patients—i.e., feeding, moving, changing, their personal cleanliness, preventing and dressing bedsores; in bandaging, making bandages, padding and lining splints; in making the beds of patients, and removing sheets while the patients are in bed; in sick-cookery, such as the making of eggs, gruel, &c. The probationer has usually to wait on the doctor and attend nurses or sister as well as on the patients, and she must attend the lectures on various medical and surgical subjects that now form part of the training in most hospitals. After training as a probationer in the management of medical and surgical subjects, including both day and night work, the usual course is to become ward- or staff-nurse, or to leave the hospital for the special kind of nursing which is intended to be followed. A certificate is usually given at the close of the period of training. The age at which probationers enter the adult hospitals is from twenty-five to thirty-five, and from twenty to thirty at the children's hospitals. The salaries are usually £10 the first year, £15 the second, £20 the third. Uniform is provided in addition, and a certain amount of washing allowed for. Sisters or head-nurses receive from £200 to £250, and from £100 to £225. It is often necessary to wait for months before getting into any of the large hospitals, as there are always many more applications than vacancies. At the Edinburgh Royal Infirmary there are usually over 500 applications yearly for the 25 vacancies. The principal training-schools in London are London Hospital, St Bartholomew's, St Thomas's, Guy's, and St Mary's; in Scotland, the Edinburgh Royal Infirmary and Glasgow Western Infirmary; in Ireland, the principal hospitals are the Royal Hospital for Inebriates, and those at St Patrick Dun's, Adelaide, and Meath in Dublin, and the Royal Hospital in Belfast.
NURSING

Probationers are also trained at the Hospital for Sick Children, Great Ormond Street, W.C.; Manchester General Hospital and Dispensary for Sick Children, Pendlebury; and Royal Hospital for Sick Children, Edinburgh. Application should be made in writing to the matron of any of these hospitals. Many of the Irish hospitals, such as the Mater Misericordie in Dublin—the largest and finest hospital in Ireland—are nursed by Sisters of Mercy.

Private nursing is in some respects both more difficult and more trying than hospital nursing. The responsibility is greater as the doctor is not always at hand, and the nurse has sometimes to attend to her patient both night and day. The pay is usually from 1½ to 3 guineas per week.

Queen Victoria, taking great interest in district nursing, devoted the surplus of the Women's Jubilee Offering, amounting to £70,000, to the foundation of a systematic scheme for the training and support of district nurses, to which was given the name of Queen Victoria's Jubilee Institute for Nurses. The interest of this sum, about £2000, is to be employed in the maintenance of central institutions, where nurses are trained for this special work. There are at present four of these centres, in London, Edinburgh, Dublin, and Cardiff. Nurses who have gone through the required training at any of these Homes are eligible to be entered on the Queen Victoria Institute, Queen's House, which is entitled to wear the badge as Queen's nurse. The special teaching required, after a year of hospital work, consists of six months' approved training in a central district home, and, for country members, three months' approved training in mid-wifery. Of the scheme, started in 1887, has already made great progress, and in different divisions of the United Kingdom many branches are now working with much acceptance. This system offers a rapidly extending field of usefulness to those who wish to follow the profession of nursing, and there is an increasing demand for candidates to fill the growing number of vacancies created by the spread of the movement.

The army and navy nurses must all be ladies of good social position, and require to undergo three years' training in a general hospital. They are known as the Naval and Military Nursing Sisters, and may be ordered on active service in any war. As a reward for special service they receive the order of the Royal Red Cross. It is only of late years that trained nurses have been employed in our workhouse infirmaries, but it is now becoming quite common to find them there. There is a great demand for trained nurses to go abroad. The Royal National Pension Fund for nurses was established in 1887, and promises to be of signal service in providing for those who spend themselves in the struggle against disease and death.

Most of the British colonies follow the example of the mother-country in regard to nursing arrangements. In America the practice of nursing is very thoroughly taught in many of the hospitals, particularly those in the north-eastern states, such as the Bellevue Hospital in New York, the Long Island Hospital in Brooklyn, the Philadelphia and Pennsylvania Hospitals in Philadelphia, and the Massachusetts General Hospital in Boston. On the continent of Europe the employment of male nurses to attend male patients is common, and in the Roman Catholic countries the nursing of the hospitals is performed by the hands of Sisters of Mercy. In Germany a great impetus was given to improvements in nursing by the interest shown in the matter by the late Empress Augusta, the Empress Frederick, and the late Princess Alice of Hesse. The training of nurses on the lines adopted in Britain was instituted in Paris during 1877, by the establishment of the Ecole de Garde-malades et d'Amélie-

Wilson, Fever Nursing (Phila. 1888); E. T. Brown, Outlines for the Management of Diet (Phila. 1889); and for much useful information, Burdett's Hospital Annual.

NUT, in popular language, is the name given to all those fruits which have the seed enclosed in a bony, woody, or leathery pericarp, not opening by a natural or artificial ripening. Nut is a Latin term derived from the Greek, and means a nut, and is used as a distinctive prefix to all nut-bearing trees. The hazel-nut is an excellent example of the true nut of this order. The name nut, without distinctive prefix, is popularly given in Britain to the hazel-nut, but in many parts of Europe to the walnut. Many nuts have a considerable commercial value, from being their favourite articles of food; these are the Hazel-nut and its varieties, the Black Spanish, the Barcelona, the Smyrna, the Jerusalem filbert, and the common filbert; the Walnut, Chestnut, Hickory, and Pecan; the Sonari, the Cacao or Coker, and the Brazil or Para nut. For the Hazelnut, see HAZEL-NUT.

Nutation is a slight oscillatory movement of the earth's axis which disturbs the otherwise circular path described by the pole of the earth round that of the ecliptic, known as the 'precession of the equinoxes.' It is produced by the same causes—viz., the attraction of the sun, moon, and planets and the attraction of the last mentioned being so small as to be quite imperceptible) upon the bulging out about the earth's equator, though in this case it is the moon alone that is the effective agent. It also, for reasons which need not be given here, depends, for the most part, not upon the position of the moon in the moon's node, but of the moon's node. If there was no precession of the equinoxes, the nutation would appear as a small elliptical motion in the plane of the earth's axis performed in the same time as the moon's nodes take to complete a revolution, the axes of the ellipse being respectively 18°3 and 18°7, the longer axes being directed towards the pole of the ecliptic. But this motion, when combined with the nutation, causes the pole of the earth's axis to describe a wavy line round P, the pole of the ecliptic.

The effect of nutation, when referred to the equator and ecliptic, is to produce a periodical change in the obliquity of the ecliptic in the velocity and of retrogradation of the equinoctial points.
It thus gives rise to the distinction of 'apparent' from 'mean' right ascension and declination, the former involving and the latter being freed from the fluctuations arising from nutation.

**Nut-cracker** (*Nucifraga*), a genus of birds of the family Corvidae, with a straight, stout, conical bill, both mandibles terminating in an obtuse point, and tail nearly square at the end. Four species are known, ranging from northern Europe and Arctic Siberia to the Himalayas and China. One species (*N. carbunculus*) is occasionally seen in Britain and is not uncommon in many parts of Europe and of Asia, particularly in mountainous regions covered with pines. It is about 12 inches long. The plumage is light brown, speckled with white, except on the wings, rump, and tail, which are nearly black. The female shows a somewhat redder brown colour on the wing-feathers. The nut-cracker frequents the tops of the high pine-trees, its favourite food being the seeds of the pine cones, which it extracts, holding the cone in its foot. Its diet, however, is often very varied. Its nest is built of sticks, roots, and grass, and lined with moss or lichens, on the bough of a tree near the stem and at some distance from the ground. A closely allied species (*N. multipunctata*) is found in Cashmere, and a larger species (*N. hemispilota*), with browner plumage, in the Himalayas.

**Nut-galls.** See **Galls, Gall-fly.**

**Nut-hatch** (*Sitta*), a genus of birds of the family Sittidae, having a straight conical or prismatic bill, short stent legs, the hind-toe very strong, and large hooked claws. They run up and down trees with great agility, moving with equal ease in either direction, and without hopping, so that the motion is rather like that of a mouse than of a bird. They feed on insects, in pursuit of which they examine the crevices and remove large pieces of the bark; at other times on seeds, as those of pines, and the kernels of nuts, to obtain which they fix the nut in some crevice and then hammer it with their bill until the shell is broken, each blow being delivered with the whole strength of the body working from the hip-joint; hence the name of Nut-hatch or Nut-hack. Seventeen species are known, ranging south in the Old World to Southern India and Burma, and in the New World to Mexico, being well represented in North America. One species (*S. ceylonica*) is fairly common in many districts of England containing old timber. It occurs in the south of Scotland, and has been reported as seen in Skye and in the Shetlands; but as yet it is unknown in Ireland. It extends through central and southern Europe to Persia and even south-eastern Siberia. Its whole length is about 6½ inches. The upper parts are generally of a blue slate colour; the wing-quills grayish-tipped with white and gray; a black band runs from the base of the bill through the eye to the nape of the neck; the throat and under parts are of a pale cinnamon or rich brown colour; the legs and feet are brown. The plumage of the female is somewhat duller. Its nest is made of dry leaves or scales of cones, generally in the hole of a tree. From five to seven eggs are laid, of a white colour spotted with reddish brown. A closely allied species (*S. erithaca*), with nearly white under parts, is found in the Danish Islands and throughout northern Europe and northern Asia as far as Japan. The nut-hatch is absent from Malta and Sardinia, but in Corsica a distinct species (*S. whiteheadi*) is found, under the parts being white and the head jet-black in the male. The nut-hatches of Australia and New Guinea belong to a distinct though closely allied genus, *Sittula*. The Blue Nut-hatches (*genus Dendrophila*) are found from Ceylon and India to Burma and Malaya. The Coral-billed Nut-hatch, the only species of another genus (*Hyphoeca*), is found only in Madagascar.

**Nutmeg.** This well-known and favourite spice is the kernel—mostly consisting of the albumen—of the fruit of several species of Myristica. This genus belongs to a natural order of exogens called Myristicoceae, which contains about forty species, all tropical trees or shrubs, natives of Asia, Madagascar, and America. They generally have red juice, or a juice which becomes red on exposure to air. The leaves are alternate and without stipules. The flowers are unisexual, the perianth generally trifid, the filaments united into a column. The fruit is succulent, yet opens like a capsule by two valves. The seed is nut-like, covered with a lacinated fleshy aril, the albumen penetrated by its membranous covering. All the species are more or less aromatic in all their parts; their juice is styptic and somewhat sour; the albumen and aril contain both a fixed and an essential oil, and those of some species are used as spices. The species which furnishes the greater part of the nutmegs of commerce is *M. fragrans*; but the long nutmeg (*M. futura*), from the Banda Isles, is now not uncommon in our markets. The common nutmeg-tree is about 25 feet in height, with oblong leaves and axillary few-flowered racemes; the fruit is of the size and appearance of a roundish pear, golden yellow in colour when ripe. The fleshy part of the fruit is rather hard, and is of a peculiar consistence, resembling candied fruit; it is often preserved and eaten as a sweetmeat. Within is the nut enclosed in the curious yellowish-red aril, the *Mace* (q.v.), under which is a thin shining brown shell, slightly grooved by the pressure of the mace, and within is the kernel or nutmeg. Up to
1790 the Dutch, being the possessors of the Banda Isles, jealously prevented the nutmeg from being transplanted; but during the British occupation plants were sent to Penang, India, the West Indies, Brazil, Réunion, where they are now successfully cultivated. Nutmegs are very liable to the attack of a beetle, which is very destructive, and it is a common practice to give them a coating of lime before shipping them to Europe to kill the vitality of the germ. The nutmeg yields by expression a peculiar yellow fat, called oil of mace, because from its colour and flavour it was generally supposed to be derived from mace; and by distillation is obtained an almost colourless essential oil which has very fully the flavour of the nutmeg. Nutmegs are chiefly used as a spice, but medicinally they are stimulants and carminative. They possess narcotic properties, and in large doses produce stupefaction and delirium. Great Britain imports from 300,000 to 700,000 lb. annually, besides mace to the extent of 60,000 to 80,000 lb. The culture of nutmeg is somewhat peculiar. The plantations are always made from seed, and the plants do not produce flowers till they are eight or nine years old. The sexes being on different trees, when the plants are two years old the greater number composing a plantation are headed down and grafted with scions taken from the female tree, a few only being grafted with scions of the male to ensure fertilization. Other species of Myristica besides those already named yield nutmegs sometimes used, but of very inferior quality. The fruits of several species of Lauraceae also resemble nutmegs in their aromatic and other properties, as the catylocele of Nectandra pachyrh, the Pichurin Beans of commerce, and the fruit of Acretididioum camara, a tree of Guiana, the Camara or Ackawa nutmeg. The clove nutmegs of Madagascar arc the fruit of Agathophyllum aromaticum, and the Brazilian nutmegs of Cryptocarya moechata. All these belong to the order Lauraceae. The Calabash Nutmeg is the fruit of Monodora myristica, of the natural order Annonaceae.

Nutmeg. See Corp, Furs.

Nutrition. See the articles on Blood, Circulation, Diet, Digestion.

Nux Vomica is the name given to the seed of Strzyenos Nux Vomica. The seeds are imported from the East Indies, and are flatish and circular, about an inch in diameter, umbilicated and slightly convex on one side, externally of an ash-gray colour, thickly covered with short satiny hairs, internally translucent, tough and horny, taste intensely bitter, inodorous. The tree is a native of Coromandel, Ceylon, and other parts of the East Indies. It is a tree of moderate size, with roundish-oblong, stalked, smooth leaves, and terminal corymbs. The fruit is a globular berry, about as large as a small orange, one-celled, with a brittle shell, and several seeds lodged in a white gelatious pulp.—The bark is sometimes known as False Angostura Bark, having been confounded with Angostura Bark, which is non-poisonous, and simply has the action of a bitter. The seeds contain (in addition to inert matters, such as gum, starch, woody fibre, &c.) two alkaloids closely related to each other, which act as powerful poisons on the animal frame, and speedily occasion violent tetanic convulsions and death. These alkaloids are named Strychnine and Brucin, and exist in the seeds in combination with inactin and strychnine (or isagars) aehls. For a method of obtaining strychnine from the seeds, see the British Pharmacopœia; and for the poisons, see BRUCIN and STRYCHNINE.

Nyam-Nyama. See Niam-Niam.

Nyanga, an Arab trading station on the Upper Congo or Lualaba, at the edge of the Manyema country, in 4° 20' S. lat. From that point Stanley commenced the descent of the Lualaba in 1876.

Nyanza. See Albert Nyanza, Victoria Nyanza, Mut'a N'joe.

Nyassa, or Nyasa, the southernmost of the equatorial great lakes of East Africa, is situated about 260 miles SE. of Tanganyika and 400 inland from the east coast. It lies at an altitude of 1570 feet, is very deep in the middle, shelving rapidly from the shores, which are rocky and high. Long and narrow, it measures 360 miles from north to south and an average of 40 from east to west. The river Shiré emerges at its southern extremity, and goes south to the Zambezi. The waters of the lake are sweet and abound in edible fish. Although the Portuguese had knowledge of the existence of the lake under the name of Maravi early in the 17th century, Livingstone was the first to fix in 1859 its exact situation and to navigate it.

Nyassaland, a name applied to the regions immediately south, west, and north-west of Lake Nyassa, but without conveying any precise limitation of boundaries, practically means the region in which the African Lakes Company of Glasgow has carried on its operations since its foundation in
1878; it works hand in hand with the missionaries of the Established and the Free Church of Scotland, whose principal stations are at Blantyre, some distance to the south of the lake, and Bandalwe, half-way up its western side. Both the commercial company and the mission stations were founded for the direct purpose of interfering with the slave-dealings of the Arab marauders, and they have had much trouble owing to the hostility of these people. Nyassaland (or Nyasaland) was the nucleus of what was in 1891 constituted British Central Africa Protectorate, under an Imperial Commissioner, with an area of 500,000 sq. m. and (1896) 237 European inhabitants. Lying on the western and southern shores of Lake Nyassa, it forms the eastern portion of British Central Africa, which stretches towards the interior and the Zambesi. The western portion is mainly administered, since 1894, by the South Africa Company. In the portion more immediately under the Commissioner are thriving plantations of coffee, cinchona, sugar, and tobacco. See ZAMBESIA, and Sir H. H. Johnston's Central Africa (1897).

Nyaya. See Sanskrit Literature.

Nyborg. See Fyen.

Nyctaginaceae, a natural order, partly herbaaceous plants, both annual and perennial, and partly shrubs and trees. There are about 100 known species, mostly night flowers. Some have beautiful flowers, as those of the genus Mirabilis, known in gardens as Marvel of Peru.

Nyctalopia, the defective vision of persons who can see in a faint light but not in bright daylight; sometimes applied to the opposite defect, inability to see save in a strong daylight.

Nycteribida, very remarkable, wingless, spider-like, Dipterus insects, parasitic on bats.

Nykerk, or Nieuwkerk, a Dutch town in Gelderland, 28 miles S.E. of Amsterdam. Pop. 7599.

Nyköping, a seaport of Sweden, situated on a bay of the Baltic, 92 miles SW. of Stockholm (100 miles by rail), manufactures machinery and cotton. The castle, now ruined, ranked in point of strength next to those of Stockholm and Calmar. King Waldemar was imprisoned here after his dethronement in 1283, till his death in 1302. Eric and Waldemar, brothers of King Birger, were left in 1317 to perish of hunger in a dungeon, the keys of which the king threw into the sea. In horror of this deed the people seized the castle and demolished the town, which was taken and dismantled by the Russians. Pop. (1891) 9349.

Nyghau (Portax tragocamelus), a species of antelope, with somewhat ox-like head and body, but with long slender limbs, and of great activity and fleetness. It is one of the largest of antelopes, and is more than four feet high at the shoulder. The horns of the male are about as long as the carcases smooth, black, pointed, slightly curved forwards. The female has no horns. The neck is deep and compressed, not rounded as in most of the antelopes. A slight mane runs along the neck and part of the back, and the breast is adorned with a long hanging tuft of hair. The back is species elevated into a hump between the shoulders. The nyghau inhabits the dense forests of India and Persia, where it has long been regarded as one of the noblest kinds of game. The name is Persian, and signifies 'blue ox.' It is often taken, like other large animals, by the enclosing of a large space with nets, and by great numbers of people. It is a spirited animal, and dangerous to a rash assaulit. It is capable of domestication, but it is said to manifest an irritable and capricious temper.

Nympheas, a natural order of exogenous plants, growing in lakes, ponds, ditches, and slow rivers, where their fleshy root-stocks are prostrate in the mud at the bottom; and their large, long-stalked, heart-shaped, or peltate leaves float on the surface of the water. Their flowers also either float or are raised on their stalks a little above the water. The flowers are large, and often very beautiful and fragrant. There are usually four sepals, and numerous petals and stamens, often passing gradually into one another. The ovary is many-celled, with radiating stigmas, and very numerous ovules, and is more or less surrounded by a large flesdy disc. The seeds have a farinaceous albumen. More than fifty species are known, mostly natives of warm and temperate regions. The root-stocks of some of them are used as food, and the seeds of many. See Water-lily, Lotus, Victoria, and Euryale.—Very nearly allied to Nympheas are Nelsumbaeae. See Nelsumbo.

Nymphs, in Greek Mythology, female divinities of inferior rank. Inhabiting the sea, streams, groves, meadows and pastures, grotoes, fountains, hills, glens, and trees. Among them different classes were distinguished, particularly the Oceanides, daughters of Oceanus (nymphs of the deep ocean which flows around the earth), the Nereids, daughters of Nereus (nymphs of the inner depths of the sea, or of the Inner Sea—the Mediterranean), Potamides (River nymphs), Naiads (nympha of the fountains, lakes, brooks, wells), Oreads (Mountain nymphs), Nymphae (nympha of glens), and Dryads or Hamadryads (Forest nympha, who were believed to die with the trees in which they dwelt). They were the goddesses of the fertilising power of moisture, possessed prophetic power, and took interest in the nourishment and growth of infants, the chase, and dancing. They are among the most beautiful conceptions of the poetic fancy of the ancient Greeks. See Krause, Die Mynchen, Grazien, Horens and Nymphen (Halle, 1871).—For Nymph in natural history, see Cheysalis.
the fifteenth letter of our alphabet, is the only letter which cannot be traced to the Egyptian hieroglyphics. It is believed to have been an ideographic picture invented by the Semites to express a sound only found in Semitic languages. This supposition is supported by the correspondence of its Semitic name 'אֶיִן, which means an 'eye,' with its oldest form 𐤀, which may be regarded as the picture of an eye. The sound of 'אֶיִן was a fanatical breath, resembling the h in huge. The Greeks, who took over the Phoenician alphabet, having no corresponding sound in their language, used the symbol for the vowels e, eu, and u, which they required. In the earliest Greek inscriptions 𐤀 represents all three sounds. About 550 B.C. the symbol was differentiated, the closed form 𐤀, called omicron, or 'little o,' being appropriated for the short o, while it was opened out at the bottom, 𐤀, to represent the long 𐤀, which was called omega or 'great o.' In the Italic alphabets, which were obtained from Greece before the invention of omega, only the first of these symbols appears, whereas in the Runes, which were obtained at a somewhat later date, the vowel 产业基地 is expressed by a symbol derived from omega. In our English alphabet this letter has been more stable than any other. Its form is the same as that found on the Moabite stone, and its value agrees with its value in Greek and Latin, while it is the only English vowel which normally possesses the same sound which it has in French, German, and other modern continental languages. The sound is intermediate between a and u, and may arise out of either—i.e., it may represent an Anglo-Saxon a or u as well as an Anglo-Saxon 产业基地. In English it has three values: the name-sound heard in note, which is the original sound, the longer sound heard in not, and the neutral vowel heard in son. In English the name-sound may be represented in ten ways, as in the words pole, goat, toe, yeoman, son, see, hunt, boy, been, ove, and though.

Oahu, one of the Hawaiian Islands, north-west of Hawaii. Area, 690 sq. m. It has two parallel volcanic mountain-chains, with many inactive craters. Its valleys and plains are fertile, yielding indigo, cotton, sugar, and coffee. Containing Honolulu, the capital, it is the most important island of the group. Pop. (1900) 58,504.

Oajinca, the capital of the mountainous Oaxaca state, on the south coast of Mexico, lies in the fertile valley of the Atoyac; altitude, 5000 feet. It has a large cathedral (1729) and educational institutions, and manufactures chocolate, cotton goods, cigars, &c. Pop. (1805) 52,641.

Oak (Quercus), a genus of trees and shrubs of the natural order Cupulifera, having monoeocious flowers, the male in slender catkins or spikes, the female solitary or clustered; the fruit a nut or acorn, oblong, ovate, or globose, protruding from a woody cup formed by the enlarged scales of the involucres, the leaves are decidual or evergreen, alternate, entire, lobed, orulate. There are about 300 species, spread over nearly the whole northern hemisphere, except the extreme north. They are more numerous in America than in Europe; a few are found in Asia, none in tropical Africa, in Australia, or in South America except about the Andes. The common or English oak (Quercus robur), the most widely distributed of the species, extends all over Europe, except the extreme north, and penetrates into central Asia by way of the Caucasus. In Britain there are two well-marked 'races,' which in their more extreme forms have been designated and described by some authorities as species, while by others they are, and with better reason, regarded merely as distinct semi-natural varieties of Quercus robur.

Fig. 1.—Common Oak (Quercus robur pedunculata): a, branch in fruit; b, male flower; c, female flower.

The form that is most common—Quercus robur pedunculata—is characterised by having stalkless or nearly stalkless leaves, while the acorns are borne on more or less elongated stalks. The other form—Quercus sessilispora—has these features inverted; the leaves are stalked and the acorns stalkless. The former is found most plentifully in the south and midland counties of England, the latter in the west and north, and in Scotland. But though these peculiarities of structure and geographical distribution are more or less true and constant, the two forms are not only found growing together in all districts, but the extremes of structural difference are also linked together by individual trees which exhibit every intermediate gradation of structural disparity. The Durmast Oak (Quercus sessilispora pubescens) which is most abundant in the New Forest, Hampshire, but is also found in company with the others in various parts of the country, differs only from the stalkless fruitful variety in having the leaves more or less downy on the under side, and in retaining them longer in winter than either of the others. Prior to the introduction of iron into shipbuilding, the comparative merits of the timber of these several forms of oak were vigorously discussed in both Britain and France, but without any sound conclusion being deduced. So much is the quality of oak timber
affected by the soil and other circumstances in which the trees grow, that it is not improbable that the advocates on either side may have unwittingly confounded the wood of one variety with that of the other. The strength and durability of the timber of either kind is as unquestionable as is the extreme longevity of the trees. The timber of no other European tree combines in itself the essential elements of strength and the greatest hardness and elasticity, in the same degree as the oak. Longevity is a characteristic of all species of oak, but the British oak is celebrated above all others for the great age to which it attains. In many districts of England, and in a few about Scotland, there exist huge venerable living remains of giant oaks, whose age cannot be computed with accuracy, but which, when compared with younger trees, are certainly known to be 300 or 400 years old, may, without improbability, be reckoned to have stood for a thousand years. Many of these ancient trees are historical landmarks, being associated with the events and the names of persons of the remote past. Legendary though some of these associations may appear to be when applied to such as the 'King Oak,' in Windsor Forest, which is said to have afforded shade and shelter to William the Conqueror, it is far from improbable that the tree may have been of considerable age at the time of the Conquest. The circumference of the trunk of this tree in 1864, at 3 feet from the ground, was 26 feet. But there are many larger living oaks in other parts of the country. The Cowthorpe Oak, for instance, in the village of that name, 6 miles SE. of Knaresborough, measured, at 3 feet from the ground, 48 feet in circumference. This tree is a wretched fragment, yet lives and puts forth leaves annually. Taking the less favourable character of the climate of the West Riding of Yorkshire, when compared with that of Windsor Forest, into account along with the immensely greater bulk of the Cowthorpe Oak than the King Oak, it is not extravagant to assume that the former may be twice the age of the latter. The oak from remotest antiquity has had a celebrity among trees; it has been regarded as the 'Monarch of the Forest.' It was held sacred by the Greeks and Romans and by the ancient Gauls and Britons. The history of the use of the timber of the oak as material for shipbuilding may be said to date from the time of King Alfred (see NAVY). The timber is also employed in architecture, cabinet-making, carving, mill-work, and coopering; and the sawdust was formerly employed in the dyeing of fustian. The bark is of great value as furnishing tan for the use of the tanner. It yields a bitter extract named Quercine, which is employed in medicine as a tonic and astringent. Colouring matter is also obtained from it, which is used in dyeing wool. The acorns are excellent food for swine; and their im-

Fig. 2.—Sessile-fruitcd Oak (Quercus robur sessiliflora) Branch in Fruit.
of the best adapted trees, owing to the facility with which it stands or sends saplings up from its roots on being cut down. Cosewood oak is valuable for firewood, the making of charcoal for cooper work, and the making of crates, &c., while the bark is always marketable for the purpose of the tanner. The acorns of all species of oak supply oil in quantity, which has been used in cookery and for other domestic purposes.

Many other trees bear the name oak popularly applied. Thus, the Poison Oak (\textit{Rhus toxicodendron}), a shrub or small tree of North America, Indian Oak (\textit{Pterocarya foetida}), Afrikan Oak (\textit{Ephedra afghanica}), and Black False Oak (\textit{Lithocarpus jucundus}), which belongs to the same natural order with Quercus, are examples of the popular but erroneous use of the name oak.

\textbf{Oakham.} the county town of Rutland, in the vale of Catimose, 25 miles WNW. of Peterborough. The castle, every peer passing which must forfeit either a horseshoe or a fine, is in ruins except the hall, used for county business. The fine parish church, with a lofty spire, is restored by Swane in 1588-99 at a cost of £6100; and Aldred's and Johnson's grammar-school (1584; reconstituted 1855) has an endowment of £1200 a year. Beer, boots, and hosey are made. Pop. 3204.

\textbf{Oakland.} capital of Alameda county, California, is on the east side of San Francisco Bay, 41 miles from San Francisco. It is a beautiful town, with its streets and avenues lined with evergreens, oaks, and surrounded with gardens and vineyards. It is the terminus of the Southern Pacific Railroad, and steam ferry-boats ply constantly to San Francisco. Besides numerous churches and schools, a Congregational seminary, a large Roman Catholic college (1859), and the state homes for the adult blind, the city contains canning-factories, manufactories of cotton and woolen goods, jute, iron, nails, shoes, pottery, carriages, and agricultural implements. Pop. (1890) 48,682; (1900) 66,600.

\textbf{Oaks.} See \textit{HORSE-RACING.}

\textbf{Oakum.} a tangled mass of tarred hemp fibres, is made from old rope by untwisting the strands and dropping the fibres from each other. Its principal use is in caulking (q.v.) the seams between planks, the space round rivets, bolts, &c., for the purpose of preventing water from penetrating. The reeling of oakum is well known as an occupation for prisoners in jail.

\textbf{Oases.} (through Latin and Greek from the Coptic), fertile spots in a desert, due to the presence of water in underground supplies. The best known and most historically famous are those of the Libyan Desert and the Sahara; they occur also in the deserts of Arabia and Persia, and in the Gobi. The French have created many oases in the Algerian deserts by sinking Artesian Wells (q.v.). The formation of the oasis is due to the presence of water in the sands—especially date and palm oases—with barley, wheat, rice, and millet, when the fertile area is large enough to admit of settled occupation. In the Libyan Desert are the oasis of Siwa (where was the temple of Jupiter Ammon; see \textit{AMMON}) in the north, Erfoud, Ariat, Dakhel, and Kharghe (the oasis magnet, 120 miles W. of Thlebes). In the western Sahara Tnat, 1000 miles SW. of Tripoli, is the best known; in the eastern Sahara are Fezzan (q.v.), Gadamass (q.v.), Bilma (q.v.), and Air (q.v.) or Asben. See \textit{Desert.}

\textbf{Oates.} Titus, was born about 1650, the son of a Norwich ribbon-weaver who, from an Anabaptist preacher under Cromwell, became at the Restoration rector of All Saints', Hastings, where he was baptised on 20th November 1660. He was brought up at Oakham school, Merchant Taylors' (1665), and Eton College, Cambridge (1667) where he was admitted a sizar at St John's. Next taking orders, he held several curacies and a naval chaplaincy, but was as often expelled for infamous practices, of which perjury was not the worst. So, come forward to back up his history, the Tonge, he resolved to connect the narrative of a horrid plot, and, feigning conversion to Catholicism, was admitted as 'Brother Ambrose' to the Jesuit seminaries of Valladolid and St Omer. From both in a few months he was expelled for misconduct, but, returning to London in June 1678, he forthwith communicated to the authorities his pretended plot, the main features of which were a rising of the Catholics, a general massacre of Protestants, the burning of London, the assassination of the king, and the invasion of Ireland by a French fleet. Charles tried to use the plot to attempt; but Oates swore to the truth of it before a magistrate, Sir Edmund Berry Godfrey, who on 17th October was found dead in a ditch—murdered probably by Titus and his confederates. All London straightway went wild with fear and rage; Shaftesbury skillfully fanned the excitement, and Oates became the hero of the day. A pension of £480 was granted him, and a suite of apartments at Whitehall set apart for his use; wherever he went the mob cheered him as the 'saviour of his country.' Bedloe, Dangerfield, and other wretches came forward to back up his history, the queen herself was assailed; and many Catholics were cast into prison. Some thirty-five of them were executed, including five Jesuits and old Viscount Stafford; but after two years a reaction set in, and Oates was driven from his rooms in the palace. In May 1683 he was fined £100,000 for calling the Duke of York a traitor, and being unable to pay was imprisoned; in May 1685 he was found guilty of perjury, and sentenced to be stripped of his canonicals, pilloried, flogged, and imprisoned for life. The Revolution of 1688 set him free; and a pension was even given him of £500; but in 1696 he writes to the Secretary of State, describing his worse than utter destitution. He died 13th July 1705. See the Histories of Burnet, Echard, Lingard, and Macaulay.

\textbf{Oath.} In law, is the declaration, attested by the name of God, which is required on entering certain public offices and before giving evidence in a court of justice. Of oaths taken on entering office, the most important is the coronation oath, administered to the sovereign by an archbishop or bishop of the Church of England in presence of all the people (see \textit{CORONATION}). The oaths required before entering the privy council, and certain government offices have now been reduced to three in number— the oath of allegiance, the official oath, and the judicial oath. The oath of Allegiance (q.v.), 'to be faithful and bear true allegiance to her Majesty,' and the official oath, 'to well and truly serve her Majesty, and to be faithful and bear true allegiance to the Crown of Great Britain and Ireland.' These oaths are to be tendered. All the judges of the inferior courts, and some of the judges of the superior courts, take, in addition to the oath of allegiance, what is known as the 'judicial' oath, 'to do right to all manner of people after the laws and usages of this realm, without fear or favour, affection, or ill-will.'
OATHS

OATHS

Members of parliament now take only the oath of allegiance, which has come in the place of the several oaths of allegiance, supremacy, and abjuration formerly required from every member of both Houses of Parliament and from all persons holding office in the United Kingdom. In some particular times, oaths were required on many trivial occasions and from numerous classes of persons. By 5 and 6 Will. IV. chap. 62, and several succeeding statutes, however, nearly all these unnecessary oaths have been abolished and declarations have been substituted. For example, oaths were still taken by privy-councillors, by archbishops and bishops, by peers, baronets, and knights on their creation, by aliens on being naturalised, by recruits, and others.

The most important oaths affecting the general public are those which are administered in courts of justice to jurors and witnesses. Jurymen, who are called on to exercise their functions, whether in civil or criminal cases, are sworn to tell the truth, and to try the issue between the parties, and a true verdict to give, according to the evidence. Further, no person could give testimony upon any trial until he have in one form or another given a pledge that he will narrate the truth; he thus renders himself liable to the temporal penalties of perjury in the event of his wilfully and corruptly giving false testimony. In order to take an oath, an affirmation, or an affirmation under oath, the process is in this form: 'The evidence I shall give shall be the truth, the whole truth, and nothing but the truth, so help me God.' The universal usage in England and Ireland was for the witness, after hearing the oath repeated by the officer of court, to kiss the New Testament; but in 1892 the equally legal practice of swearing with uplifted hand came into use. There is an ordinance of the Emperor Julian prescribing that the oath be taken iuramentum sanctimoniaea. In Scotland the witness, standing and holding up his right hand, repeats the oath after the judge, as follows: 'I swear by Almighty God, and as I shall answer to God at the great day of judgment, that I will tell the truth, the whole truth, and nothing but the truth.' Children under twelve years of age are never admonished to take an oath, but only to repeat the truth. Children between twelve and fourteen may take the oath, but only if the judge is satisfied that they understood its nature. By the Act 1 and 2 Vict. chap. 103, legislative sanction has been given to the rule of the common law that all persons shall be bound and to take an oath, which is lawfully administered to them, 'provided they are administered in such form, and with such ceremonies as the parties swear declare to be binding on their consciences.' Thus, a Jew is sworn on the Penta- tuch, with his head covered; a Mohammadan, on the Koran, laying his right hand flat on the sacred book and then touching it with his forehead. A Chinaman is sworn by the ceremony of breaking a saucer before taking the oath. As regards the persons entitled to administer oaths, Lord Brougham's Act of 1851 provides that 'every court, judge, justice, officer, person, now or hereafter, having by law or by consent of parties authority to hear, receive, and examine evidence, is hereby empowered to administer an oath to all such witnesses as are called upon by statute (18 and 19 Vict. chap. 42) all diplomatic and consular agents abroad are empowered to administer oaths and do notarial acts. At the same time the old practice of persons voluntarily taking oaths before a justice of the peace—e.g. by a debtor as a further security to his creditor; and in various instances not connected with any judicial proceeding—has been put an end to by the statute 5 and 6 Will. IV. chap. 62. It is here enacted that it shall not be lawful for any justice of peace, or other person, to administer or cause to be administered any oath, affidavit, or solemn affirmation, touching any matter of which he has no jurisdiction or cognizance. To some extent it is left to the discretion of the justice whether the particular oath or affirmation be one as to which it is proper to administer an oath.

Of late years there have been made many alterations of the law as to oaths in relief of persons having conscientious scruples. Relief in this direction was first granted to Quakers, Moravians, and Separatists; but the principle of substitution, whether as witnesses or on other occasions where an oath was formerly required (see AFFIRMATION). A further concession was made in 1854 to those who, not being Quakers, yet refused to take the oath from sincere conscientious motives, such being allowed also to affirm. Previous to 1869 atheists and persons who admitted that they had no religious belief were excluded from giving evidence in courts of justice. This exclusion of the testimony of atheists was put an end to, and at the same time the principle of substituting affirmations for oaths was largely extended by the Evidence Further Amendment Act of 1869 (32 and 33 Vict. chap. 68). This statute provides, 'If any person called to give evidence in any court of justice, whether in a civil or criminal proceeding, shall object to take an oath, or shall be held incompetent to take an oath, such person shall, if the presiding judge is satisfied that the taking of an oath would have no binding effect on his conscience,' make a promise and declaration in a statutory form (sect. 4). When in 1890 Mr Bradlaugh, member for Northampton, claimed to take an affirmation under these Evidence Amendment Acts in lieu of taking the usual parliamentary oath, a select committee of the House of Commons reported that the acts did not apply to the oath taken by members of parliament. This view was confirmed in 1893 by the courts of law in the case of Clarke v. Bradlaugh, 7 Q.B.D. 38. In 1883 the government brought in a bill permitting members of parliament to affirm, but it was lost. Finally, however, in 1888, a short statute, 51 and 52 Vict. chap. 46, provides that every person upon objecting to be sworn, and stating his reasons for doing so, in the court before which he is called, shall be permitted to take an affirmation instead of an oath. The evidence thus given shall be admissible in court, and the character and effect as if he had taken the oath; and if any person making such affirmation shall wilfully, falsely, and corruptly affirm anything which, if affirmed on oath, would have amounted to perjury, he shall be liable to punishment as if he had committed perjury. Further, the Act 52 and 53 Vict. chap. 63, sect. 3, provides that in every statute passed since 1850, unless a contrary intention appears, the expressions 'oath' and 'affidavit,' in the case of persons allowed for the time being to affirm or declare instead of swearing, shall include affirmation and declaration, and the expression 'swear,' in the like case, includes affirm and declare. All the enactments relating to the administration of oaths are consolidated by the statute 52 Vict. chap. 10, known as the Commissioners for Oaths Act 1886. Affirmations in Great Britain (1889).—United States statutes permit the making of affirmation by those who object to take oaths. Some states grant further relaxations than others.

Oats (Avena), a genus of edible grasses, containing many species, a number of which are valuable for the grain which they produce, and some useful for hay. The Linnean genus Avena, as now
Oats are a variety of grasses known for their edible seeds, which are commonly used as a cereal grain. They are characterized by their jointed spikelets and narrow leaves. The species with the most commercially significant yield is Avena sativa, which is known for its high yield and adapts well to various climates. The term "oats" is derived from the Old Norse word "oatt," which is also the origin of the word "oatmeal.

Oat cultivation is extensive, with a rich historical and agricultural backdrop. In ancient times, oats were grown in regions far and wide, from Europe to Central Asia. In modern times, oats are widely grown in Europe, North America, and Asia. They are known for their ability to grow in a variety of soil types and climates, making them a versatile crop.

The oat plant is typically grown from early spring to late summer. The seed is harvested when the grain is mature, and the husk is easily removed, leaving the paler grain. Oat seeds are rich in protein, fiber, and important vitamins and minerals, making them a valuable food source.

Oats are also used as animal feed, as they are a good source of nutrients for livestock. They are often used in the diet of horses, cattle, and other farm animals.

In summary, oats are a valuable crop with a long history of cultivation. Their versatility and nutritional value make them an important part of global agriculture.
OB

is of fine quality for fodder. All these are varieties of the Common Oat, The White and Black Tarantaran, both of which have their origin in the Altaic Mountains, within the frontier of the Chinese dominions; and flows north-west and north for 2120 miles to the Caspian Sea, which is connected with the ocean. Its chief tributaries are the Irtysh, the Tchulym, Tom, and Tehlinyn, all navigable. On the banks of the Ob are Barnam, Tomsk, and Narym. At present only a few steamers ply on the great water-system of the Ob, which nevertheless seems destined to become a great commercial thoroughfare. The explorations of Professor Nordenskiöld, but more especially the tentative voyages of Captain Wiggins in 1874 and 1876, from Dundee through the Kara Sea to the Gulf of Ob, repeated in later years, have proved the feasibility of this direct route, and the accessibility of the northern basin of the Siberian river to western European commerce.

Obadiah, the shortest book in the Old Testament canon, the work of one of the twelve 'minor prophets,' of whose personality absolutely nothing is known. The name is not uncommon, meaning 'servant of Jehovah,' and was borne by the devout chamberlain of Ahaziah, King of Judah (2 Kings 8:26), who protected the prophets of the Lord from the fury of Jezebel. Delitzsch thinks the author of the prophecy may have been identical with the Obadiah mentioned in 2 Chron. xvii. 7, as one of the Levites sent by Jehoshaphat to teach the law in the cities of Judah. From internal evidence of the date of composition of the book may, with much probability, be put shortly after the capture of Jerusalem by Nebuchadnezzar, about 587 B.C. The book was placed next to Amos merely because the prophecy of doom upon Edom is an amplification of a pronouncement earlier by Amos (Amos ix. 12). This passage in Obadiah (verses 1-9) is closely parallel to Jeremiah, xlix. 7-22, from which indeed Knobel, Bleek, and Reuss think it directly borrowed. Ewald maintained that the first seven verses of Obadiah were really a prophecy of Babylon, written during the invasions of Rizan and Pekah, that the eleventh refers to the capture of Jerusalem by the Aramaeans and Philistines in the reign of Jehoram, and that the remaining verses were compiled by a later writer, partly from the older prophet (who was also used by Jeremiah), and partly from other sources. Caspari offers strong reasons for his statement that the words of Obadiah were modified and expanded by Jeremiah. Some scholars again, as Keil, have supposed unnecessarily that Joel, vii. 12, is a distinct reference to Edom. The book of Obadiah possesses high individuality of style, and contains a few peculiar words. It has ever been favourite reading among the Jews, and it was from it that they derived the name of Edom' as applied to Rome, to Christians, and all their enemies. The book consists of two well-marked divisions, of which the first (1-16) denounces destruction to Edom, and the second (17-21) prophecies the Restoration of Israel.

See the commentaries on the prophecy by Ewald, Orell, Hitzig, Keil and Delitzsch, and Pusey; the books on the Seals of Jeremias (1859), and Robertson Smith (1892), Duham (1875); also the special commentaries by Hendewerk (1836) and Caspari (Leip. 1842); Archdeacon Perowe in the 'Cambridge Bible for Schools' (1889), and Farrar's Minor Prophets (1890).

Oban, a fashionable watering-place of Argyllshire, 84 miles N.W. of Stirling, and 136 of Edinburgh, by a railway opened in 1850. It curves round a beautiful and almost unbroken coast, which, sheltered from every wind by the island of Kerrera on the west and by the high shores of the mainland, forms a spacious bay, crowded in summer by yachts and steamers. A mere 'clochán' when Dr Johnson visited it in 1772, Oban began to be feued in 1803-20, and in 1832 was considered one of the Ayr parliamentary burghs. It is now the great tourist headquarters of the West Highlands, possessing some thirty hotels and splendid steamboat facilities. Objects of interest are the picturessque ruins of C. G. Osbaldeston's oban, Stalffang Castle (see Étive), and a prehistoric cairn or dwelling, discovered in 1890. Pop. (1821) 1330; (1871) 2413; (1881) 3991; (1891) 4996.

Obé, or Obi, the name given to the magical arts or witchcraft practised by Obében-men and Obében-women among the negroes of the West Indies and the United States. It is substantially similar to the corresponding superstitions all the world over. See HAYTI, NEGROES, MAGIC, WITCHCRAFT; and H. J. Bell, Obech: Witchcraft in the West Indies (1900).

Obeld. El. capital of Kordofan, in the eastern Sudan, 220 miles S.W. of Khartoum, consists of a number of villages, originally separate and inhabited by Semitic races, but now joined into one town. Gun-nariable, ivory, gold, and ostrich-feathers are the chief articles of trade. Pop. estimated at 35,000. Near this place, in 1883, a force of Egyptians under Hicks Pasha, with an English staff, was exterminated by a large army of the Makuri.

Obelisk (Gr. obelos, obeliskos, 'a spit'), a word applied to four-sided monuments of stone and other materials, terminating with a pyramidal pointed top. These monuments were placed upon bases before gateways of the principal temples in Egypt, one on each side of the door. They served in Egyptian art for the same purposes as the stelae of the Greeks and columns of the Romans, and appear to have been erected to record the honours or triumphs of the monarch. They have four faces, are cut out of one piece, and are broader at the base than at the top, at a short distance from which the sides form the corners of a pyramid in which the obelisk terminates. They were placed upon a cubical base of the same material, which slightly surpassed the breadth of their base. Each side of the obelisk at the base measures 3/4 of the height of the shaft; from the base line to that where the cap or pyramidion commences. The cap is also 3/4 of the same height. Their sides are slightly concave, to increase their apparent height. Their height varies from upwards of 100 feet to a few inches. The sides are generally sculptured with hieroglyphs and representations, according to their respective titles, and they are usually in one line of deeply-cut hieroglyphs down each side. Hewn in the rough out of a solid piece in the quarries, they were transported down the Nile during the inundation, on rafts, to the spot where they were intended to be erected, and there raised to their horizontal position by inclined planes, aided by machinery. Some obelisks, before their erection, had their pyramid capped with bronze gilded, or gold, the marks of such covering still being evident on their surfaces. The use of obelisks is as old as the appearance of art itself in Egypt; these grand, simple, and geometric forms being used in the 4th dynasty, and continued till the time of the Itonians. Their object is enveloped in great obscurity. At the time of the 18th dynasty it appears that religious ceremonies and oblations
were offered to the obelisks, which were treated as divinities. Their sepulchral use is evinced by their discovery in the tombs of the 4th dynasty, and the vignettes of early papyri. The most of them date from the 18th and 19th dynasties. Two which formerly stood at Heliopolis (q.v.) were re-erected by Nannees II. at Alexandria, and have been

Cleopatra’s Needle, Thames Embankment, London.

popularly known as Cleopatra’s Needle. One, which long lay prostrate, was, after an adventurous voyage, brought to London in 1878, and erected on the Thames Embankment; it weighs 186 tons, and is 63½ feet high. The other, presented by the Khedive to the United States, was set up in Central Park, New York, in 1881. There are several large ones in Rome (that now at St Peter’s having been taken to Rome by Caligula), one in Florence, one in Paris (given by Mehemet Ali in 1837), and Leipsius’s in Berlin (the oldest and smallest of all, 2 feet 1½ inch high), besides many others that have found their way into European museums. By far the largest obelisk in the world is the Washington monument (1885), at Washington, D.C. It is of marble, 55 feet square at the base, and 555 feet high.

See Zoëga, De Origine et Usu Obeliscorum (1797); Bich, Notes upon Obelisks (1823); Gouringa, Egyptian Obelisks (1885).

Ober-Ammergan, a village in the valley of the Ammer in Upper Bavaria, 45 miles SW. of Munich, with 1400 inhabitants. Here the famous Miracle Play is performed every ten years. See MYSTERIES AND MIRACLE-PLAYS.

Oberland, Bernese. See Bern.

Oberlin, Johann Friedrich, a pastor distinguished for his active benevolence and usefulness, was born at Strasburg, 31st August 1740, and in 1767 became Protestant pastor of Waldbach, in the Ban de la Roche or Stenthal, a wild mountainous district of Alsace. Here he spent the remainder of his life, combining an affectionate diligence in the ordinary duties of the pastorate with wise and earnest endeavours to promote the education and general prosperity of the people.

The district had suffered terribly in the Thirty Years’ War, and the scanty population which remained was sunk in poverty and ignorance. Oberlin introduced better methods of cultivating the soil, and various branches of manufacture, and made roads and bridges. He founded an itinerant library, began the first infant schools, and introduced ordinary schools in the district. Pastor Oberlin was latterly consulted in all that concerned the temporal and spiritual welfare of the people. The population, which was scarcely 500 when he entered on his labours, had increased to 3000 at the close of the century. The district still continues prosperous, and the population in 1890 was 6000. Oberlin was ably assisted in his reformatory labours by his pious housekeeper, Louise Scheppler, who survived her master eleven years. He died 1st June 1829. Notwithstanding the humble sphere in which his days were spent, his name as a philanthropist has extended over the world, and his example has stimulated and guided many. The Royal Agricultural Society of France bestowed a gold medal upon him in 1818. A collected edition of his writings appeared at Stuttgart (4 vols. 1843).

Obermann. See SÉNANCOUR.

Oberon, the king of the elves or fairies, and the husband of Titania. The name is derived from the French Auberon or Alberon, and that from the German Alberich (q.v. ‘elf’ and rich). Oberon is first mentioned as ‘Rois du royanne de la fée’ in the 13th-century French poem of Huon de Bordeaux. The quarrel between Oberon and Titania and their subsequent reconciliation through Huon, a French noble, and Amanda, daughter of the sultan of Babylon, whom the former leads home by the help of Oberon, after many difficulties, form the basis of this tale, which was afterwards shaped into a popular prose romance. The name first appeared in English in Lord Berners’ translation (Early Eng. Text Soc. 1883), and was adopted in many ballads, and also in Green’s play, The Scottish History of James IV., slain at Flodden. Neither these, however, nor Spenser’s use made the name familiar, but Shakespeare’s Midsummer Night’s Dream, where, as Keithley points out, the fairies mythology was attempted to blend the elves of the village with the fae of romance. The fairies here agree with the former in their diminutive stature, in their fondness for dancing, their love of cleanliness, and their child-like abstracting propensities. Like the fays, they form a community ruled over by the princely Oberon and the fair Titania. Wieland used the subject for his well-known romantic poem, and Planché’s adaptation of this forms the subject of Weber’s opera. The old chanson de geste was edited by Guissard and Grandmaison (Paris, 1869). See Liebrecht’s German translation of Dunlop’s History of European Fiction (1851).

Obesity, or Corpulence, may be defined to be ‘an accumulation of fat under the integuments or in the abdomen, or in both situations, to such an amount as to embarrass the several voluntary functions.’ A certain degree of fatness is not only quite compatible with health, but, as has been shown by Glisson and Eberle, it is of considerable use in the animal body, partly in consequence of its physical and partly in consequence of its chemical properties; and it is only when the fatness begins to interfere with the discharge of any of the vital powers that it can be regarded as a morbid condition. Obesity may occur at any period of life, but it is most commonly after
the fortieth year that the tendency to an inordinate accumulation of fat begins to show itself. After that time, in the case of men the pleases of the table are usually more attractive than in earlier life; and the efficiency of leads to an extended diet, while in women the cessation of the power of child-bearing induces changes which tend remarkably to the deposition of fat. The extent to which fat may accumulate in the human body is enormous. Daniel Lambert (1769–1808) weighed 730 lb. at the age of twenty, and was still extant in 1808; according to the investigations of the late Dr Hutchinson (the inventor of the spirometer), the normal weight of a man 6 feet high should not exceed 178 lb. Dr Elliottson has recorded the case of a female child, a year old, who weighed 60 lb.

The predisposing causes of obesity are a peculiar habit of body, hereditarily transmitted; inactivity; sedentary occupations, &c.; while the more immediate or exciting causes are a rich diet, including fatty matters, and matters convertible in the body into fats, such as saccharine and starchy foods, and the partaking of such a diet to a greater extent than is necessary for balancing the daily waste of the tissues. 'Fat meats, butter, oily vegetable substances, milk, saccharine and farinaceous substances are the most fattening articles of diet. The brown stairs and the warm baths, indulgence, and living upon saccharine and farinaceous articles, upon dates, the nuts from which palm-oil is obtained, and upon various oily seeds are the means usually employed to produce this effect' (Copland's Dictionary). The knowledge of the means of inducing obesity affords us the best clue to the rational treatment of this affection. It is a popular belief that the administration of acids—vinaegar, for example, or one of the mineral acids—will check the deposition of fat; but if the desired effect is produced it is only at the cost of serious injury to the vital, bone, muscular and urinary organs. The employment of soap and alkalis, as advocated a century ago by Flennying, is less objectionable than that of acids, but the prolonged use even of these is usually prejudicial. The question of obesity affords us the most ample opportunity of illustrating the general action of some of our commonest substances. Sea-wreck (Focus seawrack) is this affection has also been strongly advocated. It is prescribed in the form of an extract, and its value is probably dependent on the isofine contained in it.

A very interesting Letter on Corpulence, published in 1863 by Mr. William Banting (1797–1878), in which he records the effect of diet in his own case, after medical treatment had failed, is well worthy of the attention of those who are suffering from the affection of which this article treats. The following are the leading points in his narrative. He is only 5 feet 6 inches in stature (and therefore, according to Dr Hutchinson's calculations, ought to have weighed about 142 lb.), and in August 1862 weighed 292 lb. 'Few men,' he observes, 'have led a more active life . . . so that my corpulence and fatness (and the consequent negative of necessary bodily activity, nor from excessive eating, drinking, or self-indulgence of any kind, except that I partook of the simple aliments of bread, milk, butter, beer, sugar, and potatoes, more freely than usual, and more unusually, I could not stoop to the use of shoe, nor attend to the little offices humanity requires without considerable pain and difficulty; I have been compelled to go downstairs slowly backwards, to save the jar of increased weight upon the ankle and knee joints, and been obliged to puff and blow with every slight exertion.

By the advice of a medical friend he adopted the following plan of diet: 'For breakfast I take four or five ounces of beef, mutton, kidneys, broiled fish, bacon, or cold meat of any kind except pork; a large cup of tea (without milk or sugar), a little biscuit, or one ounce of dry toast. For dinner, five or six ounces of any fish except salmon, any meat except pork, or any sweet wines, as well as bread, an ounce of dry toast, fruit out of a pudding, any kind of poultry or game, and two or three glasses of good claret, sherry, or Madeira: champagne, port, or beer forbidden. For tea, two or three ounces of fruit, a rusk or two, and a cup of tea without milk or sugar. For supper, three or four ounces of meat or fish, similar to dinner, with a glass or two of claret' (p. 18). '1 breakfast between eight and nine o'clock, dine between one and two, take my slight tea meal between five and six, and lay up nine' (p. 80). Under this treatment he lost in little more than a year (between the 26th of August 1862 and the 12th of September 1863) 46 lb. of his bodily weight, while his girth round the waist was reduced by inches. He reported himself as restored to health, as able to walk up and down stairs, and play with his children, and to enjoy freedom; and safely to leave off knee-bandages, which he had necessarily worn for twenty years past. He made his own case widely known by the circulation of his pamphlet (which has passed through several editions), and 'numerous reports have been sent with the pamphlet, and the whole show that 'the system is a great success'; and that it is so we do not doubt, for it is based on sound physiological principles. Other more or less similar systems have since been recommended; one, with two successful cases, is recorded in the Edinburgh Medical Journal for December 1880. Such a radical change of diet, however, should not be adopted without medical advice, as in some cases it might cause disturbance of digestion or excretion, and lead to new dangers to health.' See (under Fast) Fasting (Vol. IV., p. 359), Training.

Obi. See Ob, and Ong.

Object, and its correlative, Subject, are terms used in a perplexing multiplicity of senses, the same author, philosophical or semi-philosophical, being frequently in a different sense and in a different meaning attached to him by the writer. Thus it may be said that while ordinarily the subject is the knowing mind, the object is that which is known, thought, felt, seen, imagined—the psychological corresponding fairly with the grammatical usage. At another time the subject is the ego, while the object is the non-ego, the external world, with an implication that the objective has a firmer, surer ground, if not wholly independent of the subjective, then at least less liable to vary or fluctuate. On the other hand, if the non-subject, the subject, is the truly real, the phenomenon is independent of the knowing mind. Yet again, that which is the law of the consciousness, which is prior to experience, is by some regarded as more indefeasible and objective than the fleeting elements of conscious experience. For some, objective is that which is common to all minds (and the non-subjective) at all times, and the subjective that which is peculiar to my mind or any given mind at any given time. Thus the essence of the subjective becomes the most objective thing in existence; really objective truth is that which from the nature of the case is prior to and independent of experience. It is needless to point out that, when the subject (or self) is the subject, the subject may be said to become its own object. In general, however, that is objective which deals
nuch with the external world, and that subjective
which is mainly based on introspection of mental

states.

In addition to the possibility of confusion arising
out of current usage, it should be remembered that
in the middle ages, and even in Descartes and
Spinoza, subject nearly meant the same as sub-
stance (something highly real); and in William of
Ockham objective is that which the moral feigned,
the image or representative idea as opposed to
the real object which exists independently. Object
used as 'end,' 'aim,' 'purpose' (with the object of
doing so and so') is a barbarous but irrepro-
sable abuse. Colonel
is by no means the only
writer who fails to make himself clear about the
distinction between 'omni-jective' and 'sum-
jective,' as Carlyle represents him.

Oblates (Lat. oblatus, oblast, 'offered up'),
the name of a class of religious bodies in the Roman
Catholic Church, which differ from the religious
orders strictly so called in not being bound by
the solemn vows of the religious profession. The insti-
tute of oblates was one of the many reforms
introduced in the diocese of Milan by St Charles
Borromeo, towards the close of the 16th century.
The members consisted of secular priests who lived
in community, and were merely bound by a promise
to the bishop to devote their time to any service
which he should consider desirable for the interest
of religion. St Charles made use of their services
chiefly in the wild and inaccessible Alpine districts
of his diocese. The oblates of Mary Immaculate,
founded at Marseilles in 1815, have nine houses in
France, and are numerous in
Canada, British India, and the United States.
Two Irish reformatory
are under their charge.

Obligation, Days of, holidays on which faith-
ful Catholics are bound to abstain from servile
work and to hear mass. These are, for England
and Wales, Circumcision, Epiphany, Ascension
Day, Corpus Christi, SS. Peter and Paul, Assump-
tion, All Saints, Christmas Day. Scotland adds
to these St Andrew, and Ireland St Patrick and
the Annunciation.

Oboe, a French possession on the
African coast of the Red Sea, inside Bah-el-
Mandeb, and opposite Perim. Area, 2300
sq. m. (1800) 570,000.

Oboe (Fr. hautbois; Ger. hoboé, hoch-
holz), a treble reed musical instrument, to
which the bassoon may be said to be the base.
Its reed is double, like that of the
bassoon and the chanter of the bagpipe,
and consists of two thin blades of cane
attached by silk thread to a short metal
tube. A similar instrument may be traced
from the earliest times from Egyptian and
Greek sculpture and paintings; and the
Kensington Museum contains many speci-
mens from Arabia, China, India, Wal-
lia, and Persia. The modern instrument, how-
ever (shown in the figure), from successive
improvements and additions bears little
resemblance to its ancient prototype, and
is one of the most complicated and intri-
gate of wind-instruments. It is made vari-
able in length, according to the variety
of notes desired, necessitating many keys
for the higher notes. It is an octave instrument like the
flute (q.v.), and its usual compass is from
C below the stave to F in alt., although
several semitones higher can be produced.

For orchestral purposes it is pitched in the key of
C, but in military bands a Bb instrument is some-
times used, and its music is written in the G clef.

The tone of the oboe is rich, and, from its
great power in swelling and diminishing the sound, it
is capable of very various expression. The
oboe has the privilege of giving the pitch to the
violin in the orchestra. Beethoven, Mozart, Bach,
and nearly all the great composers make extensive
use of the oboe in their compositions. The oboe
d'Amore and the Oboe di Caccia, oboes of the
class of A and E respectively, are nearly obsolete.

Oboc is also the name of a treble stop on the
organ, its bass being the bassoon. See 'Oboe,' in
Grove's Dictionary.

Obolus (Gr. obolos or obeles, 'a spit;' see
Numismatics, p. 550), the smallest of the four
common Greek coins and weights, the sixth part
of the Drachma.

O'Brien, William Smith, Irish patriot, was
born 17th October 1803. Descended from
the royal line of Thomond, to which belonged
the great king, Brian Boru, he was the second son
of Sir Edward O'Brien, Bart., of Dromoland,
County Clare, in favour of whose eldest son the
ancient barony of Inishquin was revived in 1822.
He was educated at Harrow and Trinity College,
Cambridge, and entered parliament for the pocket
borough of Ennis in 1826. Though a Protestant,
he supported the Catholic claims; and for some
years he gave an independent support to the
Tory party. He lost his seat in 1835, but was
returned for the county of Limerick in 1835, and from
that time till 1843 generally supported the Whigs.
But he gradually gave up hope of getting justice
for Ireland from the imperial parliament, and on
the 20th October 1843 he announced his
adhesion to O'Connell's Repeal Association. But O'Connell's
movement to bring on an appeal to physical force soon
made a wide gulf in sympathy between his party
and those fiery spirits who became known as 'Young
Ireland,' and whose fervid and warlike poetry and
praise filled the columns of the Nation newspaper.
To this party O'Brien soon joined himself, and the
more force policy, by means of which O'Connell
had gained so many triumphs, was now abandoned
by the group of young and eager enthusiasts.
The death of Thomas Davis in September 1845 removed
many of their leaders, and left the Association
without the leadership of O'Brien. His honour
and patriotism are undoubtedly, not so its practical
wisdom; and his ardent temperament and the sight
of the sufferings of his country soon hurried him
on to dangerous courses, and brought him into
collision with the law. Still his views were much
more moderate and sensible than those of some of
the zealots of his party. The sentence of John
Mitchell for treason-felony in the spring of 1847
hastened the projected rising, which, however,
proved a miserable fiasco, ending ludicrously in
an almost bloodless battle in a cabbage-garden at
Ballingarry, in County Tipperary. Smith O'Brien
was arrested, tried by a special commission at
Thurles, and sentenced to death; but the sentence
was commuted to transportation for life. In May
1854 he was released on condition of not returning
to Ireland, and in 1856 he received a free pardon.
He spent his remaining years in private life, partly
at Bangor in North Wales, and died there, 16th
June 1864. See A. M. Sullivan's New Ireland
(1867), and Sir G. Duffy's Young Ireland (1880).

Obscene Prints, Books, or Pictures
exhibited in public render the exhibitor liable
to be indicted for a misdemeanour. Persons
exposing them in streets, roads, or public places
are also liable to be punished as rogues and vag-
abonds with hard labour. An important change in
the law was effected by Lord Campbell's Act, which was passed in 1867, to suppress the traffic in obscene books, pictures, prints, and other articles. Any two justices of the peace, or any person authorized by them, may search for and seize such books, &c., and carry them before the magistrate or justices, who, after giving due notice to the occupier of the house, and being satisfied as to the nature and object of keeping the articles, cause them to be destroyed.

**Obscurantists.** ("lovers of darkness"); Lat. *obscurare, 'to darken"). the name given to those who are supposed to look with dislike and apprehension on the progress of knowledge, especially to such as defend theological prejudices against what is believed to be scientific truth.

**Observatories.** See **Franciscans.**

**Observatory,** an institution supplied with instruments for the regular observation of natural phenomena, whether heavenly or terrestrial, or more especially of those phenomena which are subject to measurement or calculation. In some observatories all three classes of observation are carried on, but in most cases special attention is paid to astronomy alone, and only such meteorological observations are taken as are required for the calculation of the effects of atmospheric phenomena upon the position of a heavenly body; there are, however, several observatories which are devoted solely to meteorological or magnetic observations.

The most important work which is carried out in public astronomical observatories is the determination of the movements of the sun, moon, and planets among the stars; and, as a corollary to this, the relative positions of the stars to which the other heavenly bodies are referred. In early times the Greek astronomers fixed these positions by means of the Arca
dy Sphere (q.v.) and the Astrolabe (q.v.). Ptolemy made use of a Quadrant (q.v.); and many centuries after Tycho Brahe converted this form of instrument into an Altazimuth (q.v.), with which he made a long series of observations of the altitudes and azimuths of the heavenly bodies. King Christian of Denmark erected for him; and he also measured with great exactitude their angular distances from each other by means of a Sextant (q.v.). It was not till the middle of the 18th century that the improvement of the clock by Graham enabled astronomers to rely on it for the determination of right ascensions by the times of passage across the meridian by means of a quadrant. A pair of such instruments pointing respectively north and south were erected at the Royal Observatory, Greenwich, by Bradley; and his successors from 1790 till they were displaced, are still used for determining the Right Ascension of Stars (q.v.). At the same time the accuracy of readings was greatly increased by the invention of the micrometer-microscope, which made it possible to measure spaces to the thousandth of an inch. It is now possible to determine far greater parts of the heavenly circle, however, could be relied upon for accurate motion in the plane of the meridian, but Römer remedied this defect by inventing a separate instrument, the Transit (q.v.). With the transit and quadrant Bradley commenced that series of observations of the positions of the sun, moon, and planets, and of stars for reference, which has been continued ever since at Greenwich, and on which, in combination with less extensive series at Paris and Königsberg, all our tables of the motions of the heavenly bodies are founded. In modern observatories the transit and mural circle are combined into one instrument, the Transit-circle (q.v.). An important auxiliary to the transit-circle is the Revolver (q.v.), and a barygraph, an instrument by which, in various forms, is now found in all well-equipped observatories, the principle in all cases being the same—viz., the registration on a revolving cylinder of paper of the times of transit across the system of spider-like lines in particular districts, as well as of number of the sidereal clock, by means of electric currents, which pass through electro-magnets when the circuit is closed either by the observer or the clock, thus causing a momentary attraction of a piece of soft iron, and producing a corresponding mark on the paper either with pen or a steel point. This system, while improving somewhat the accuracy of the individual observations, admits of a large number being made at intervals of two or three seconds, and leaves the observer free to make several observations of zenith distance during the passage of a star across the field of view. The observations of stars at the observatories of Greenwich, Paris, Washington, and Oxford are mainly directed to the most accurate determination of the places of a limited number, and the deduction of their proper motions by the comparison of their positions observed at widely-spread intervals by Bradley, Piazzi, and Groombridge; at other observatories differential or zone observations of large numbers of stars have been made, with the object of making a complete and tolerably accurate survey of the heavens.

A large number of observatories, chiefly in Germany and America, are devoted to a very different class of observations—viz. differential observations with the Equatorial (q.v.) of comets and small planets as referred to comparison-stars, and the search for such objects; whilst at other observatories, among which that of Pulkova may be mentioned, the measurement of double stars with the micrometer is laid down as the chief object. Of late years two new subjects have been introduced in the routine of observational work—photography and spectroscopy. The former was carried on quite many years at Keble Observatory under Sir Me De La Ruc's auspices, and at his private observatory at Cranford, and the work is now being continued at many observatories, both public and private; the latter has been taken up at a number of Italian observatories, and particularly in the observatories of Rome, Bologna, and Seccili, and it now forms part of the regular system at Greenwich; whilst the observatories at Paris, Berlin, and Vienna are equipped for these physical observations, and in America and Australia they are vigorously carried on at several observatories—Nebulon, in particular, being provided with a four-foot equatorial reflector for this purpose, as well as for the examination of nebulae.

The most important work of an observatory, however, consists not in making observations which are easily multiplied, but in reducing and publishing them—viz., the reduction of the observations into their proper parts, and remaining for higher qualifications. However various may be the observations, the mathematical method of eliminating their errors is the same in all cases; and it is when such treatment is required in any inquiry that it should be undertaken at a public observatory, where this rigorous method will be applied.

In addition to regular astronomical observations of all kinds, national observatories are usually charged with the distribution of time signals, and the testing of chronometers for the navy—matters of great practical importance, especially in Great Britain, where Greenwich time is communicated directly by telegraph to more than 600 towns.

There were observatories amongst ancient
Babylonians and Egyptians. Of modern observatories that at Cassel dates from 1501, Tycho Brahe's at Uraniborg from 1576; that of Greenwich (q.v.) was founded in 1675. The oldest in the United States is the Lick Observatory, Harvard College, erected in 1830; now there are upwards of sixty in the United States, in which forty are located on Mount Blanc, at a height of 14,470 feet.

OBSIDIAN, a natural glass—the vitreous condition of an acid lava. It is hard and brittle, with remarkably vitreous lustre, and perfectly conchoidal fracture, the edges of the fractures very sharp and cutting like glass. It varies from semi-transparency to translucency only on the edges. It is often black or very dark gray; sometimes green, red, brown, striped, or spotted; and sometimes chatoyant or aventurine. Some obsidians are rendered porphyritic with microscopic crystals of sandstone; others are often highly vesicular and plentifully charged with spherical vesicles usually arranged in the line of lava-flow. The rock is usually rich in crystallites and microlites (the 'beginnings of crystallisation'), which are frequently arranged in parallel or undulating lines = 'fission-structure.' Stones of this vapour-phase of the obsidians in size abundantly in the obsidians. Obsidian is thus a kind of lava. It is capable of being polished, but it is apt to break in the process. It is made into boxes, buttons, ear-drops, and other ornamental articles; and before the uses of the metals were well known it was employed in different parts of the world, for making arrow and spear heads, knives, &c. It is found in Iceland, the Lipari Islands, Vesuvius, Sardinia, Hungary, Spain, Teneriffe, Mexico, South America, Madagascar, Siberia, &c. Black obsidian was used by the ancients for making this, and this was brought to Rome from Ethiopia. It was used for the same purpose in Peru and Mexico. Mirrors of black obsidian are indeed still employed by artists. Chatoyant or aventurine obsidian is very beautiful when cut and polished, and ornaments made of it are sold at a comparatively high price.

OBSTETRICS (Lat. obstetricia; 'a midwife,' from obsto, 'I stand before,' thus literally 'a woman who stands before'; the other adjective is obstetrical; and also Midwifery (A.S. mid, 'together with,' and wif, 'a woman'). As a branch of medical science and practice obstetrics is concerned with the study and care of women during the processes of pregnancy, parturition, and the puerperium, or lying-in. As a department of medical study it embraces the anatomy and physiology of the female organs of generation, the phenomena of conception and pregnancy, of labour, normal and abnormal, and of the puerperium and the return of the organs to their non-pregnant condition. Strictly speaking, these processes of generation and physical and psychical development naturally are conditions little or no skilled help or assistance. But, while theoretically this may be so, it is still the case that these processes each produce an effect on the female organism which results in great modifications of the ordinary vital functions, so that the condition is one of continued physiological tension, which at any moment may pass into a pathological or abnormal condition in which skilled assistance is of the utmost importance. There can further be no doubt that the influence of work in states of civilisation tend greatly to increase the dangers of the reproductive process, so that the members of highly civilised communities are peculiarly liable to disaster; but at the same time the rudest savages are by no means free from these risks, and the care which most of them take of their women during pregnancy and parturition amply proves how conscious they are of this fact (but see COUVADE). The dangers with which the reproductive process is associated may be in some measure realised when it is understood that during pregnancy women are liable to be affected by many of the ordinary diseases in an aggravated state, while the expulsion of the ovum—abortion—a process in itself attended by grave dangers; that during parturition the child may present some part of the body other than the head, causing increased difficulty, often impossibility of spontaneous delivery; that there may be such a disproportion in the size of the child's head and the pelvis, due to disease or deformity; that from disease or exhaustion the uterus may be incapable of expelling its contents; that after the birth of the child the natural processes for checking haemorrhage from the site of the placenta may be at fault, or again the retention of a blood-clot or fragments of placenta may expose the patient to the risks of septicaemia or blood-poisoning. These are but a tithe of the dangers which surround the reproductive process, but they give an ample explanation of the existence of a science and practice of obstetrics, and other similar dangers may be obviated. With regard to parturition itself it may be noted that the great majority of labours (95 per cent.) are natural—that is, the head presents, and they are spontaneously accomplished within twenty-four hours. But in civilised countries, and under the best practice, it is estimated that one in 190 women dies within a fortnight after labour. It would be out of place in a work of this kind to enter into the details of this science, but a sketch of the history of its origin and development may be of interest.

Until the beginning of the 17th century the practice of obstetrics was mainly empirical. It was founded on experience and superstition, and was in great measure destitute of an anatomical or physiological foundation. Such practice is seen in the present day among uncivilised races, and we find procedures described as employed by the Egyptians, Jews, Greeks, and Romans in vogue among the North American Indians and negroes at the present time. During the empirical period we find, as we might expect, that the ordinary practice was wholly in the hands of women. At first female midwives were employed for the offices they could, but soon a distinct class of midwives arose, whose experiences or special aptitude fitted them for the duty. All ordinary labours were attended by them, and they did not yield up a difficult case to the surgeon or physician until they had exhausted a code of practice partly reasonable as founded on experience, partly superstitious, but often very elaborate. When these resources failed, the aid of the male practitioner, who combined the offices of priest and physician, was usually invoked. At first the aid yielded by these was largely in incantations, prayers, and invocations, and invocation of special deities. Elithia in among the Greeks and Lucina among the Romans were the chief deities presiding over childbirth, though among the Romans particularly a number of minor deities were regarded as specially available for special complications. With the growth of medical knowledge the purely religious office of the priest became detached from that of the physician, and among the Egyptians in quite early times the physician became a separate functionary and rendered much more accurate and scientific information. The importance of the organs involved greatly limited their practice, and cases of difficult or delayed labour were usually treated by Caesarean section, or later by some form of embryotomy. See CESAREAN OPERATION.

The writings of Hippocrates (400 B.C.) contain
of Salerno about the beginning of the 16th century. Some time previously this school had inaugurated the study of anatomy, and the light shed thereby had its influence on the dark and degraded practice of obstetrics. Progress was, however, slow, and its practice continued to be chiefly reserved for the hands of women, to whom clung the superstition of the dark ages. Yet in the hands of anatomists like Vesalius, Fallopius, Berengarius, and surgeons such as Paré, a scientific basis was again being laid, and the knowledge of Soranus and Moschion being rediscovered. And, while the all ordinary labours were managed by women, the surgeons were called in to assist when a difficulty arose. By them turning was rediscovered, and embryotomy, Cesarean section, &c. were restored and developed on more scientific principles. By-and-by, especially in France, the practice of obstetrics by surgeons gradually gained ground, though there, and still more elsewhere, its practice by men lay under a reproach. The invention of the obstetric forceps by the Chamberlens, about the beginning of the 17th century, gave a great impulse to Anglo-Saxon medicine. Dr. Moschion published his Treatise, which ran through seven editions, and was for long the standard work on the subject. It was translated into English by Hugh Chamberlen in 1672, and it seems to be about this time that men began generally to engage in the practice of obstetrics. In France, the practice of lying-in was still an art. In 1663, and others took it up in England, whilst La Vallière, the mistress of Louis XIV., by employing Julian Clement, a surgeon of high eminence, in her first confinement in 1663, did much to establish the practice in France.

Since the revival of the study of anatomy and physiology the progress of scientific obstetrics has been steady and sure. The reproach under which its practice so long lay has been entirely removed, and the colleges of physicians, which at one time refused their fellowships to any one engaged in obstetric practice, now receive candidates in the same terms as other physicians, and all medical licensing bodies demand an adequate knowledge of its theory and practice from every candidate for their diplomas. The science and practice have been built up by a host of workers, the mere mention of whose names would extend this account of what it may be of use to indicate some of the great advances and discoveries on which the art rests.

(1) The Rediscovery of Podiatric Version or Turning.—In 1530 Paré described this operation, whose value had been recognised and its method described by the 1st century B.C. However, it was not until 1672 that it was lost to practice since the 7th century. Paré showed how it could be performed, and pointed out its advantages in saving fetal life; and it is certain that many children were delivered safely by means of scissors being employed at the time. One of the earliest cases recorded was that of a child born in 1747 in the town of Forfar, by Dr. James Simpson, in the hospital for the poor.
certainly marks one of the most beneficent advances in the history of obstetrics—probably the greatest advancement of the foregone. Besides relieving and abolishing untold suffering in ordinary labour, it permits the performance of many operations and the correction of untoward conditions which previously were impossible or irremediable. It should be added that Hypnotism (q.v.) has within recent years been employed on the Continent for the same purpose.

(4) The Employment of Antiseptics and the Prevention of Puerperal Fever.—Till 1870 the great scourge of maternity hospitals, and also a frequent cause of disaster in private practice, was the prevalence of outbreaks of puerperal fever or septicamia. In that year the teaching of Lister began to influence obstetric practice, and since then rigorous antiseptics are the rule in all maternity hospitals. Thus a mortality reaching in many instances to 6 per cent. of all cases has been reduced almost to zero, and this improvement of obstetric practice has been removed.

The teaching of midwifery is provided for in the curricula of all the medical schools of the United Kingdom. In most a three months' course of lectures with attendance on a certain number of practical cases which students must undertake. The Scottish universities require attendance on a six months' course of 100 lectures, besides practical training by the bedside. As has been said, the licensing bodies demand an adequate knowledge of midwifery from every candidate for a license to practice; and further, at every maternity hospital the training of nurses by lectures and demonstration is regularly carried on. The ignorant midwife of the past is thus being replaced by trained women, who are competent to undertake the management of all cases of obstetric importance. There is, however, considerable room for improvement in the training and certification of these midwives. In recent years, in Great Britain and elsewhere, the facilities offered to women to obtain a full medical training are being greatly increased, and it is not unlikely that in course of time a very large part of the practice in this department, at the present undertaken by men, may be transferred to women. And that properly educated women are capable of undertaking all the responsibilities of this department of practice is shown by such cases as those of Moshèmâ Boivin and Leachpile, who (in the words of Velpeau), 'although the pupils of Baudeloque, were not afraid to shake off, to a certain extent, the yoke of his scientific authority, and whose high position and dignity form the starting-point of a new era for the science of obstetrics in Paris.'

See amongst English works on the subject those of Playfair and Barnes; American, those of Lusk and Parvin, and the American System of Obstetrics; the French treatise by Tarnier and Budin; and German works by Schroeder, Spiegelloe, and Winckel (all of which have been translated). See also articles in this work on Abortion, Cesarean Operation, Fetus, Forces, Prenancy, &c.

Ocarina, a recent Italian toy-instrument of flute-like sound, made of pottery, and shaped like the body of a bird (without head or neck).

Ocean, William of. See Occultation.

Occasionalism. See Descartes.

Ocleve, Thomas. See Oiticica.

Occlusion, a term applied to the solution of a gas by a melted solid—as of oxygen by melted silver—which gas is given up by the melted metal, and so, if the composition of silver the metal sometimes 'spits' or gives off the gas in bubbles, whereby roughening its otherwise smooth surface. Sometimes the gas is absorbed or 'occluded' (in a wider sense) even though the metal be not fused—e.g. hydrogen gas by cold palladium, carbonic oxide by red-hot cast-iron.

Occultations (Lat. occultus, 'a concealment') are neither more nor less than 'eclipses'; but the latter term is confined by usage to the obscurcation of the sun by the moon, and of the moon by the earth's shadow, while the former is restricted to the eclipses of stars or planets by the moon. Occultations are phenomena of frequent occurrence; they are confined to a belt of the heavens about 10° 17' wide, situated parallel to and on both sides of the equinoctial, and extending to equal distances north and south of it, being the belt within which the moon's orbit lies. These phenomena serve as data for the measurement of the moon's parallax; and they are also occasionally employed in the calculation of longitudes.

Occultism. See Magic, Alchemy, Astrology, Theosophy.

Oceana, generally the body of salt water that separates continent from continent, embracing altogether about three-fifths of the whole surface of the earth. The separate oceans are the Atlantic, separating Europe, Asia, Africa, and America in the Pacific, between America and Asia; the Indian, lying south of Asia, and limited on the east and west by Australia and South Africa; the Arctic, surrounding the north pole; and the Antarctic, surrounding the south pole. There are articles on the several oceans, and the physical features and characteristics of the ocean will be found described under Sea.

Oceania, a name sometimes given to the fifth division of the globe, comprising all the islands which intervene between the south-eastern shores of the continent of Asia and the western shores of America. It naturally divides itself into three great sections—the Malay Archipelago, Australasia, or Melanesia, and Polynesia (q.v.).

Ocelot (Felis pardalis) is a species, with several varieties, which is confined to the New World, and ranges from Arkansas in the north to Patagonia. These animals are inhabitants of forests, and very expert in climbing trees. Their prey consists in great part of birds. They are beautifully marked and coloured. The coloration varies considerably, but the ground tint is always a rich red or tawny colour, blending finely with the dark brown on the margins of the open spots, of which there are chains along the side; the head, neck, and legs being also variously spotted or barred with dark brown and black.

Ochil Hills, a pastoral range occupying parts of the Scottish counties of Stirling, Firth, and Clackmannan, and extending from the vicinity of Stirling north-east to the Firth of Tay. It is 24 miles in length, and about 12 in breadth. Chief summits are Benleigh (2963 feet), Dunyveg (1375), and King's Seat (211). The hills, which are formed chiefly of greenstone and basalt, contain silver, copper, and iron ores. See Beveridge's Between the Ochils and the Forth (1888).
O'Connell, Bernardino, Italian reformer, was born at Siena in 1487, and joined the Franciscan Observants, but in 1534 changed to the Capuchin order, of which he became superiors general in 1545. He was vicar-general of the order, having already before joining it gained the reputation of a man of great piety and eloquence. In 1542 he was summoned to Rome to answer to the Inquisition for certain evangelical tendencies which had been noticed among his followers. As the Venetian ambassador had been three years before, and had been much talked about. Warned by Cardinal Contarini, Ochino turned back at Bologna and fled to Geneva, where Calvin gave him a welcoming hand. In December 1545 he was appointed preacher to the Italian congregation in Augsburg, but fourteen months later was driven from the city by the advent of the imperial troops. From this time Ochino was dogged by misfortunes, and was never able to stay long in any one place. He first found refuge in England, invited there by Cranmer; he was made pastor to the Italian exiles and given a prebend in Canterbury Cathedral. In England he wrote the Tragedy, a series of dramatic dialogues translated from the original Latin into English by Bishop Ponet, which is believed to have had some influence on Milton's Disputation of Divorce (1643). In 1553 Ochino fled to Switzerland, and ministered to the Italian exiles in Zurich for ten years. Then the publication of Thirty Dialogues, one of which the Calvinists stated to contain a defence of polygamy, occasioned his being banished precipitately from the city. In the dialogue in question Ochino states expressly and repeatedly that 'polygamy is immoral'; but, being a man of inquiring, questioning intellect, he at the same time threw out the suggestion that there might be individual cases in which it might perhaps be permissible the individual. He accordingly in some certain he had God's approval. Ochino fled to Poland, but was soon driven thence by an edict directed against all foreigners, and died in flight at Schlacken in Moravia in the end of 1584. See Life by Berath (Eng. trans. by Helen Zimmerm, 1876).

Ochres are native pigments consisting of clays or earths composed chiefly of silica and alumina, along with oxide of iron or more rarely with other oxides. Some are found in a natural state fine enough to be used after being simply washed. The two important classes of ochres are the yellow and the red, the former containing hydrated oxide of iron, the hydrated oxide of iron, and that of the latter the red or sesquioxide. Umbre (q.v.), which is classed with the ochres, contains manganese as well as oxide of iron. Yellow ochres are reddened by being burned. Most of the ochres can be prepared artificially, but these are not so safe for artists purposes as the native earths. The latter are remarkable for their stability, as can be seen in many pictures by the old masters. Yellow ochre and Roman ochre are much used both by artists and for general purposes. Ochres, also (but the first more by artists) are the red ochres, known as light red, Indian red, and Venetian red. This last, however, is an artificial product, and, although it is an oxide of iron colour, it contains no earthy base, so that correctly speaking it is not an ochre. Ochre is to be seen in the rocks of the Veneto and North Italy. About 12,000 tons are raised in some years, the value of which is roundly £2 per ton. It occurs in many other countries, there being large deposits of it in Canada. In the manufacture of gunpowder wet and dry, some of the less common metallic compounds found native are called ochres by mineralogists. Among these there are bismuth ochre, anthimony ochre, nickel ochre, and chrome ochre.

Ochterlony, Sir David, British general, was born of Scotch (Forfarshire) descent, at Boston, Massachussets, on 12th February 1758, went out to India as a cadet in 1776, and was made a lieutenant-colonel in 1803. In the following year he defended Delhi against Holkar; but his greatest services were rendered against the Goorkhas. In 1814 he stormed their hill-forts one after the other, and compelled them to sue for peace; on the renewal of the war in 1816 he sallied out against the capital chief in the hill-fort of Malam, forced it to surrender, and penetrated to within a few miles of the Nepalese capital. Peace was again made; and the treaty has remained in force down to the present time. Ochterlony was made (1816) a baronet for his success. He rendered excellent service in the Punjab and Malharrta wars of 1817 and 1818. He died at Meerut, 15th July 1825.

Ockham (more usually in the Latinised form Occam), William of, surnamed Doctor Singularis et Invictabilis, a famous 14th-century schoolman, was born in England, at Ockham in Surrey, but when in his twenty-seventh year, he went to Paris, where he was made a doctor in theology in 1270 or 1280. He entered the Franciscan order, and studied at Oxford and Paris, being a pupil, afterwards the rival, of Duns Scotus. It seems not to be correct that he took part in the contest between Philip the Fair of France and Boniface VIII, the latter of whom compiled the Tractatus Ecclesiæ . . . commissæ, usually attributed to him, having been probably written by another. But in the revolt of the Franciscans against Pope John XXII at Pernegia in 1322 he did take part, being one of the most active in the movement. After four months' imprisonment at Avignon he was repaired to Munich, and found there a defender in the Emperor Louis of Bavaria, whom he in his turn defended stoutly against the temporal pretensions of the pope. In 1342 he seems to have become general of the Franciscans. Besides insisting on the independent divine right of temporal rulers, and so in some measure clearing the way for modern constitutional ideas, Ockham won greater fame as the reviver of Nominalism (q.v.), for which he won a final victory over the rival Realism, chiefly by setting forth its real meaning in plain and simple language. He returned to Paris and Munich in 1349. His views on civil government are expounded in Super Potestate Summi Pontificis et Quaestionum Decisiones (1339-42) and Tractatus de Jurisdictione Imperatoris in Caussi Mortuopotentibus, his epochal work of 1347, and also in his Summa de Asto (1488) and the commentary on the Sentences of Peter the Lombard, and his theological in this last and the Tractatus de Sacramentis Altarum (1516). See T. M. Lindsay in Brit. Quart. Review (1872).

Ockley, Simon (1678-1729), Orientalist, was educated at Oxford, and in 1711 became Arabic professor. His History of the Saracens (2 vols. 1708-18; long a standard, though not based on the best authorities) was partly written in a debtor's prison.

O'Connell, Daniel, 'the Liberator,' greatest of Irish patriots and orators, was born near Cahirciveen in County Kerry, August 6, 1775. He was the eldest son of Morgan O'Connell, brother of the childless Maurice O'Connell, then head of an old Catholic family, who was chiefly attached to the Congregational Abbey. He was early adopted by his uncle, at whose house most of his boyhood was spent. He was placed, together with his brother, in January 1791 at the college of St Omer, the president of which, Dr Stapylton, foresaw his unusual promise. In August 1792 he was sent to the college of Douai, which was suppressed at the end of the year, and it was not without danger that the boys made their escape by Calais to England. To the end of his life O'Connell never forgot his glimpse of dominant
O'CONNELL

revolution. He entered at Lincoln's Inn in 1794, worked hard, and was called to the Irish bar in May 1798. He was soon drawn, like most eager young Irishmen, into political agitation, and it appears probable that he had some connection with the conspiracy of 1798, the unhappy issue of which cured him for life of all love for secret societies. At the same time some scandals at election trials, the degraded condition of his co-religionists, and the shameful circumstances attending the Union already shaped for him the politics of his life. The average professional earnings of his first four years were only £180, but thereafter these rapidly rose, and by the end of his career Mary O'Connell, who bore him five sons and three daughters, and with whom he lived till her death in 1836 in uninterrupted happiness. He joined the Munster circuit, and went on it for twenty-two years. He soon became famous as a counsel, as well as an unrivalled cross-examiner of Irish witnesses, and ere long was plunged in an enormous practice, amidst which he yet contrived to find time for the convivialities of that day and for a large measure of political agitation. The wide popularity of the Catholic cause, and the rare talent among his Irish admirers—was due to his fearlessness and professional dexterity, his boisterous wit and good-humour, his constant tact and readiness in reply, and not less to the violent language he often employed in court, which he defended in later days as a necessary means to awaken the slumbering spirit and self-respect of Catholics. Their hopes, which had been raised by the pledges given at the Union, soon sank low, and O'Connell now flung himself into the agitation for their rights, quickly distanced Keogh and other timid leaders of the Catholic cause at the beginning of 1811 stood out as its virtual chief.

Grattan's motion in favour of emancipation was carried in March 1813, but his bill was lost in committee. The 'securities' it proposed were most distasteful to the Catholic bishops, and O'Connell, even as an unconverted supporter of them in their policy in opposition to Grattan. The timid counsels of the pope, then a pensioned prisoner of Napoleon, were displeasing to the Catholic party, but it was O'Connell's own conscientious convictions that nothing short of repeal would be permanently satisfactory that made him free and absolutely against all compromise. His attacks on the 'iegarchal corporation' of Dublin, then an Orange stronghold, brought him a challenge from Mr J. N. D'Estere, and in the duel that ensued his pistol unfortunately inflicted a fatal wound on his antagonist, February 1, 1815. O'Connell was filled with lifelong remorse; he settled a pension on the widow, and never till his latest day passed the dead man's house without uncovering his head and breathing a prayer. At the same time he registered a solemn vow never to go out again. His career brought him into the contact of his lifetime many challenges, but only once did he allow himself to accept another—from Peel in the September of 1815. The duel was only prevented by his being arrested on his wife's information and bade over to keep the peace. Meantime the Catholic cause languished; Grattan died in 1820, and Plunket took up his mantle, but again the Lords threw out the bill. The visit of George IV. to Ireland in August 1821 raised hopes only to be dipped in the mud, while famine and commercial insecurity paralysed the public confidence. In 1823, however, a new era was opened on a broad and popular basis the Catholic Association, and before the end of the year had brought the priests into it. At first they showed much disinclination to join in the agitation, preferring the old policy of 'dignified silence'; but once they entered heartily into it, the movement became for the first time really national and irresistible. The Association was a gigantic system of organisation, perfectly new to Ireland, and aroused the greatest enthusiasm from sea to sea. By the 'Catholic Rent' a large sum of money was raised for its purposes, a penny a month not being too much. The agitation and the measures at election trials had, in 1824, it had grown to a formidable power, the average weekly rent for its last three months being as much as £600. The government in alarm brought in a bill to suppress the Association, but it dissolved itself, 13, 1825. The Irish forty-shilling freeholders now began to return to their land at the elections. Waterford was carried in 1826, and O'Connell himself stood for Clare in 1828, and was carried amid enormous enthusiasm, yet perfect order. The Clare election set the whole country afire; the lord-lieutenant, Lord Anglesey, foreboded insurrection, and even the iron Duke was appalled at the prospect; but O'Connell saw that an outbreak would ruin the Catholic cause on the very eve of its triumph, and with magical effect ended the agitation. In 1829 the Repeal movement passed at last, admitting Catholics to parliament, repealing one of their great injuries, the abjuration, and modifying that of supremacy, the 'securities' being the abolition of the forty-shilling franchise and raising the qualification to £10. On the 15th May 1829 O'Connell came to take his seat, and was heard at the bar by his right of the old oaths. He spoke calmly and admirably, but the House refused his claim by 190 to 46. He went down to Clare like a conqueror, was returned unopposed, and took his seat at the beginning of 1830, then fifty-five years old. At the new election on the King's death which was returned for Waterford.

Much of the good effect of 1829 was lost by the unnecessary insult to a sensitive people of not allowing its champion to take its seat without re-election, still more by the fact that no Catholics were appointed to the bench, and by the placing in the hands of the lord-lieutenant the power to suppress arbitrary by proclamation any assembly that seemed to him dangerous. O'Connell now formed a new society for Repeal, 'The Friends of Ireland of all Religious Persuasions,' which was quickly suppressed, only to be revived as often as the government tried to suppress it. He spoke of his other unparalysed names and forms so as to elude the letter of the law. He denounced the ministry of Wellington and Peel, and tried in 1830 to embarrass them by an unjustifiable letter recommending a run upon gold. In the face of the threatened prosecution against him in 1831 he temporised and so saved himself. In the same year he became King's Counsel, the honour having been kept back as long as possible. It was at this period that he declined the challenge of Hardinge, the chief-secretary. Liberal in every part of his imperial policy, he sought in 1831 to detach the Whigs, as later he advocated free trade in corn, negro emancipation, the removal of the disabilities of the Jews, the cause of Poland, not to speak of universal suffrage, and the drastic reformation of the House of Lords. In the autumn of 1830 the cabinet crisis had been very poor, but an independence was the result in Ireland. Under O'Connell's advice the people declined to pay tithes, and that winter disorder was rampant everywhere.

He had sat fast for Ferry, when at the general election of 1832 he was returned for Dublin. At this time O'Connell was returned, while three of his sons and two of his sons-in-law composed his 'household brigade.' Of the 105 Irish members but 23 were Tories; while of the 82 Liberals as many as 45—his famous 'tail'—were declared Repealers. The severest of all
The Repeal movement was a significant political campaign in Ireland during the 1820s and 1830s, advocating for the repeal of the Act of Union, which had united Ireland with Great Britain. The movement was led by Charles Gavan Duffy and other Irishmen, who sought to restore Ireland's parliament and assert greater autonomy and self-government.

The movement faced numerous challenges, including opposition from British authorities, and it was met with violence on occasion. The Whig party, led by Sir Robert Peel, was responsible for the introduction of the Act of Union, and the Repeal movement often found itself at odds with Peel's government.

The movement's leaders, such as Daniel O'Connell and Daniel O'Connell, Jr., were portrayed as leaders who were fighting for the rights of the Irish people. They organized meetings, rallies, and other forms of public demonstration to raise awareness and garner support for their cause.

The Repeal movement was ultimately unsuccessful, as it failed to secure the repeal of the Act of Union. However, it left a lasting legacy in Irish politics and culture, inspiring future generations to fight for Irish independence and self-determination.

The Repeal movement was a significant chapter in Irish history, and its leaders and supporters remain celebrated as heroes of the Irish struggle for independence.
O'CONNELL

of which seceded from the Association after angry disputes in 1846. Next followed the potato famine. Distraction at the sufferings of his country, dismay at the startling shadow of famine, vexation at the breach in his party, consciousness of failure in the dearest project of his life, reaction from liberties exacted in the course of his youth, the progress of insidious disease, and last of all a crazy passion for a young English girl, now combined to break down his herculean frame. He left Ireland for the last time on 20th January 1847, made a touching but scarce audible speech on the House of Commons on February 5, next went to Hastings, and from thence to Folkestone, and as he felt the hand of death upon him was filled with a great longing to reach Rome. Boulogne, Paris, Moulins, Lyons, Marseille, and Genoa were the slow stages of the journey. At the last, after some days of delirium, he died, May 15, 1847. His heart by his own desire was carried to Rome, and buried in the church of St Agatha; his body rests in the Glasnevin Cemetery, Dublin, in a crypt at the base of an Irish round tower, 163 feet high.

Daniel O'Connell was framed by nature for the part he had to play in life. Almost six feet high, of burly figure, giant strength, inexhaustible energy, and enormous powers of work, he had a splendid command of nervous language, and a mighty voice that rose high above the uproar of the crowd. A magnificent orator, a master of great and small, self-possession and rapidity of utterance. With all his exaggeration, readily in unsteadied and effective retort, richly endowed with a coarse but genuine humour, and ever thoroughly Irish, he controlled at will the wildest emotions of an Irish mob, and passed with the ease of a master from the animation and outbursts of the pavement to the tenderest pathos. He was master of all the artillery of vituperation, but it should be remembered in his defence that he was assailed all his life, the constant victim of a malignity and hatred now difficult to realise. Even the Times newspaper signified itself as an unredeemed and unredeemable sounder, and asked, like Cicero of another Catiline, 'How long shall such a wretch be tolerated among civilised men?' Yet O'Connell was no demagogue in the unworthy sense of that word, no socialist or advocate of strikes—he opposed the poor laws, the coach and six, the sunning, and rejected the proffered alliance of the Chartists, constantly denounced rebellion, and was unswerving in personal loyalty to the sovereign. He was no mere tool of Rome, and never abused Protestants as such, but advocated a large tolerance in religion far beyond the ideas of either his antagonists or his supporters, making for his aim a really Liberal Catholicism that earned the unstinted approbation of Montalembert and Lakanne. His church policy was carried out far beyond his dreams in 1869, his futility of tenure granted by the Land Bill of 1870, and indeed the majority of the Irish members in the imperial parliament has since his time adopted to heal the distresses of Ireland but shows how sound was his statesmanship and how real were the evils that he denounced. Yet together with all this good there was mixed much evil also. He was coarse, scurrilous, cunning, violent, bombastic, inimitable, more than Celtic in his looseness of phrase and exaggeration, he often played upon unworthy passions, and left behind him an inheritance of antagonism between classes in Ireland that has done much to degrade and embitter the tone of our literature. But there are Lives by his son that taught his country to manage within constitutional limits the whole machinery of political agitation, and again aroused within her the spirit of nationality and the instinct of freedom. He said himself with justifiable pride, it was the jar by the cradle of his country, and followed her

OCTOBER

O'Connell's published writings the most characteristic is the Letter to the Earl of Shrewsbury (1842). His Memoir of Ireland, Nature and Saxon (1843), never saw its second volume, and is poor and inaccurate. There is no adequate biography, though there are Lives by his son John O'Connell (1846), William Fagan (1847–48), M. F. Cusack (1872), and a short Centenary Life by the Rev. John O'Rourke (1875). See W. J. O'Connell's Personal Reminiscences and Experiences during a Parliamentary Career from 1833 to 1858 (2 vols. 1849); W. E. H. Lecky's Leaders of Public Opinion in Ireland, unquestionably the abiest estimate of his character (new ed. 1871); M. F. Cusack's Speeches and Public Letters of the Liberator (2 vols. 1874); Shaw Leveque's Peel and O'Connell (1887); the excellent study by J. A. Hamilton in the 'Statesmen' series (1888); and W. J. Fitzpatrick's authoritative and invaluable Correspondence of Daniel O'Connell, the Liberator (2 vols. 1888). The delightful letters to his wife and Archishop M'Hale, contained in the last, gave a new revelation into his character. O'Connell's articles in the National Advocate by J. Ball in Macmillan's Magazine for July 1873, and Mr Gladstone in the Nineteenth Century for January 1889.

O'CONNOR, FEARGUS EDWARD, Chartist, was born in 1794, and was educated at Parnallington and Trinity College, Dublin. He was called to the Irish bar, and entered parliament for Cork in 1825. At first a supporter of O'Connell, he became estranged from his leader, and devoted himself to the cause of the working-classes in England. His great stature and strength, his eloquence and enthusiasm, gave him vast popularity as a leader, and by his paper, the National Advocate, he has a much greater influence and a more lasting influence for Chartism. Elected for Nottingham in 1847, he presented the monster petition in the April of the following year. In 1852 he was found to be hopelessly insane, and in 1855 he died.

Oconto, capital of Oconto county, Wisconsin, on Green Bay, at the mouth of the Oconto River, 200 miles N. of Milwaukee. It has large sawmills and exporting pine lumber. Pop. (1880) 4717; (1900) 5064.

Octave (Lat. octo, 'eighth'), in the church calendar, is the eighth day after a festival, counting in the festival day itself; also, the week after a church festival.—In Music octave is the interval between a musical note and its counterpart in the concord, which is double its pitch, and occupies the position of the eighth note from it on the diatonic scale. The name octave is often given to the eighth note itself as well as to the interval.

Octavia, the sister of the Roman emperor Augustus, and wife of Mark Antony, distinguished for her beauty, her noble virtues, and the matchless interest of her vicissitudes. After the death of her first husband, Marcellus, she consented in 40 B.C. to marry Antony, to make secure the reconciliation between him and her brother; but in a few years Antony forsook her for Cleopatra. In 32 B.C. war, long inevitable, broke out between Antony and Octavia; and the conquerors divided his insurmountable debt. In the bill of divorce. But no injury was too great to be forgiven by this patient Griselda of the ancient world; and after her husband's death she brought up with maternal care not only her own children by Antony, but also those of Cleopatra. She died in 34 B.C.

Ocavian. See Augustus.

October (Lat. octo, 'eighth') was the eighth month of the so-called year of Romulus, but became the tenth when Numa changed the commencement
of the year to the first of January, though it retained its original name, notwithstanding the attempts made by the Roman senate, and the emperors Commodus and Domitian, who substituted for a time the terms Fanstius, Invictus, Domitianus. Many Roman and Greek festivals fell to be celebrated in this month, the most remarkable of which was the sacrifice at Rome of the Octobri horse to the god Mars.

**Octopus**, a widely distributed genus of eight-armed cuttle-fishes, the members of which (e.g. *O. vulgaris* in Europe, and *O. borealis* in America) usually live near shore, lurking among the rocks, preying upon crustaceans and molluscs. The term is often extended to related genera, such as Eledone, and to other members of the sub-order Octopoda. These differ in many ways from the Decapoda, such as Sepia and Loligo; thus, the suckers on the eight arms are sessile and without a horny ring; the body is more rounded, and there is no internal residue of a shell. Of the half-hundred species some are large; thus, *O. vulgaris* may have tentacles about 8 feet long, and *O. punctatus* of the Pacific coast even twice as much. These are dwarfed, however, by the gigantic ten-armed Architeuthis, of which one specimen exhibited in America had a head and body 93 feet long and arms of 30 feet, while another had a body twice as big.

Many fanciful descriptions have been given of the Octopus, notably by Victor Hugo in his *Twisters of the Sea*, in which the characters of cephalopod and polyp are dramatically combined. Large specimens may of course act powerfully on the defenses, but by nature they are timid, lurking animals, the crong cel and other voracious fishes being their most formidable foes. They are sometimes caught in sunken pots, into which they creep, and the flesh is used both as food and bait. The predominant colour is reddish, but it changes rapidly with that of the surroundings and with the temper of the animal, which has also the peculiar ability of changing the water by a discharge of inkly fluid. The eggs are enclosed in small transparent cases, and hundreds are attached to a common stalk which is glued to the rock, and protected and kept free of small newweeds, &c., by the female. For their general structure, see *Cephalopoda, Calamary, and Cuttle-fish*.

**Octroi** (Lat. *auctoritas*, 'authority'), a term which originally meant any ordinance authorised by the sovereign, and thence came to be restrictively applied to a toll or tax in kind levied from a very early period in France and other countries of northern Europe on articles of food which passed the barrier or entrance of a town. The octroi was abolished in France at the Revolution, but in 1788 it was re-established. The octroi officers are entitled to small carriages and individuals entering the gates of a town. Similar taxes are raised in Italy and elsewhere.

**Od**, the name given by Baron Reichenbach (q.v.) to a peculiar physical force which he thought he had discovered, intermediate between electricity, magnetism, and heat, but precisely with splendid success by many English poets. The Greek *œ̇δ* was simply a chant or poem arranged to be sung to an instrumental accompaniment, and all the variations of form that occurred were merely subjective, incapable of imitation, and conditioned only by the exigencies of the music. Aristeas seems to be the first to expand the simple distich into an *epode*; Aleman, to adopt the more complex form of the *carmen* or *œ̇δ*. Sappho, Alcaeus, and Anacreon carried it further, and shaped the lighter form of *œ̇δ* known to us, through the masterpieces of their greatest imitator, the Horatian. Stereichoros modified the *œ̇δ* of Aleman by elaborating a triple movement, in which the metrical wave moving in the *strope* was answered by the counter-wave moving in the *antistrophe*, the whole distich being by the *epode*, a blend consisting of a distich of each of the two. Simonides adapted this elaborate form to Dorian music, and next followed Pindar, the greatest master of the *œ̇δ*. His *Parthenia* or *œ̇δ*es for virgins, his *Skolion* or dithyrambic *œ̇δ*es in praise of Dionysus, and his encomiastic *œ̇δ*es have all perished; only his *Epigistles*, with triumphal odyssees, remain. These display an infinite variety of metrical ingenuity; no two *œ̇δ*es have the same metrical structure, yet each obeys a definite structural law, and license there is none in its irregularity. The Humanist poets imitated the simpler Eolian measures as they found them in Catullus and Horace; but many of our poets, taking Pindaric as synonymous with irregular, produced so-called *œ̇δ*es whose only likeness to their great original was their 'unshackled numbers.' But irregularity in verse is not allowable except in cases where it is a natural and peculiar element by the poetic mood in its moment of exaltation; for the most constant charm of poetry is the inevitability of cadence, which must never be lightly flung away unless to subserve another and still higher law—that of emotional necessity. It is in the hands of a master that the *œ̇δ* may safely be imitated in English; by all others the apparent artifice of the form and the necessary spontaneity of the impulse may not be reconciled.

Ben Jonson's *œ̇δ*es are unequal; Herrick's, poor; Spenser's *Epithalamium*, or marriage *œ̇δ*, is one of the most splendid triumphs of English poetry; and
Milton, in his magnificent poem, *On the Morning of Christ's Nativity*, found in this a form adequate for that poetic exaltation which was his habitual mode for Cowley's praise. Greatly an expert in the Horatian ode, when he fell in with Pindar, and imitated him, in externals at least, in a number of elaborate compositions, usually redeemed from dullness by bursts of undoubted poetic power. Dryden has left it for the Horatian imitator, and the Horatian odes, *To Miss Anne More*, *To Mrs. Alexander Welby*, and *Alexander's Feast*; and Congreve wrote not only a few admirable, if formal, examples, but an excellent critical *Discourse on the Pindaric Ode* (1705). The matchless Orinda, Lord Orrery, and Horace Walpole, followed their kind; and Gray, first drawn to this form by Gilbert West, translator of Pindar, produced in 1754 and 1756 his two inimitable Pindaric odes, the *Progress of Poverty* and *The Bard*. The exquisitely poetic, though not Pindaric, odes of Collins were given to the world somewhat earlier. Wordsworth, Coleridge, Shelley, Keats, and Tennyson poured some of their noblest verse into this form, while modifying it further, whether as regular—i.e. following a definite arrangement in stanzas, or as irregular, following no such arrangement. This is a finer ode than any poem in our language than Coleridge's *odes To the Departing Year and To France*; Wordsworth's *To Duty and Immortality from Recollections of Early Childhood*; Shelley's *To the West Wind, To a Skylark, To Liberty, and To Napoleon*, Keats's *odes To a Nightingale, On a Grasmere Urn, and To Autumn*; Tennyson's *funeral ode On the Death of the Duke of Wellington*; and Swinburne's *To Victor Hugo in Exile*.

See *English Odes* (1841), admirably selected by Edmund W. Gosse, with an excellent introduction; and the sublime and usual *English Odes* by Genevieve Whyte, in vol. xii. (1885) of the *Encyclopædia Britannica*.

**Odense**, the chief town of the Danish island of Funen (q.v.). Its cathedral was founded in 1086; and diets were held here in 1527 and 1539. Pop. (1880) 29,804; (1890) 30,277.

**Odewald**, a mountainous system partly in Baden and partly in Hesse (qq.v.).

**Oder** (Lat. *Vindras*, Slov. *Vjodor*), one of the principal rivers of Germany, rises in the Oderberg on the tableland of Moravia, 500 feet above the level of the sea, traverses Prussian Silesia, Brandenburg, and Pomerania, then empties itself into the Stettiner Haff, whence it passes into the Baltic by the three arms of the Haffnitz, Penee, and Swine, which enclose the islands of Wollin and Usedom. It has a course north-west and north of 550 miles, and a basin of 50,000 sq. m. The rapid flow, induced by its very considerable fall, together with the sitting at the embouchures of the numerous tributaries, renders the navigation difficult; great expense and labour being, moreover, necessary to keep the embankments in order, and prevent the overflowing of the river. Canals connect the Oder with the Spree, the Havel, and the Elbe; the Warthe is the only tributary of importance for navigation. On the banks of the Oder are Ratibor (where it is navigable for barges), Brezlaw, Breslau, Frankfort-on-the-Oder, Stettin, and Swinemünde.

**Odencalh.** See *Innocent XI*.

**Odessa**, in point of population the fourth city of Russia, stands on the shore of the Black Sea, about 25 miles from the estuary of the Dnieper, and 381 miles from Kief. The city is built facing the sea on a low cliff, seaward with deep ravines and hollowed out by galleries in the soft rock, in which numbers of the poorest inhabitants herd together. Above ground its streets are long, straight, and right-angled. Odessa was only founded in 1794, near a Turkish fort that fell into Russian hands in 1789; but it quickly became the principal export town for the extensive corn-growing districts of South Russia. Its growth was greatly aided by its being declared, in 1871, free for trade, and again by the construction of the railway to Kieff in 1866. The population has increased rapidly, from 1350 in 1796 to 25,000 in 1814, 100,000 in 1850, 184,800 in 1853, 270,600 in 1857, and 404,651 in 1867. Close upon 70,000 of these were Jews, and their number was increased by the admission of many of the other nationalities. The harbour is made up of a roadstead and three basins, protected by mole-structures against the dangerous winds that sweep the Black Sea. It is impeded by ice—carré-early closed by it—during an average of only a fortnight, at most. The importers in 1894 had a value of over £9,000,000 (less than in 1886 or 1891); the exports, over £21,000,000 (more than in any preceding year). The bulk of the exports is grain, especially wheat; but the figures for wheat fluctuate greatly, according to the crop years, and many of them represent the massiveness of the gross imports has steadily increased, doubling between 1886, when the figure was £27,290,000, and 1889, when it reached £10,757,700. Sugar (£1,217,400 in 1889), wool, and flour are the remaining chief items of export. The chief imports (raw cotton, oils, groceries, iron and steel, coal, food-stuffs, fruits, tea, tobacco, machinery) average £3,856,500 (five years from 1885). An average of 1295 vessels of 1,750,250 tons enter the port every year, an average of 716 of these vessels, with a combined tonnage of 1,800,000, being Russian; the import being one-fifth of this. But the Russians carry on a large and increasing coasting trade. The chief branches of industrial activity are flour-milling, sugar and oil refining, and, in a secondary degree, the manufacture of tobacco, machinery, leather, soap, chemicals, &c. Odessa has a university (1865) with close upon 600 students, and the usual cabinets and collections; a great number of schools, including a cadet, a commercial, and two music schools; several learned societies, and a public library (1829) of 40,000 volumes, now, as in the time of Potemkin, one of the best in the world. The Historical and Antiquarian Society contains treasures from the coasts of the Black Sea, belonging to the Hellenic, the Venetian-Genoese, and the Tartar-Mongol civilisations. Amongst the public buildings of Odessa we mention the cathedral (1822-48), which is the church of the Archbishop of Kiéff, three dozen other churches, a very fine opera-house (1887), palatial grain-warehouses, corn-elevators, and the *palais royal*, which, with its gardens and park, is a favourite place of resort. Monuments to Count Worontzow (1853), the Duke de Richelieu (1827)—both great benefactors of Odessa—and Pushkin (1839) adorn the city. Water is brought by aqueduct (27 miles long) from the Dniester. Numerous coast batteries have been built since 1876 to prevent a recurrence of bombardment, such as happened in the Burma war. To the value of the city in April 1854, Odessa has an undeniable minuteness as a home of the churlers, for its persecution of the Jews, and for its Nihilist sympathies.

**Odepoor.** See *Udaihpur*.

**Odillon-Barrot.** See *Barrot*.

**Odin** (Odhin; O. H. Ger. *Wotan*; Sax. *Wodan*, or *Woden*—whence *Wednesday*), the chief god of northern mythology, common to all Germanic peoples. He is not the creator of the world, but its ruler, king of heaven and earth. Odin, as
the highest of the gods, the *Alfdator*, rules heaven and earth, and is omniscient. As ruler of heaven, his seat is the palace Hildisvinda in Angard, from where he rules over the heavens. His twin is the armed warrior Munin (Memory), by whom daily to gather tidings of all that is being done throughout the world. As god of war, he holds his court in Valhall, whither come all brave warriors after death to revel in the tumultuous joys in which they too of lost pleasure while on earth. His greatest treasures are his eight-footed steed Sleipner, his spear Gungnir, and his ring Draupner. As the concentration and source of all greatness, excellence, and activity Odin bears numerous different names. By drinking from Minir's fountain he became the wisest of gods and men, but he purchased the distinction at the cost of one eye. He is the greatest of sorcerers, and imparts a knowledge of his wondrous arts to his favourites. Friggs (q.v.) is his queen, and the mother of Balder (q.v.), the Scandinavian Apollo; but he has other wives and favourites, and a numerous progeny of sons and daughters. He is claimed as ancestor of various royal dynasties. Rhys contends that the myths relating to Woden, the great Teutonic sky-god, may be traced to a Celtic origin, and that certain elements of Woden are carried on through Celtic Gwydion. See SCANDINAVIAN MYTHOLOGY.

**Odoacer.** ODOACAR, the ruler of Italy from the year 476 to 493, was the son of Edico, a captain of the Germanic Scyri. He entered the military service of the western Roman empire, and rapidly rose to eminence. He took part in the revolution by which Orestes (475) drove the Emperor Julius Nepos from his throne and was acclaimed Emperor by the Romans with the title of Augustus, which the people scoffingly changed into Augustulus. He soon perceived the weakness of the new ruler, and at the head of the Germanic mercenaries—Heruliens, Rugians, Trevelingians, and Scyri—marched against Pavia, which Orestes had garrisoned, stormed the city, and put his opponent to death (476). Romulus abdicated, and withdrew into obscurity. Thus perished the Roman empire. Odoacer showed himself to be a wise, moderate, and politic ruler, some of his conduct was later praised by Zeno and, with the title of *Patricius*, ruled Italy from Ravenna. The barbarian ruler did everything in his power to lift Italy out of the deplorable condition into which she had sunk. Though an Arian himself, he acted with a kindly impartiality towards those who differed from him. He protected the monasteries, which had rarely existed. He conducted a successful campaign in Dalmatia, and against the Rugii on the Danube. The increasing power of Odoacer excited the jealousy and alarm of Zeno, who encouraged Theodoric, king of the Ostrogoths, to undertake an expedition against Italy (489). Odoacer, defeated in three great battles (at Isonzo, at Verona, and on the Adda), shut himself up in Ravenna, which he bravely defended for three years. Compelled by famine, he capitulated (493) on condition that the kingdom of Italy should be shared between him and Theodoric. For a fortnight a most extraordinary conjecture was entertained at a feast by Theodoric himself. See Hodgkin, *Italy and her Invaders*.

**Odometer.** See PEDOMETER.

O'Donnell, LEOPOLD, Marshal of Spain, born at Teneriffe, 12th January 1809, was descended from an ancient Irish family. He entered the Spanish army when young, and espoused the cause of the infant Queen Isabella against Don Carlos (see CARLISTS). When the Carlists were overthrown he was created Chief of the Staff to Espartero. He took the side of the queen-mother in 1840, emigrated with her to France, and took up his residence at Orleans, where he planned many of the political risings which took place under the rule of Espartero. In 1843 his intrigues against Espartero (q.v.) were successful; and he was rewarded by the governor-generalship of Cuba, where he amassed wealth and fortune by favoring the negro slave trade. When he returned to Spain (1848) he intrigued against Bravo Murillo and Narvaez; was made war minister by Espartero in 1854; but plotted against his benefactor, and in 1856 supplanted him by a coup d'état. He was in three months' time succeeded by Narvaez, but in 1858 he returned to power; in 1859 he commanded the army in Morocco, and after a tedious campaign took the Moorish camp, and the city of Tetuan surrendered, whereupon he was made Duke of Tetuan. In 1866 his cousin was upset by Narvaez, and he died at Bayonne, 5th November 1867.

**Odontopteryx** (Gr. *odon*, 'tooth'; *pteryx*, 'a wing'), a goose-like or duck-like bird, the remains of which occur in the London clay (see EOCENE SYSTEM). The alveolar margins of both jaws are furnished with tooth-like projections which are actual parts of the bony substance itself, and, therefore, not like true teeth. The tooth-like serrations, of two sizes, are of triangular or compressed conical form, and are all directed forwards.

**Odontornithes,** extinct toothed birds from the Cretaceous strata of North America. There are two distinct families—Hesperornis and Hesperornis. The former and its relative Aptornis were small tern-like flying birds, with teeth in sockets, and with biconcave vertebrae. But Hesperornis was a large bird, about six feet long, with utterly degenerate wings and obviously incapable of flight. According to Marsh, to whom our knowledge of these forms is chiefly due, it was a consummate diver, even more aquatic than the penguin. The teeth are set in grooves, the vertebrae saddle-shaped. A bird indeed,' Stejneger says, 'but a kind of swimming,loon-like aquatic ostrich, without fore-limbs, with the gape armed with formidable rows of straight teeth like a gigantic lizard, and with a large, broad, and flattened tail like a beaver.' See Marsh's monograph (1889).

**Ecolampus.** JOANNEUS (the Latin form of HAUSSECKEN, although his proper name was Hussgen), belonged to the same University of Basel as two of the juniors of Zwingli in the Swiss Reformation, born in 1482 at Weinsberg, in Swabia. He relinquished the study of law at Bologna for that of theology at Heidelberg, became tutor to the sons of the Elector Palatine, and was subsequently preacher in Weinsberg. Being appointed preacher at Basel, he formed the acquaintance of Erasmus, who employed him as assistant in his edition of the New Testament. In 1516 he left Basel for Augsburg, where also he filled the office of preacher, and where he entered into a convent. But Luther's publications exercised so great an influence on him that he left the convent, and became chaplain to Franz von Sickingen, after whose death he returned to Basel in 1522, and, in the capacity of preacher and professor of Theology, commenced his career as a reformer. He held disputations with supporters of the Church of Rome in Baden in 1526, and in Bern in 1528. In the controversy concerning the Lord's Supper he gradually adopted more and more the views of Zwingli. In 1529 he disputed with Luther in the conference at Marburg, and published several treatises. He died at Basel, 24th November 1531. He was remarkable for his gentleness of character. There are Lives in German by Herzog (1843) and Hagenbach (1859).

**Ecumenical.** See ECUMENICAL.

**Ede'a** (Gr. *a swelling') is the term applied in medicine to the swelling occasioned by the effu-
Oedipus (Gr. Oidipous), the hero of a legend which supplied subjects for some of the noblest tragedies of Sophocles and Euripides. Oedipus was the son of Laius, king of Thebes, by Jocasta, the sister of Creon, and was exposed after his birth, with his feet pierced through, on Mount Citharon, because the king had learned from an oracle that he was doomed to perish by the hands of his own son. The child was discovered by a herdsman of Polybus, king of Corinth, and was named (Oedipus) from his swollen feet. Polybus brought him up as his own son. Being told by the oracle at Delphi that he was destined to slay his father and commit incest with his mother, he would not return to Corinth, but proceeded to Thebes to escape his fate. As he drew near the city the chariot of the king, and the charioteer ordering him out of the way, he struck him, and Oedipus unwittingly slew Laius. In the meantime the famous Sphinx had appeared near Thebes, and propounded a riddle to every one who passed by, putting to death all who failed to solve it. In the terror of despair the Thebans offered the kingdom, together with the hand of the queen, to whoever should deliver them from the monster. Oedipus offered himself, whereupon the Sphinx asked him, 'What being has four feet, two feet, and three feet; only one voice; but whose feet vary, and when it has most, is weakest?' Oedipus replied that it was man. The Sphinx then threw herself headlong from the rock on which she sat. Oedipus became king, and husband of his mother, Jocasta. From their incestuous union sprung Eteocles, Polynices, Antigone, and Ismene. A mysterious plague now devastated the country, and, when the oracle declared that before it could be stayed the murderer of Laius should be banished from the country, Oedipus was told by the seer Tiresias that he himself had both murdered his father and committed incest with his mother. In his horror he put out his own eyes, that he might no more look upon his fellow-creatures, while Jocasta hanged herself. He wandered towards Attica, accompanied by his daughter Antigone, and at Colonus near Athens the Eumenides charitably removed him from earth.

Ehlerschläger, ADAM GOTTLOB, Danish poet, was born 14th November 1779 in a suburb of Copenhagen, where his father, a Slovicker, was an organist. After an irregular and desultory course of education, he tried unsuccessfully the career of an actor, and then took to law studies, but soon devoted all his energies to the cultivation of the history and poetry of his own country. In 1803 appeared his first collection of poems; and the Fantasiers Saga (1805) and Aladdins forande Lampe raised him to the rank of the first of living Danish poets. These early efforts were rewarded by a travelling pension, which enabled him to spend some years in travelling the Continent, and becoming acquainted with Goethe and other literary celebrities. During this period Ehlerschläger wrote his HdtensJuel, the first of his long series of northern tragedies (1807; Eng. trans. by F. C. Lascelles, 1875), and at Rome his Correggio (1809; Eng. trans. by Theodore Martin, 1884). In 1810 Ehlerschläger returned to Denmark, where he was bailed with acclamation, and made popular the poems of Atheslæg. In 1814 took place his literary feud with Baggesen (q.v.). In 1819 appeared one of his most masterly productions, Nordens Guder, which showed that the severe criticism to which his writings had been exposed during the celebrated Baggesen quarrel had corrected some of the faults, and lessened the self-conceit which had characterised his earlier works. His reputation spread with his increasing years both abroad and at home. In 1829 he went to Sweden, where he was welcomed by a public ovation; and he was honoured in his own country in 1840 by a grand public festival in the palace at Copenhagen. He died 20th January 1850. His fame rests principally on his twenty-four tragedies, most of them on northern subjects. Besides those already referred to, the best are Grundtvigens Christian (1819); Adeltofte, der Erindrende, Væringerne i Miklagard. His lyrical and epic poems are of less value. His Poetiske Skrifter were edited in 1837-62 in 62 vols.; the German translations were done by himself. An Autobiography appeared in 1830-31, his Reminiscences in 1850; and there are Lives by Arendzen (1879) and Nielsen (1879). His Danish and German works amount in all to 62 volumes.

Oehler, GUSTAV FRIEDRICH, one of the greatest Old Testament scholars of the 19th century, was born at Ehingen, 10th June 1812, studied at Tübingen, laboured as a teacher at Basel and Tübingen, became in 1840 professor in the theological seminary in Sébenthal, and in 1845 ordinary professor of Theology at Breslau. In 1852 he was called to Tübingen to be head of the theological seminary, and here he died, 19th February 1872. The chief books of this learned and reverent scholar were Petrie, Einleitung zur Theologie der alten Zeugnisse (1845), Die Grundzüge der Alt-testamentlichen Weisheit (1854), Uber das Verhältniss der A. T. Prophetie zur heidnischen Munit (1861), Theologie des Alten Testaments (1873-74; Eng. trans. 1874-75), and Lehrbuch der Symbolik (1876). See the sketch by Knapp (1874); the life by E. Hoppe (1876).

Eland, a long and narrow island in the Baltic, 4 to 17 miles from the east coast of Sweden. It is 53 miles long and 5 to 12 broad; pag. 37,513. Scarcely more than a limestone cliff, it is scantily covered with soil, but in some parts it is well wooded, and has good pasture ground; there are large alun-works; and the fishing is excellent all round the coasts.

Oels, a manufacturing town of Prussian Silesia, 16 miles E.N.E. of Breslau by rail. Pop. 10,276.

Eunthic Ether. See Ether.

Enothiera, a genus of ornamental plants of the natural order Onagraceae, related to the Fuchsia (q.v.), though strikingly dissimilar in general appearance. E. Moschata, a native of Virginia, has been known in Europe since 1614, and is now naturalised in many parts of Europe and in some parts of Britain, on the banks of rivers, in thickets, on sandy grounds, &c. The flowers are fragrant in the evening. The root contains a principle in saponin, but without it is usually red, fleshy, and tender, and is eaten in salads, or in soups, and as a boiled vegetable. Eaten after dinner it incites to wine-drinking, as olives do. This and numerous other species of
Ofthelma, chiefly natives of North America, are very generally cultivated in English flower-gardens.

Oera Linda Book. See Frisians.

Onrebro, a town of Sweden, at the entrance of the Svarta into the Hjelmar Lake, 170 miles W. of Stockholm by rail. It has an ancient castle, in which many diets have been held; and there is a trade in minerals and matches. Pop. 13,618.

Oersted, Hans Christian, physicist, was born 14th August 1777, at Rudkjöbing, on the Danish island of Langeland, and studied medicine at Copenhagen, where in 1806 he was appointed extra-ordinary professor of Physics. He held numerous scientific appointments and honorary offices and distinctions, and died 9th March 1851. He may be regarded as the father of the science of electro-magnetism (see Electricity, Vol. IV. p. 263), and made numerous chemical discoveries. Of his many works the best known are Naturlarenens Mechaniske Deel (1843; 3d ed. 1859) and Anderen i Naturen (1830). His collected works were translated into German in 6 vols. (1850–53). There is a biography by Hanch and Forchhammer (1853).—His brother, Anders Sandoe (1778–1850), was a distinguished Danish statesman.

Oscol, an island in the Baltic belonging to the Russian government of Livonia, and lying across the mouth of the Gulf of Riga. It is about 43 miles in length from north-east to south-west, has an area of 1000 sq. m., and a pop. of 50,000. The surface is undulating, broken by low hills, marshy, watered by numerous small streams, and wooded. The coast is generally formed by high cliffs. The climate is colder than that of the neighbouring continental districts. The only town is Arensburg, on the south-east coast (pop. 4000). Many of the inhabitants of Arensburg are of German descent, as are the nobles and clergy of the island; but the peasantry are Estonian. Long governed by the Teutonic Knights, it became a Danish province in 1559, was given up to Sweden in 1645, and in 1721 fell into the hands of Russia.

Osophagus, or Gullet, a membranous canal about 9 inches in length, which extends from the pharynx to the stomach, and forms the part of the alimentary canal. See Digestion, Vol. III. p. 814; and Choking.

Estria. See Bot.

Oetinger, Christoph Friedrich, theosophic theologian, was born in 1702 at Göppingen, and, after holding various curers, died at Murrhardt, 10th February 1782. His sermons (5 vols.) were published in 1737, and his collected sermons (7 vols., edited by Elmann) in 1858–67. His system has been described as lying between Jacob Boehme and Schelling. See monographs by Auberlin (1848), Elmann (1852; 2d ed. 1877), and Wächter (1885).

Ofen. See Pestil.

Offa's Dyke, an entrenchment extending along the border of England and Wales, from the north coast of Flintshire, on the estuary of the Dee, through Denbigh, Montgomery, Salop, Radnor, and Hereford, into Gloucestershire, where its southern termination is near the mouth of the Wye. In some places it is nearly obliterated by cultivation; in others it is of considerable height. Nearly parallel with it, some two miles to the east, is Watt's Dyke, which, however, seems never to have been so great a work. Offa, King of Mercia, it is said to have ordered Watt's Dyke in 765 to keep back the Welsh, and Offa's Dyke for the enemy. Offenbach, a manufacturing town of Hesse-Darmstadt, on the south bank of the Main, 5 miles by electric railway SE. of Frankfurt. Among its manifold industrial products are chemicals, fancy leather goods, machines, and carriages. The schlöss is a residence of the princely House of Eisen-\n
Birstein. Pop. (1831) 7502; (1875) 36,012; (1890) 35,079.

Offenbach, Jacques, a composer of opera bouffe, born of Jewish parents at Cologne, 21st June 1819. He came to Paris in 1833, and settled there, being appointed chef d'orchestre at the Opéra in 1837; became conductor in 1841; was director of the Académie de Musique at Marseilles in 1842; took charge of the Opéra in Paris in 1848, and manager of the Opéras Parisiennes in 1855. He died 5th October 1880. Offenbach composed a vast number of light, lively operettas, La Mariage aux Lutins, La Fille d'Exode, &c., perfect as musical trifles; but the productions by which he is best known are a series of burlesque operas, in virtue of which he must be regarded as the inventor of the modern form of opera bouffe. Amongst the most notable are Orphée aux Enfers (1858), La Belle Hélène, La Barbe à papa, La Grande Duchesse, Geneviève de Brabant, and Boïelle, Madame Pompadour (1878) became almost as popular in England as in France.

Offertory (Lat. offertorium, from offero, 'I offer') is the name given to that portion of the public liturgy of the Roman Catholic Church with which the eucharistic service, strictly so called, commences (see Liturgy). This offering of the bread and wine in the public service became, from a very early period, the occasion of a voluntary offering, on the part of the faithful; originally, it would seem, of the bread and wine designed for the eucharistic services of the day. This, however, is the practice in the Roman Catholic Church of the mass-offering, or honorarium, which is given to a priest with the understanding that he shall offer the mass for the intention (whence the honorarium itself is often called an 'intention') of the offerer. See also Collections.

Officers, Military and Naval.—Military Officers are combatant and non-combatant, the latter term including paymasters, medical officers, commissariat, and other departmental officers. The great divisions of rank in the British army are commissioned and uncommissioned officers. Commissioned officers hold commissions from the crown, and comprise all of the rank of second-lieutenant or corresponding or superior rank. Some warrant officers also hold honorary
Officinal Plants

OGAM

This word is sometimes written Ogham, but it should then be pronounced with a gh mute, as in modern Irish, to which the spelling Ogham belongs. In English, however, it is preferable to pronounce the y, and to spell the word Ogam, as in older Irish; then there will be the noun Ogam and the adjective Ogmic, for which we have the sanction of such authorities as Whitley Stokes and Nigra.

The term Ogam is associated with Ognn, the champion of the mythical Tuatha Dè Danann—i.e., the tribes of the goddess Danu, or Don as she is called in the Maltingon of the Welsh. Ognia's name is, letter for letter, the Irish equivalent of Omnia, the name of the Gaulish divinity quaintly described by Lucian as a Celtic Hercules, which meant a Hercules who performed his feats by dint of eloquence, not by the force of his arms. So the Gauls pictured him leading crowds of willing recruits, who, however closely they might copy the two different accounts of the Ogam, as the Irish sometimes treated z and at as equivalents, as, for example, when they wrote stelo, Stephanus, and Elisabeth for zeta, Zephyrus, and Elizabeth. It should be explained that at has long been commonly reduced in Irish words to z or s. Thus we have the Irish tradition respecting this Ogam seems to mean that, it was z or a certain other sibilant. Now, as to z representing the soft sound corresponding to the sharp sound of ss, it is not to be found in Irish from the 6th century down, and it is doubtful whether it existed in the language late enough to gain a place in the Ogam alphabet. We venture to accept the indication afforded by Irish tradition, that *** was a sibilant, or let us

Thurneysen should be read in the Revue Celtique (vol. vii. p. 369-374), proves to have been a jargon of artificial and pedantic origin. It is needless to say that the efforts of these physicians, like most other attempts at an invention to Ogam can have formed no part of early Irish tradition about Ogam; and, as there is no reason to suppose the Ogam alphabet to date till late in the Roman occupation of Britain, much the same remark must apply to the invention of that form of writing. It is not hard, however, to see why both came in the course of time to be ascribed to Ogam: he was, like his Gaulish namesake, probably a hero of words, of speech, and of eloquence, so that any linguistic invention might readily gravitate into association with his name.

Putting aside the Ogam dialect, we shall now confine our remarks to the Ogam alphabet, promising that the key to it was never lost in Irish literature, though little attention was devoted to it by scholars till after the discovery of the bilingual inscription at St Dogmael's, near Cardigan, in South Wales. But in Irish manuscripts the values of the Ogam characters are naturally given as those of the Irish letters in the pronunciation familiar to the writers of those manuscripts; so when we deal with Ogamns, let us say, of the 5th or the 6th century, certain corrections have to be made to the equivalents. The following is the Ogam alphabet, with the value of each symbol as it has been ascertained from the most ancient class of the monuments in question:

<table>
<thead>
<tr>
<th>a</th>
<th>b</th>
<th>c</th>
<th>d</th>
<th>e</th>
<th>f</th>
<th>g</th>
<th>h</th>
<th>i</th>
<th>j</th>
<th>k</th>
<th>l</th>
<th>m</th>
<th>n</th>
</tr>
</thead>
</table>

On this let us remark that the continuous line represents the edge of the stone on which the digits are cut. Taking an Ogam stone in situ, one must commonly read upwards, and the scores are placed on either side of the edge. In some instances the vowels are not mere notches in the edge of the stone, but scores of nearly the same length as those of the third group, but differing from them in being cut perpendicular to the edge, to suggest some reason for the slanting of the digits of the third group, but that is not supported by the most ancient class of inscriptions. Turning to the individual characters, the value of a given to the first of them is derived only from Irish tradition, but there is no reason to doubt its accuracy, as the writer has never come upon any good inscriptional evidence in point. The same, till lately, might be said of the case of ng, but he has found *** in an ancient inscription for the nasal in the borrowed word, *** ** ****, Soneli. The case of *** is one of some difficulty, as the letter has never been found in an inscription, while Irish tradition ascribes it the value of z or ss, however closely they might copy the two different accounts of the Ogam, as the Irish sometimes treated z and at as equivalents, as, for example, when they wrote stelo, Stephanus, and Elisabeth for zeta, Zephyrus, and Elizabeth. It should be explained that at has long been commonly reduced in Irish words to z or s. Thus we have the Irish tradition respecting this Ogam seems to mean that, it was z or a certain other sibilant. Now, as to z representing the soft sound corresponding to the sharp sound of ss, it is not to be found in Irish from the 6th century down, and it is doubtful whether it existed in the language late enough to gain a place in the Ogam alphabet. We venture to accept the indication afforded by Irish tradition, that *** was a sibilant, or let us

Commissions. Classified by duties, they are staff or regimental officers; divided by rank, General Officers (q.v.), Field-officers (q.v.), and troop or company officers. The latter are divided into lieutenants, captains, and sub-lieutenants. Warrant officers in the army are master-gunnners (1st and 2d класс), bandmasters, schoolmasters, garrison and regimental sergeant-majors, superintending clerks, and conductors of the army service and ordnance store companies.

No commissioned officers are described under that head.

Naval Officers are divided into three classes: commissioned, warrant, and subordinate officers. The commissioned officers are admirals, captains, commandants, lieutenants, sub-lieutenants, chief warrant officers, paymasters, doctors, engineers, and naval instructors. All officers of the civil branches of the navy, as paymasters, doctors, and engineers, rank relatively with officers of the military branch according to their standing in the service, as, for instance, an inspector-general of hospitals ranks with a rear-admiral, a chief-paymaster with a captain, and so on. The warrant officers are the boatswains, gunners, and carpenters. The third class comprises midshipmen, naval cadets, clerks, and engineer students; these officers have neither commissions nor warrants, but are simply appointed by the Admiralty. They are made in a probationary term, and are liable to be summarily removed at any time for such causes as failure to make satisfactory progress in their studies, general inefficiency, &c. No officer of the civil branch, no matter how high may be his relative rank, can ever assume any command, so long as an officer of the military branch is present. Petty officers are not officers, they are analogous to non-commissioned officers in the army; they will be described under their own heading, as they constitute a very important body of men in the navy.

Officinal Plants (Lat. officina, 'a shop') are those medicinal plants which have a place in the pharmacopoeias of different countries, and which are therefore sold—or some of their products or preparations of them—by apothecaries and druggists. The medicinal plants cultivated to any considerable extent are all officinal, but many are also officinal which are not cultivated.

Offsets. See Surveying.

Ofterdingen, Heinrich von (c. 1400), one of the minnesingers (q.v.).

Ogam. This word is sometimes written Ogham, but it should then be pronounced with an gh mute, as in modern Irish, to which the spelling Ogham belongs. In English, however, it is preferable to pronounce the y, and to spell the word Ogam, as in older Irish; then there will be the noun Ogam and the adjective Ogmic, for which we have the sanction of such authorities as Whitley Stokes and Nigra.

The term Ogam is associated with Ognn, the champion of the mythical Tuatha Dè Danann—i.e., the tribes of the goddess Danu, or Don as she is called in the Maltingon of the Welsh. Ognia's name is, letter for letter, the Irish equivalent of Omnia, the name of the Gaulish divinity quaintly described by Lucian as a Celtic Hercules, which meant a Hercules who performed his feats by dint of eloquence, not by the force of his arms. So the Gauls pictured him leading crowds of willing recruits, who, however closely they might copy the two different accounts of the Ogam, as the Irish sometimes treated z and at as equivalents, as, for example, when they wrote stelo, Stephanus, and Elisabeth for zeta, Zephyrus, and Elizabeth. It should be explained that at has long been commonly reduced in Irish words to z or s. Thus we have the Irish tradition respecting this Ogam seems to mean that, it was z or a certain other sibilant. Now, as to z representing the soft sound corresponding to the sharp sound of ss, it is not to be found in Irish from the 6th century down, and it is doubtful whether it existed in the language late enough to gain a place in the Ogam alphabet. We venture to accept the indication afforded by Irish tradition, that *** was a sibilant, or let us
say an s, for that is the only sibilant known to the language, except sh, which is written s preceding e or i; we must therefore look for a class of words where the actual or attested s of Irish stands for a consonant which was at one time not an sibilant, as in borrowed words, like srian, 'a bridle,' from the Latin frexum, or seinistir, 'a window,' from the Latin fenestra. But the change from f to s is not confined to borrowed words, as there is a group of words with s in modern Irish corresponding to words with Latin g, e.g., Irish gann, Welsh gwenn, 'a staff,' in which the initial combination of consonants seems to have been at first sp or sp-h. This would seem to have been simplified into f or ph, and that ultimately changed into s. We should accordingly be inclined to believe that f or ph was the value of the Ogam

; and the phonetic change afterwards into s would account for the sibilant value ascribed to this Ogam by Irish tradition. Moreover, a genitive Fanóni in a Devonshire inscription, reading in Roman letters FANONI MAQVIRINI, shows that early Irish had the sound of f or ph; and as the Ogam alphabet provided no symbol for it, unless it was , this consideration confirms the conclusion already suggested. It is right here to remark that nowhere Irish has the consonant f, but in earlier Irish this was s or r, which between vowels has since been everywhere elided, while initially it has been strengthened into f; thus, in Adamnan's Life of St Columba the name Ferghna is Ferphna, while the ancient Terra Cualcuireua appears in the Annals of the Four Masters as Tir-Couille, or rather Tir-Couille-Cerd, to distinguish it from the district of Tironnell in Donegal. As to the Ogam , which we have transliterated gu, that combination, when written in Latin capitals, is found represented by QV, as in the MAQVIRINI, already cited; the exact pronunciation of the u cannot be ascertained, but it was probably not very far from that of the English u, as in one instance the QV is represented in Ogam by or in one other by gu or u. In any case, it is worthy of note that no instance of confounding or with is known to occur in the more respectable class of Ogam inscriptions. Lastly, a character x occurs, which, as it were, outside the Ogam alphabet of twenty symbols. In Ireland this x had two values: sometimes it represented one of the sounds of e and sometimes the consonant p; the latter was also its value in South Wales, where it occurs in the Ogmic spelling of the genitive of the Roman name Turpilus. In Goidelic words themselves it cannot have been often wanted, as the p of the Aryan parent speech is nowhere retained in the Celtic languages. It is noticed, however, that in some words the place of Aryan p was occupied in Old Irish by x; e.g. xuile, 'all,' from the same stem as the Greek παίλλος, 'many,' and huathad, 'the singular number,' from the same root as Latin unus, English one.

A word must now be said of the distribution of Ogam monuments. All the Ogam inscriptions, whether in stone, on metal, or on wood, consist of epitaphs. Of that number about 250 belong to Ireland, mostly the southern counties, especially Kerry, Cork, and Waterford, though one or two are as far north as Londonderry. The Ogams in British islands make rather less than fifty in all, and of these South Britain has none cast of Wales and Devon. Within this area the county which has most specimens to show is Pembrokeshire (including Caldy Island), and next in order come the other South Welsh counties and Devon, while Cornwall boasts only a single instance, and that of a somewhat doubtful nature. No Ogams have been found in Mid-Wales, and only one is known in North Wales, viz. near Ruthin, in the county of Denbigh. The Ogams of Wales, however, and Devon have an importance out of all proportion to their number, owing to the fact that most of them are accompanied by a version in Latin. Proceeding backwards, one comes across a highly interesting group of Ogams in the Isle of Man: but the first Scotch Ogam is a very doubtful one, to be found, as it is supposed, on the island of Gigia, between Caithyre and Islay. There are, however, about fourteen Ogams mentioned as belonging to Scotland, most of which have no doubt attaching to them as to their being Ogams, though more don't than enough exists as to the import of some of them, or even to the language employed. They occur in the counties of Aberdeen, Elgin, and Sutherland, also in the islands of Orkney, and more frequently in those of Shetland.

The writer once thought that Ogmnic and Runic writing could be traced to a common origin; but he no longer thinks so. In his opinion the most probable theory is that which regards the Ogam alphabet as invented during the Roman occupation of Britain, by a Goidelic grammarian who had seen the Brythonic of the Roman province making use of Latin letters. The Celts were in the habit of setting up stones to mark the tombs of their great men, but it was presumably from the Romans they learned to inscribe them. It has been supposed that the inventor of the Ogam alphabet took a hint from a habit of scoring for the purpose of counting, and that his group , the five first numerals, which in modern Irish are aon, dé, trí, ceathair, cheig, for this only required one to regard aon as if it were houin, with an h prefixed according to a habit by no means uncommon in the case of certain letters in Old Irish. Such a theory proves on examination to be substantially tenable, as the early Goidelic forms of the numerals in question were approximately the following: aíns, do, trí, ceats, quegue. The fourth, ceats, represented an earlier gets, corresponding to the Latin quattuors, and ceats, standing as it originally did in an unaccented syllable, was dropped, so that the word became ceto's. The case of the initial gu of the fifth

The Newton Stone, Aberdeen-
The specimens of Ogams from Shetland are found to have been so written; and as the edge of the stone would be represented in manuscript by a continuous straight line, we find a grid of scratches on the flat part of the stone, and the Ogams arranged in connection with it instead of following one of the edges. So it is improbable that prepared pieces of wood formed the usual material for cutting Ogams, as they seem to have been cut out in one piece, and the Ogams were arranged in connection with it instead of following one of the edges. It is needless to mention that Ogam is not a new form of shorthand: a few hands could well be longer; and it ought likewise to be needless to say that there is nothing cryptic about this method of writing. It is a pretty general rule, for example, that a compound word of four syllables in the fifth or sixth century A.D. appears as a word of two in the modern dialects of Gothic, so that an Ogam genitive *Lugnuartic* is later met with compressed into *Luehid*. Here the changes which have taken place are in harmony with the ascertained rules of Irish phonology, and no Celtic scholar would think of saying that *Lugnuartic* is a cryptic form of *Luehid*: that would be simply to deny the history of the word any phonological perspective, and so in other cases. Lastly, for the study of Gothic philology the importance of the Ogam inscriptions is not to be overlooked, and as they are, it is much the same as that of Roman inscriptions would be for Romance philology, supposing all other remains of Latin speech had utterly perished.

The most comprehensive work on Ogams is Dr. Brough Ogam-inscrípts of the Far and the British Islands, with a Dissertation on the Ogam Character (Lond. 1879); and next to it in point of comprehensive- ness must be ranked Sir Samuel Ferguson’s Ogmns In- scriptor of Ireland (Lond., 1887); and the Ogam Inscription of Ireland, which consists of the Rhind Lectures delivered in Edin- burgh in 1884. Papers on Ogams will be found in the Trans. Roy. Irish Acad., especially by the Bishop of Limerick, who has also published a theory of the origin of Ogmic writing in the *Hermathena*. The journal which has above all others kept its pages open for Ogam finds in Ireland is that of the Royal Hist. Assoc. Ireland (originally founded as the Academy and the Manx Note-book; and papers on the Scottish Ogams were read before the Society of Antiquaries of Scotland in the years 1882-84 by the Earl of Sutherland after careful examination of the stones. The facts given in the Ogham Inscriptions of Ireland have been discussed in detail in Rhys’s Lectures on Welsh Philology (Lond. 1879); and some Ogam forms have been used for the purposes of Celtic philology by Dr. Whitley Stilgoe in his Celtische Deistichten. Ogams are thus the most important Irish tract on Ogams to be found in the 15th-century manuscript known as the Book of Ballymote; it contains folios 308-314 of the substance cited, &c. (I. O. 1887) of that extensive codex.

**Ogaswara.** See Boxin.

**Ogdien, capital of Weber county, Utah, is situated, at an elevation of 4340 feet, at the confluence of the Weber and Ogden rivers, where the former passes through the Widsatch Mountains, 37 miles N. of Salt Lake City. It is of importance chiefly as a terminus of the Northern Pacific railroads, as well as three others, join. The city contains a Methodist university (founded 1890), a foundry and several mills, breweries, and
manufactories of woolens, brooms, boots and shoes, &c. Pop. (1880) 6069; (1900) 16,313.

Ogdensburg, a port of New York, on the St Lawrence, at the mouth of the Oswegatchie, opposite the town of Ogdensburg, county of St Lawrence, New York. It is founded by Francis Du Four, who established there a colony in 1665, and was given by the French to New York in 1763.

Ogée, Ogive. Ogée is the name given by the French to the pointed arch; and as an English architectural term, ogive ribs are the main ribs which cross one another at the intersection of the vaulting. Ogée, a form of the curve, is applied to a compound curve, made up of a convex curve continued by a concave one. Ogival work is common in the Decorated Style (q.v., fig. 3), and may be seen in the tracery of the Flamboyant (q.v.). The ogee moulding is that also called Cyma reversa, illustrated at MOULDING. The French word is from the Spanish ojivo, and that from the Arabic al-ajwīn, 'arch.'

Oger le Danois. See CHANSONS DE GESTES.

Oglethorpe, James Edward, founder of Georgia, born at Lavenham, county of Kent, England, October 16, 1696, the son of Sir Theophilus Oglethorpe, of Godalming in Surrey. After studying awhile at Oxford he joined the Guards before he was twenty, and served on the Continent with Prince Eugene. From 1722 to 1734 he represented Haslemere in parliament. He then went to America, where he died at the siege of Savannah, in 1745. Oglethorpe's work was to found a colony in America, where the debtors then languishing in English gaols might start life afresh, and which should be a refuge for the persecuted German Protestants (see SALZBURG). Parliament contributed £10,000. George II. gave a grant of the necessary land, after him called Georgia; and in 1733 Oglethorpe went out with a company of 130 persons and founded Savannah. In 1735 he took out 300 more, including the two Wesleys; and in 1738 he was back again with a regiment of 600 men, raised in anticipation of a war with Spain, from whose neighbouring colony of Florida he had already received annoyance. War was declared by the mother-countries in 1739, and in 1741 Oglethorpe invaded Florida and unsuccessfully attacked St Augustine (see his own account, published 1742); the war was again suspended by a preliminary peace concluded in 1748. In 1743 he left the colony for the last time, to meet and repel before a court-martial the malicious charges of one of his own officers. He was again tried and acquitted after the Forty-five for having failed, as major-general, to overtake Prince Charles's army. The cluster of his colony he surrendered to the British government in 1752. His later years were spent at Cranham Hall, his seat in Essex, where he died on 30th January 1785. His intimate friends included many of the most eminent men of the day. Pope's compleat is well known:

Or driven by the wafted winds,
Will fly, like Oglethorpe, from pole to pole.

D. Johnson urged him to write his life, and even offered to do it himself; and Boswell made a few, but insufficient, notes with the same object.

See Lives by Harris (Boston, 1841), Wright (Lond. 1867), and Bruce (New York, 1890).

Ogowo, or Ogoway, a river of West Africa, has its origin on the west side of the watershed that separates the western from the eastern part of the Sahara, in lat. 40° 5 S., 14° 30' E. long., flows north-west, and finally curves round by the south so as to pour its waters into the Gambia at Banana, on the north side of Cape Lopez. It forms a wide delta of some 70 sq. m. in extent. In the dry season (July to Sep-
tember) it shrinks to a narrow current winding between the rocky obstructions of its bed; at other times it is a deep, broad stream, navigable by boats; numerous rapids and sandbars and shallow prevent vessels of any size from ascending it. It has been dominated by France, through her colony on the Gambia (q.v.), since 1885.

Ogyges, the earliest legendary king of Attica and Beotia, in whose time a great flood took place called the Ogygian Flood.

Ogygian, a genus of Trilobites (q.v.), peculiar to the Lower Silurian rocks. See BRACHIPODS.

O'Hara, Theodore, author of 'The Bivouac of the Dead,' was born at Danville, Kentucky, in 1820. He was a lawyer and journalist, but served as captain and major in the Mexican war, afterwards, for a year, in the United States cavalry, and in the civil war as a colonel on the Confederate side. He died in 1867. See monograph by Rauke (Baltimore, 1875), and the Century (May 1890).

O'Higgins. See CHILI.

Ohio, a river of the United States, called by the French explorers, after its Indian name, la Belle Rivière, next to the Missouri the largest affluent of the Mississippi, is formed by the union of the Allegheny, Monongahela, and Ohio rivers, the last-named at Pittsburgh, Pennsylvania, and flows west-south-west 975 miles, with a breadth of 400 to 1400 yards, draining, with its tributaries, an area of 214,000 sq. m. In its course it separates the northern states of Ohio, Indiana, and Illinois from the southern states of West Virginia and Kentucky. The principal towns upon its banks are Pittsburgh, Wheeling, Cincinnati, Louisville (where there are rapids of 22 feet in a mile, with a steamboat canal), Evansville, New Albany, Madison, Portsmouth, Covington, and Cairo. The river's principal affluents are the Tennessee, Cumberland, Wabash, Kentucky, Great Kanawha, Green, Muskingum, and Scioto. It is usually navigable from Pittsburgh.

Ohio, a state of the American Union, the fourth in population, lies between 38° 25' and 42° N. lat., and 80° 30' and 84° 30' W. lat. It stretches from north to south 210 miles, and from east to west 220 miles; the northern and southern and much of the eastern boundaries are irregular. Area, 41,000 sq. m., or equal to that of Ireland and Wales together. Ohio is a part of the original large territory. Under charters granted by the English kings, each territory became a corporate body soon after the formation of the Virginia colony; and when that colony became a state, the territory, with undefined northern limits, became a county. Ohio was the first state created within the territory,—of which it comprises much of the best part. It is watered on the north by Lake Erie, and on much of the east and all of its southern boundary by the Ohio River, from which it derives its name.

The face of Ohio, taken as a whole, presents the appearance of an extensive, monotonous plain. It is moderately undulating, but not mountainous; in many places streams have forced a way through bold cliffs of sandstone. A low ridge enters the state near the north-east corner and crosses it in a south-west direction. This 'ridge' separates the waters of Lake Erie and the Ohio River, and maintains an average elevation of a little over 1300 feet above sea-level. North of this ridge the surface of the country is generally level, gently declining toward the lake. The central part of Ohio is almost a level plain, about 1000 feet above the sea, slightly inclining southward. The southern part is somewhat hilly, the valleys growing deeper as they approach the Ohio River, whose tributaries here water many extensive and fertile
valley. There are a few prairies or plains in the north-western part of the state, but over its greater portion originally existed immense quantities of timber. The principal rivers draining southward to the Ohio are the Muskingum, Scioto, Great Miami, and Little Miami. Northward to the lake are the Tuscarawas, Cuyahoga, Sandusky, Huron, and Maumee, all but the last named being entirely in the state.

The rocks underlying Ohio belong to the Silurian, Devonian, and Carboniferous systems. The general arrangement of the geological formation shows a layer of sheets resting in the form of an arch, or a great dome, over Ohio. The beds of limestone (No. 4) midway in the state is unbroken, and stretches from side to side; the Oriskany, the Coniacian, the Hamilton, and Huron formations, though generally removed from the crown of the arch, still remain over a limited area near the central portion.

On the side of the great anticlinal axis the rocks dip downward into a basin, which for several hundred miles, north and south, occupies the interval between the Nashville and Cincinnati ridges and the first fold of the Alleghany Mountains. As they dip toward the centre of this trough, oil is in the state is first struck in the strata of the older rocks are deeply buried, and the surface is here underlaid by the Alleghany coal-measures; while in the north-western part of the state the strata dip northward and pass in the same way under the Michigan coal-basin. The coalfields of Ohio in the state is first struck in 1837, 1,000,000 long tons were mined in 1867. Immense deposits of limestone, freestone, and mill-stones abound.

Archaeologically Ohio is the richest field in America. In no other state have been found so many evidences of man, his implements of stone, bone, copper, and clay; while the most extensive and elaborate systems of earthworks in America are at Newark, near Chillicothe, and on the Miami bluffs near Waynesville. See MOUND-BUILDERS.

Ohio is one of the chief manufacturing states in the Union, leading all others in the manufacture of farm machinery, carriages and wagons, woolen and cotton goods, furniture, and wine and spirits. It has also great rolling-mills and iron-foundries, glass-factories, potteries, and oil-works. In agricultural machinery it stands first in the Union in most regards. Its annual production of maize is some 90,000,000 bushels, of wheat 40,000,000, of wool over 20,000,000 lb. Cattle and hogs are reared in large numbers. Ohio is a leading pork-producing state. The oil-fields, prevailing largely in the north-west, are being rapidly developed, and already the output is second only to that of Pennsylvania. Natural gas has been found in immense quantities, but at the present rate of consumption is soon exhausted.

History.—In 1768 the Ohio Company of Associates was organized in New England by those who had served in the war of the revolution, and under their auspices a large tract of land was purchased from the government in the territory north-west of the Ohio River, payment being made in 'Continental Certificates' issued by the federal government. This was the first public sale of land by the United States government. In connection with its sale the famous 'Compact' or 'Ordinance of 1787' was passed, guaranteeing for ever in the territory civil and religious freedom, the system of common schools, trial by jury, and the right of inheritance. In 1788 Marietta and Cincinnati were founded, and till 1791 settlements in the southern part of the territory increased rapidly. In that year the Indians became troublesome, owing to the continual encroachments of the whites, and an army under the governor suffered a disastrous defeat. In November 1788 a signal victory was gained by General Anthony Wayne over the Indians at 'Fallen Timbers' on the Maumee River. The year after a treaty of peace was concluded at Fort Greenville, the Indians ceding a great portion of territory, which settlers began at once to fill, and the towns of Xenia, Dayton, Hamilton, and Dayton and Columbus followed. Their limits and others were established. Chillicothe was made the seat of government for the territory, and a capital building erected. In 1802 a constitution was adopted for the 'Eastern Division of the Territory North-west of the Ohio,' to be known as 'Ohio.' In 1803 the state was formally admitted into the Union. By 1810 its population was 230,760, and the increase from that period was rapid. As early as 1812 steamboat navigation up and down the Ohio River was accomplished; by 1834 there were, as now, 700 miles of canal in operation; and the Mad River Railroad, begun in 1837, was opened for traffic in 1842, and completed to the lakes by 1848; in 1857, 5729 miles of railway traversed the state, not counting double tracks, &c. Ohio has given five presidents to the Union—Grant, Hayes, Garfield, Benjamin Harrison, and Grover Cleveland.

Ohio is divided into 88 counties, and returns 21 members to congress. The justices of the supreme court are elected for terms of five years by the people. The state has several universities and numerous colleges, with professional, art, and commercial schools. The school population in 1887 was 1,088,000; attendance, 56 per cent. The ratio of illiteracy is less than the average of other states. The largest cities are Cincinnati, Cleveland, Columbus (the capital), Toledo, Sandusky, Dayton, and Akron. The currency is that of real and personal property in 1890 was $1,778,138,477. Pop. (1890) 1,969,539; (1870) 2,665,260; (1890) 3,672,316; (1900) 4,157,545.

Ohio, a town of Prussian Silesia, 20 miles SE. of Breslau by rail, on the Oder. Pop. 8575.

Ohm, GEORGE SIMON, physicist, born at Erlangen, 16th March 1787, became in 1849 professor at Munich, and in 1854 at Berlin. For Ohm's Law and the ohm as a measure of electric resistance, see ELECTRICITY, Vol. IV. p. 267.

Ohnet, GEORGES, a French novelist of great popularity, if not merit, born 3d April 1848 at Paris. He studied law, and after practising some time as an advocate took to journalism, and later to literature proper. Under the general title of Les Batailles de la Vie he has published a series of novels dealing comprehensively with social questions, some of which have actually reached a hundredth edition. The first in this cycle of romances was Serge Passe (1881), then quickly followed by Le Miroir de la F LNG (1882), La Couronne de la Terre (1883), Lise Fleuron (1884), La grande Mousse (polisière) (1885), Les Dames de la Croix-Mort (1886), and Volonté (1888).

Odium, or ERYSIPHE, a genus of minute fungi infesting various plants, and especially important as the cause of a ravaging disease of the vine, popularly known as vine-mildew. The disease was first observed in Kent in the spring of 1845; it spread rapidly over the English vineyards, and was observed about the same time in the vineyards of Paris, and soon afterwards in those of nearly all parts of France, Italy, Greece, Tyrol, and Hungary, and in many vineyards in the Rhine valley. Its ravages extended to Algeria, Syria, Asia Minor, and especially to the island of Madeira, where it nearly put an end to the production of the celebrated wine. The disease appears first in the leaves, those drop off, the plant loses strength
through impaired nutrition, the young shoots fall withered and lastly the grapes. Powdered sulphur was found useful as a cure, but the applications had to be very frequent; in consequence of its importance the duty of sulphur was reduced by the French government. It is probable that in this case, as in all diseases of this nature, the general vitality of the individual must be lowered before it will fall a victim. Over-cultivation and long use of the same ground are predisposing causes.

**Oil-beetle.** A name given to beetles of the Melo and allied genera, which when disturbed emit a yellowish oily liquor from the joints of their legs. Some species are used as vesicants instead of anticharids.

**Oil-bird.** See Guacharo.

**Oil-cake** is used mainly for feeding sheep and cattle. It is made from the solid residue of oleaginous seeds (linseed, rape-seed, cotton-seed), after a large proportion of their oil has been extracted. The following is the usual process of manufacture in Britain. The seed is crushed and ground upon a mill of the following construction. Two large circular blocks of hard granite are set edgewise on a bedstone of the same material, which is slightly hollowed out; these two upright stones are connected by a horizontal shaft which passes through the centre of both, and is fixed at its middle to a revolving upright shaft. The stones are thus made to revolve about their vertical axes, while at the same time they are left free to be turned round the horizontal shaft by the friction of grinding. The meal thus formed is heated in kettles formed of two compartments, in the inner of which the meal is placed, while the outer is filled with steam. The meal is then filled into small wooden bags of the shape it is wished to make the cakes—usually oblong, about 20 inches by 12 inches, and 2 to 3 inch thick. These bags are then placed in wooden "wrappers," which consist of two pieces of hard wood, of the same size as the cakes, hinged together at the end; the wood is usually corrugated and furnished with a stamp to mark the cakes. The wrappers containing the crushed oil-seed are then placed in the compartments of a press worked on the same principle as a Hydraulic Press (q.v.), except that the oil from the seed is used instead of water. In this way about 90 per cent. of the oil in the seed contains is squeezed out of it by heating to a high temperature and pressure; and by washing the ground husks into a solid firm cake. Sometimes the process is varied, in that the seed, instead of being ground under stones, is repeatedly crushed on iron rollers; in this case the crushed seed is steamed in the kettles to give the necessary moisture, not merely heated as described above. Sometimes oil-seeds are subjected to a chemical instead of a mechanical process—viz. solution of the oil in bisulphite of carbon. By this means the oil may be almost completely extracted. Mustard, rape, castor oil, unoleicaric oil, seed-cake, and some other oils and are used as fertilisers.

**Oil City, Pennsylvania,** on both sides of the Alleghany River (here crossed by long railroad and passenger bridges), 133 miles by raii N. by E. of Pittsburgh, is one of the principal oil markets in the state, and the centre of a busy trade. It contains, besides oil-refineries, cotton-oil, and vegetable oil factories, a large number of temperers. There were fearful inundations here in June 1892. Pop. (1870) 2270; (1880) 7315; (1900) 13,264.

**Oil-fuel, Oil-gas.** See Fuel, Gas-lighting, Petroleum. For Oil-engine, see Gas Engine.

**Oil Palm.** See Oils, and Palm.

**Oil Rivers.** See Niger.

**Oils** (including Fats). The fats and fixed oils constitute an important and well-marked group of organic compounds, which exist abundantly both in the animal and vegetable kingdoms. They are not simple organic compounds, but each of them is a mixture of several such compounds to which the term **glycerides** is applied. The general term **oils** by which they are known as a result of their mixture in various proportions form the numerous fats and oils are mainly those of palmitic, stearic, and oleic acids, and to a less extent those of other fatty acids, such as butyric, caproic, caprylic, and capric acids, which are obtained from butter, myristic, and lard oil, which is obtained from coconut oil, &c. The members of this group may be solid and hard, like suet; semi-solid and soft, like butter, horse-grease, and hard; or fluid, like the oils. The solid and semi-solid are, however, usually placed together as termed fats in contradistinction to the fluid oils. The most solid fats are readily fusible, and become reduced to a fluid or oily state at a temperature lower than that of the boiling-point of water. It is not until a temperature of between 560 and 600° F. is reached that they burn with a bright flame. In a pure state, and which, from their being able to bear distillation without change, are known as **volatile oils.** These, which are also known as essential oils, differ in toto in their chemical composition from the compounds we are now considering. All volatile oils are lighter than water, and are perfectly insoluble in that fluid. Their specific gravity ranges from about 0.91 to 0.94. They dissolve in ether, oil of turpentine (one of the volatile oils), benzol, and to a certain extent in alcohol; while, on the other hand, the oils of the Cruciferae, &c., These bodies possess the property of penetrating paper and other fabrics, rendering them transparent, and producing what is well known as a greasy stain. They are not readily inflammable unless with the agency of a wick, then they burn with a bright flame. In a pure state and fresh state they are devoid of taste and smell, but on exposure to the air they become oxidised and acid, assume a deeper colour, evolve a disagreeable odour, and are acid to the taste; or, in popular language, they become rancid.

**Rancidity with its effects.** These effects are considerably increased by the presence of mucilaginous or albuminous bodies. The rancidity may be removed by shaking the oil in hot water in which a little hydrosulphate of magnesium is suspended.

The general diffusion of fats and oils in the animal kingdom has been already described (see FATS). In the vegetable kingdom they are equally widely distributed, there being scarcely any tissue of any plant in which traces of them may not be detected; but they are specially abundant in the seeds of the Cruciferae. These seeds are remarkably rich in oil; linseed yielding fully 20 per cent., and rape-seed about 40 per cent. of oil; and some fruits, as those of the olive and oil-palm, yield an abundance of oil.

The uses of oils and fats are numerous and highly important. They are extensively employed as articles of food, as medicines, as lubricating agents, in the preparation of soaps, ointments, varnishes, pigments, for candles, lamps, and other means of illumination, and for the purpose of dressing leather, &c. In Asia, Africa, and the Pacific archipelago this change occurs is considerably increased by the presence of mucilaginous or albuminous bodies. The rancidity may be removed by shaking the oil in hot water in which a little hydrosulphate of magnesium is suspended.

and the attacks of insects, and checking excessive perspiration. This practice conduces to health and preserves the skin smooth and soft. Oil thrown on the sea has a remarkable effect in subduing the force of the waves. A few gallons cast upon a burning ship and thrown to the wind breaks with force. This practice might be adopted by lifeboats when approaching wrecks, and rescuing the crews of stranded vessels. The composition of the fine oils required for watches and sewing-machines is often carefully kept secret. Thinning with melted olive, hemp, or neats-foot. The oils suitable for machine-shops and general cotton and woollen machinery require a good body, rather viscous. For woolen spindles a lighter oil, and for cotton spindles, which have a speed of 4000 revolutions per minute, an oil of still lighter body. For lubricating purposes mineral oils may with advantage be mixed with animal and vegetable oils to diminish their tendency to thicken; the more fluid an oil is the less friction takes place.

1. Vegetable Oils.—The chief solid fats of vegetable origin are coconut-nut oil, nutmeg-butter, cocoa-butter, and palm-oil. The fluid vegetable fats or oils are divisible into the non-drying and the drying oils; the latter being distinguished from the former by their becoming dry and solid when exposed to the air and to the influence of heat or oxygenation. Some of the drying oils, when mixed with cotton, wool, or tow, absorb oxygen so rapidly, and consequently become so heated, as to take fire, and many cases of the spontaneous combustion of heaps of oily materials that have been employed in cleaning machinery have been recorded. The chief non-drying oils are olive-oil, almond-oil, and colza-oil; while the most important drying oils are those of linseed, hemp, poppy, and walnut; castor-oil seems to form a link between these two classes of oils, since it gradually becomes hard by long exposure to the air.

2. Animal Oils.—The chief solid fats are beef and mutton suet or tallow, hard, butter, goat’s grease, &c.; while among the fluids sperm-oil, ordinary white-oil, cod-liver oil, and neats-foot oil may be especially mentioned. In many of their characteristics and uses, these resemble the solid fats. As a general rule, stearin and palmitin, both of which have comparatively high fusing points (between 157° and 114° F.), preponderate in the solid fats; whilst olein, which is fluid at 32°, is the chief constituent of the oils. Woods and vessels, when heated with the hydrated alkalies undergo a change which has long been known as Saponification, or conversion into Soap (q.v.), in which the fatty acid combines with the alkali to form a soap, while the remaining viscous liquid glycerine is simultaneously formed. When the fatty acids are required on a large scale, as for the manufacture of the so-called stearin candles, which in reality consist mainly of stearic and palmitic acids, sulphuric and the oil or fat are made to act upon each other at a high temperature (see CANOLA). The fatty acids may also be procured in a very pure form by the injection of superheated steam at a temperature between 500° and 600° into heated fat. A complete list of even the chief fats and fixed oils would take up far more space than we can command. The more important are noticed, such as Fixed Oil of Almonds, Castor-oil, Cotton-oil, &c., and some account given of their properties and uses; or under the names of the substances from which they are procured—Linseed, Rape, Candle-nut, Coco-nut, Cotton (for Cotton-seed Oil). Oils not used may be made to the articles on Butter, Ghee, Lard, Cod-liver Oil, &c.

The Volatile or Essential Oils exist in most instances, ready formed in plants, and are believed to constitute their odorous principles. They form an extremely numerous class, of which most of the members are fluid. Many used for flavouring are artificially compounded (see BUTYRIC ACID). There are several important for flavouring liqueurs and confectionery, and for various purposes in the arts. They will be described at PERFUMERY. The mineral oils will be found discussed under the heads of Naphtha, Paraffin, Petroleum.

OILS. N. THE COMMERCIAL RELATIONS.—

Vegetable Oils.—The principal seeds imported for expressing oil are cotton, linseed, rape, and ground-nut; but many others are received in small quantities. Cotton-seed is now a very important product, which was formerly much neglected. The imports into Britain rose from about 20,000 tons in 1861 to over 314,000 tons in 1890, nearly all coming from Egypt: 100 lb. of seed yield about 2 gal. of oil. The seed fetches 5s. to 6s. a ton; the oil 2½ to £21 a ton. Linseed.—British imports of linseed meal in 1890, £2,659,000, or 10,946,000 cwt., of the value of £4,000,000. Nearly all the oil supplied to obtain from Russia, which produces the best seed, but now the chief imports are from India; these arrive, however, very much mixed with rape and other seeds. India ships about 85 million cwt. of linseed oil to Britain, and the Pacific islands the coco-nut oil of commercial value. Oils are also imported for the albumen or ripe kernel of the nut, known in commerce when dried as copra. The production of this oil does not make the same progress that oil-palm does, as the following commercial imports into the United Kingdom will show: 1870, 388,682 cwt.; 1880, 445,934 cwt.; 1883-90, the price of the oil declined about 10 in 1883-90, the price being in the latter year 27s. per ton. Palm-oil.—The average imports of this oil are 50,000 tons annually. Prices have advanced of late years, and in 1890 stood at 22s. per ton. This oil is chiefly used for washing the greases used for railway axles. Rape-seed.—The imports of rape range between 450,000 to 2,300,000 qrs., of which about half come from Russia and half from India. The total exports of this seed from India now exceed 5 million cwt., valued at nearly £2,000,000 sterling; the great bulk of this is sent to France and Belgium. From the first pressure rape-seed will yield about 90 lb. of oil per quarter, and from a second pressure 60 to 70 lb. The Ground-nut (Arachis hypogaea) is now a large source of oil-supply, but the principal commerce and manufacture centre at Marseilles. It is principally cultivated on the west coast of Africa, but is now much grown in India. The price of the shelled kernels in the London market is from £11 to £13 per ton. Olive-oil used to be one of the most valuable vegetable oils, but has now much declined in price, and is replaced with or replaced by Ginge! and cotton-seed oils. The average imports are about 20,000 tons, the best Spanish fetching £37 per ton. For lubricating and woollen manufactures olive-oil has been largely replaced by other vegetable oils and hard oils. OLIVE, the Geraniol or Tol-oil is the produce of the seed of Stearum indicum, which yields about 50 per cent. of oil; and
the animal export of this seed from India is from 1½
to 22 million cwt. It goes principally to France and
Italy. The price is 40s. to 50s. the 384 lb. *Popp y-
seed. The trade in this seed is chiefly between India
and the United States, ranging from 450,000 to 730,000 cwt.;
the exports are chiefly to France and Belgium.
The seeds yield 45 per cent. of oil, which is used for
culinary purposes. The seed sells at about 43s. the
bushel of 383 lb. *Castor-oil seed.—From 609,000
bushels of this seed, valued at about £87,000, are
exported annually from India, and 2,000,000 to 2,500,000 gal. of the
castor-oil. The expression of the oil is chiefly carried on in Italy and America, besides India.
A large quantity of *Amber is also exported, from which a
very important manufacture of *Amber is obtained.
A large quantity of *Soja is also obtained from the countries of
the world, and serves as a substitute for *Soja in
the manufacture of *Soap. The oil of *Soja is used for
the manufacture of *Soap, and also for the preparation of
animal food. It is a very important article of commerce, and
is largely used in Europe and America.

**Animal Oils.**—The principal solid animal oils
found in commerce are butter and tallow, tallow, mares' grease,
and salt-oil, and unsaturated yolk of egg oil. They are
also produced under many names. Tallow is the fat of oxen
and sheep, and especially the fat which envelops the kidneys
and other parts of the viscera, rendered down or melted.
The qualities of this solid oil make it particularly
well adapted for making candles, and until the
end of the first quarter of the 19th century
the candles for ordinary use were almost wholly made
of it. Britain obtains probably about 60,000 tons
of tallow yearly at home, and receives as much
from abroad, chiefly imported from North
and South America and Australia. The
imported tallow is the chief
source of supply of animal fats. The imports of
tallow and stearin do not vary greatly from year
to year; they were, in 1870, 1,525,208 cwt.;
1880, 1,516,379 cwt.; 1890, 1,585,517 cwt.
The value of the last crop was
£1,720,349. The oleins, obtained by pressure
from animal fats, are known in commerce as tallow-
olein, lard-olein, and salt-olein oil; they come
next in value to sperm-oil. The two former are
indispensable in making soaps. Many thousand tons
of these oleins are sent from the United States
to Europe for artificial butter-making. Besides the
home production of butter, which is large
(about 130,000 tons), the United Kingdom imported in
1890 over 100,000 tons, valued at £10,500,000,
electric lighting. Fish oils are valuable for soap-making and also much employed by furriers for dressing leather; and the oil is again recovered and sold for further use under the name of degree and seed oil. Sharks are largely caught off the Norwegian coast and in the Indian seas, chiefly for their oil. It is caught after they are dead, and their livers yielding 2500 barrels of oil, which is much valued for lubricating. Spermæctis, or ‘head matter,’ as it is commercially termed, from the oil being principally found in the enormous head of Physeter macrocephalus, has, like whale-oil, been deemed valuable. Britain only receives some 1450 tons, valued at £56,325, against three times that quantity imported about the year 1880. It was used to be much employed in candle-making, mixed with about 5 per cent. of beeswax to prevent crystallisation (see Whale). Seal-oil is hence included with raw or fish oil. The exports from Newfoundland range from 3500 tons to 6000 tons yearly, according to the catch of seals. In 1889 Great Britain imported from that island 7000 tons of oil, valued at nearly £57,000. There was a large decline in 1890, only 50 per cent. of the prices of the years 1880-90. The current prices in 1890 per ton of 252 gallons were, for spermaceti, £45 to £46; whale-oil, £21 to £23; and cod-oil, £24 to £26; and cod-oil, £22. The medicol-cod liver oil realises higher prices. Fuller information on the preparation of spermaceti will be found under the various heads. In 1878 the British manufacture of fish oils of all kinds was 20,656 tons, valued at £10,594; in 1890, 20,992 tons received were only valued at £41,290. In various quarters a considerable quantity of oil is obtained from different birds, such as the albatross, the penguin, seals, and species of Procellaria, the Guanaco, the goose, ostrich, emu, and rhea, the passenger pigeon, and others; but, with the exception of penguin-oil from the Falklands, none of these appear to any extent in commerce, and are only used locally. The large and growing importance of the oil trade is manifest from a consideration of the statistics of imports and exports alone in a year, independent of the various industries and labour interested therein. Taking the English Board of Trade figures for 1889, we find that the value of the imports and exports including butter and butyrous fats, in lumber, tallow, &c., amounted to £18,309,518, the vegetable oils to £3,718,074, the mineral oils to £2,963,334, and the nuts and seeds imported for expressing oil to £2,269,678, making a total of £33,310,240. The imports are nearly all used in Britain, the re-exports being insignificant compared with the value of £3,331,242. If to this we add the £1,701,106 for oil-seed cake imported, and the export of oil, soap, and candles of British manufacture, amounting to £2,557,095, we have a total capital involved in the trade of over £27,550,000, and this, quite irrespective of the home production of tallow, butter, fish oils, and the like.

Olonomia. See Dipsomania.

Oilments are fatty substances intended to be applied to the skin by rubbing in, and having the consistence of butter. The material employed as a basis for the ointment varies considerably, and as a rule the activity and action are entirely due to the substance incorporated therewith. The basis, most generally used basis is lard, either alone or mixed with wax, &c., to give it more consistence. To avoid raneculity the lard is usually melted previously with gum-benzoin, and is then known as benzoinated lard. Though lard is readily assorbed by the skin, yet in this respect it is surpassed by sheep's wool fat and Oleic Acid (q.v.). The former of these, when incorporated with water, forms an excellent ointment base, smooth, and in every way suitable. So also some of the uctuous oleates are used with great advantage. Soft paraffin, known in commerce under a number of names, has also been used for ointments and does not turn rancid, but on the contrary is even extended. As nearly all substances may be made into ointments, there is no limit to their number, but perhaps the best known are Zinc Ointment (q.v.), Boracic Ointment, and the Red and White Precipitate Ointments (see Precipitate Ointment). In all cases the greater is the extent to which the active principle is rubbed perfectly smooth with a small quantity of oil or lard before adding the bulk of the ingredients, otherwise the production of a homogenous ointment free from grit is impossible. See Cold Cream.

Oise. a department in the north of France, separated from the English Channel by Seine Inférieure; area, 2261 sq. m.; pop. (1881) 404,555; (1901) 401,533. The principal rivers are the Oise, a tributary of the Seine, 150 miles in length, with the Aisne and Thérain, affluents of the Oise. The soil is fertile, and agriculture advanced. The products are the usual grain-crops, with an immense quantity of vegetables, which are sent to the markets of the metropolis. There are extensive iron manufactures; porcelain, paper, chemicals, beet-root sugar, woollens, cottons, and lace (at creches); and plants are also made. The department is divided into the four arrondissements of Beauvais, Clermont, Compiègne, Senlis; capital, Beauvais.

Oka, an important navigable river of central Russia, the principal affluent of the Volga from the south, rises in the government of Orel, and flows in a generally north-east direction, and joins the Volga at the city of Nijni-Novgorod, after a course of 706 miles. Its basin comprises the richest and most fertile region of Russia. The principal towns on its banks are Orel, Bielew, Kaluga, Riazan, and Morun; the most important affluents are the rivers Moscow, Klissma, and Tza. During spring the Oka is navigable from Orel to Novgorod, but in summer the navigation is obstructed by sandbanks.

Okayango. See Ngami.

Okeechobee, a lake of Florida (q.v.).

Oken (originally Ockenfuss), LORENZ, naturalist, was born at Hohlsbach, in Baden, August 1, 1779. He studied at Wurzburg and Göttingen; became extraordinary professor of Medicine at Jena in 1807; in 1812 he was appointed ordinary professor of Natural Science; and in 1816 he commenced the publication of a journal partly scientific and partly political, called Iris, which led to government interference and his resignation. In 1822 he obtained a chair in Medicine in the newly-established university of Munich, but in 1832 exchanged it for another at Zurich, where he died 11th August 1851. Oken aimed at constructing all knowledge a priori, and thus setting forth the system of nature in its universal relations. His system of natural science is a nature-philosophy, which, though decried as transcendental and a deduction from foregone conclusions, was fertile in suggestive ideas. It was he who wrought out the theory, claimed by Goethe, and now exploded, that the skull is but a modified vertebra.

Oken's works are his Lehrbuch der Naturphilosophie (1838-11; Eng. trans. 1847), his Lehrbuch der Naturgeschichte (3 vols. 1813-27), and Allgemeine Naturgeschichte (17 vols. 1835-45). See works on Oken by Ecker (1880) and Guttler (1884), and see Sir Richard Owen's article in the Encyclopaedia Britannica.
OKHTOSK, SEA OF, an extensive inlet of the North Pacific Ocean, on the east coast of Russian Siberia, nearly enclosed by Kamchatka and the Kurile and Kerguelen. It is little navigated.

On its northern shore is the mouth of the Okhotsk, the smallest seaport of Okhotsk, with a pop. of 300.

Okinawa, an organised territory of the United States of America, is bounded W. and S. by the state of Texas, E. and S.E. by the territorial waters of the United States, and by Indian Territory, and N. by the territorial waters of the United States of the Gulf of Colorado. The territory includes the Western portion of Indian Territory, together with the Public Land Strip N. of the Texas pan-handle. This strip, ceded to the United States by Texas at the time of its annexation, was by an oversight not included in any of the adjacent states or territories, and until its incorporation in Oklahoma Territory was known as No Man's Land. The area of Oklahoma is 39,030 sq. m. The population in 1890 was 61,834 persons, including 5335 in Greer county, between the forks of the Red River and Canadian; it has been augmented. The federal census of 1900 showed a population of 398,331.

The surface, which rises gradually toward the north and west, is for the most part an upland province. The most important elevations are the Wichita Mountains, in the southern part of the State. One of Oklahoma ("Beautiful Country") has been much overrated. It is fairly well watered by the Red and Arkansas rivers and their affluents, but many of the streams are brackish, and so saturated with alkali salts as to be unfit for drinking purposes or for irrigation. The rainfall is much lighter and also less uniform than in Indian Territory. In the river-valleys and in some of the upland regions there are fertile and productive spots, but much of the region is likely to be subject to the same disappointment which prevails in western Kansas during unfavourable seasons. The so-called Public Land Strip, formerly the refuge of desperadoes, is now the civilized Beaver county, a rich agricultural and stock country, though subject to sudden changes, produced by the "dry" climate of the land, which is the climax of Oklahoma ("Beautiful Country") has been much overrated. The improvement is directly due to the exertions of the 40 young woman teachers in the public schools.

The history of Oklahoma dates from the year 1866, when the tribes to whom the lands of Indian Territory had previously been granted ceded the western part of their domain to the United States. The land thus acquired was known as the Oklahoma district, but it was agreed that it should be used only for settlement by other Indian tribes or freedmen. Notwithstanding this stipulation western speculators claimed that the lands were the property of the government, and open, like other public lands, for settlement under the Homestead (q.v.) laws. In 1879 an organised effort was made to take forcible possession of the lands, and adventurers from Texas, Kansas, and Missouri, equipped, and armed to the teeth, invaded the territory. Their action was forbidden by proclamation from President Hayes, and the intruders were finally ejected by United States troops. From this time until his death in 1884, David L. Payne, the leader of the "boomers," was repeatedly defeated, humiliated, imprisoned and returned to the forbidden land, with the number of his followers augmented. He is said to have received more than $100,000 in fees from persons who secured from him permission to settle in Oklahoma. After his death the invasions were continued with the aid of the U.S. military. Although the government repeatedly proclaimed the integrity of the treaties with the Indians and enforced them by the authority of the military, negotiations were opened, as a result of which, upon the receipt of an additional sum, the Indians waived all claims to a district in the heart of Indian Territory. This unoccupied area was opened for public sale in October 1889, and the school was established at Edmond. Educational facilities have grown with the territory. There is a territorial university at Norman; there are three normal schools, at Edmond, Alva, and Langston; Stillwater has an agricultural and mechanical college; and many schools are found in the towns of size, with high schools in the cities. In 1897 there were 90,585 children of school age, and (1898) there were 1879 organised school districts. The annual income from the school lands amounts to an average of $290,000. Oklahoma presents an unprecedented instance of a commonwealth created almost in a mature condition at a moment's notice. In an incredibly short space of time the wilderness was transformed into a region of productive farms and populous towns. Guthrie, the capital, and Oklahoma City, were each once a mere Indian trading post. Norman, El Reno, Kingfisher City, Stillwater, Beaver, Perry, and Enid are among the rapidly growing centres.

Okra, a name for the Hibiscus (q.v.) esculentus. Olaf, the Saint, one of the most revered of the early Norwegian kings, was born in 995, and after having distinguished himself by his gallant exploits, and made his name a terror in several war-like expeditions against the coast of England, succeeded, in 1015, in wresting the throne of Norway from Eric and Svend Jarl. The cruel severity with which he endeavoured to exterminate paganism by fire and sword alienated the affections of his subjects, who hastened to tender their allegiance to Canute of Denmark on his landing in Norway in 1028. Olaf fled to the court of his brother-in-law, Jaroslav of Russia, who gave him a band of 4000 men, at the head of whom he returned, in 1030, and gave Canute battle at Stiklestad, where Olaf was defeated by the aid of his own subjects, and slain. His body was removed to the cathedral of Trondheim, where the fame of its miraculous power spread far and wide; and Olaf was solemnly proclaimed patron saint of Norway in the succeeding century. See Nasjonal Bibliografisk Data Olais, edited by F. Metsalfe (Oxford, 1881).

Oland. See Gland.

Olaus. For Olaus Magnus, see Magnus; for Olaus Petri, see Sweden (Literature).

Obers, Heinrich Wilhelm Matthais, physician and astronomer, was born at Arbergan, a village of Bremen, October 11, 1758, studied medicine at Göttingen from 1777 till 1783, and openly practised at Bremen. In 1811 he was a successful competitor for the prize proposed by Napoleon for the best 'Memoir on the Croup.' He became known as an astronomer by his calculation of the orbit of the comet of 1778. He discovered the planet Pallas (1802) and subsequently the planet Uranus (1877); and in 1781 he had the honour of first rediscovering the planet Uranus. He also discovered five comets in 1798, 1802, 1804, 1815, and 1821, all of which, with the exception of that of 1815 (hence called Obers' comet), had been previously observed. His observations, calculations, and notices of various comets, which are of inestimable value to astronomers, were published in various forms. Obers also made some
important researches on the probable lunar origin of meteoric stones, and invented a method for calculating the velocity of falling stars. He died at Bremen, 20 March 1815, with a good conscience with Benjamin Franklin (1753).

Old Bailey, the court or sessions house in which the sittings of the Central Criminal Court are held monthly for the trial of offences within its jurisdiction. The judges of this court are the Lord Mayor, the Lord Chancellor, the judges, aldermen, recorder, and common serjeant of London. But of these two, the serjeant, or the judge, is in the sheriff's court are in most cases the actually presiding judges. The judicial sittings here are of such antiquity that all record of their commencement has been lost. Crimes of all kinds, from treason to petty larceny, are tried, and the numbers in past times were enormous, but are now greatly reduced by the extended jurisdiction given to the quarter sessions, and the summary powers granted to magistrates. Here were tried in 1669, after the Restoration, the surviving judges of Charles II.; and Willett in the assize of 1812, the Cato Street conspirators in 1820. The Old Bailey dinners given by the sheriffs to the judges were long famous. However else varied, they always included beefsteaks and marrow puddings, and were served twice a day. The Old Bailey, like the libels and novels, has been, since Holben Viaduct and Ludgate Hill. Prisoners awaiting trial at this court are transferred to Newgate for the sake of convenience whilst the sessions here are sitting.

Old Believers. See Raskolnik.

Oldbury, a busy manufacturing town of Worcestershire, 5 miles N.W. of Birmingham, stands in the midst of a rich mineral district, and has iron and steel works, besides factories for railway plant, edge-tools, chemicals, &c. Pop. (1851) 11,741; (1851) 18,841; (1891) 20,348. See J. Nicholls' History of Manor and Parish (1791).

Oldcastle, Sir John, once popularly known as the 'good Lord Cobham,' whose claim to distinction is that he was the first author and the first to use the English name in English history, was born in the reign of Edward III.; the exact year is not known. He acquired the title of Lord Cobham by marriage with the heiress of the line, and signified himself by the Angola of his attachment to the doctrines of Wyclif. At that time there was a party among the English nobles and gentry sincerely, even strongly, desires of ecclesiastical reform, whose leader was 'old John of Gautem—time-honoured Lancaster.' Oldcastle was active in the same cause, and took part in the presentation of a remonstrance to the English Commons on the schismatical and heretical acts of the church. At his own expense he got Wyclif's works transcribed, and widely disseminated among the people, and paid a large body of preachers to propagate the views of the Reformer throughout the country. In 1411, during the reign of Henry IV., he commanded an English army in France, and forced the Duke of Orleans to raise the siege of Paris; but in 1413, just after the accession of Henry V., he was examined by Archbishop Arundel, and condemned as a heretic. He escaped from the Tower into the 'good years' hiding was captured. He was brought to London, and—being reconciled a traitor as well as a heretic—was hung up in chains alive upon a gallows, and, fire being put

under him, was burned to death, December 1417. Oldcastle wrote Twelve Conclusions addressed to the Parliament of England, several monastic hymnological livell man, and twelve religious discourses, &c. Halliwell-Phillips first proved in 1841 that Shakespeare's Sir John Falstaff was originally Sir John Oldcastle—a view endorsed in Gairdner and Spedding's Studies (1881).

Old Catholics (Ger. Altkatholiken) is the title assumed by a number of Catholics who at Munich protest against the dogma of the personal infallibility of the pope in all ex catholica deliverances, proclaimed by the Vatican Council in 1870. It now applies to a communion or church in Germany and Switzerland, which has grown to be considerable in numbers and influence. The Munich protest by forty-four professors. Dr. Döllinger and Professor Friedrich at their head, was directed against the binding authority of the Vatican Council and the validity of its decrees. To the Munich protest a number of Catholic professors at Bonn, Breslau, Freiburg, and Giessen declared their adhesion. The leaders of the movement met at the end of August at Nurenberg and drew up a declaration. The German bishops, though they had given warning of the dangerous consequences of the proclamation of the new dogma, submitted to the decision of the Vatican Council, and in September 1870, called upon all members of the faculty of Catholic theology to sign their allegiance. Against the refractory (numerous professors and one priest) they proceeded by suspending them from their functions, and then by excommunication. The Prussian governments, however, took their respective subjects, the objects of those measures, under their protection.

At first the masses of the priests and laity showed very little sympathy with the Old Catholic congregations declaring their dissent from the decrees of the Vatican Council. Pamphlets and appeals issued by the heads of the party elicited but little response. Local committees in furtherance of the cause were, however, formed in several towns in Bavaria and the Rhine. At a general Old Catholic Congress, held in 1871 at Munich, it was resolved to draw the bonds of union close with the church of Utrecht, the Jansenists (q.v.) of the Netherlands, which, under its archbishop and two bishops, offered to the Old Catholics of Prussia a church, and offered to be received with confirmation. The congress, while carefully eschewing any decided breach with traditional dogma, and professing the desire simply to maintain the church as it stood before the 18th July 1870, profound the far-reaching principle that the decisions of an ecumenical council, to be valid, must be in agreement with the existing faith of the Catholic people and with theological science. The hope was also expressed of a reunion with the Greek Oriental Church and a gradual understanding with the Protestants. Old Catholic congregations that had been formed in different towns of Bavaria and the Rhine country. In 1872 the Old Catholic priests in the German empire numbered about thirty. The Archbishop of Utrecht in July made a tour in Germany, holding religious service in Protestant churches and confirming some of the churches were of the Old Catholic congregation at Cologne, 1872. Professor Friedrich declared that the Old Catholic movement was now directed not merely against papal infallibility, but 'against the whole papal system, a system of errors during a thousand years, which had spread on the church like an infallibility.' Döllinger, the leader of the movement was led to the formation of the new
communion, at first disapproved of the establishment of a new sect, but ultimately approved of the action of his friends. Yet till his death he never formally joined the community.

At Cologne in 1873 Professor Reinkens of Breslau, and 1823, which represented Old Catholic priests and by representatives of the Old Catholic congregations. He was consecrated at Rotterdam by the bishop of Deventer, and formally acknowledged by the governments of Prussia, Russia, and Austria. The government declined to forbid Bishop Reinkens holding confirmations in their kingdom. The third congress at Constance in 1873 was taken up with 'syndal and communal regulations,' and with projects towards union with other Christian confessions. There were numerous guests present, Anglican, Russian, and German Protestant clergy. On the basis of the decrees of this congress the first Old Catholic Synod was held at Bonn in 1874, being composed of thirty priests and fifty-nine laymen. They laid down principles for reforms in general, abolished auricular confession and compulsory fasting, and appointed two commissions to draw up a new ritual in the vulgar tongue, and to frame a Catechism and a Bible History. A formula of agreement drawn up at another conference of 1875 rejected a proposal for an Old Catholic synod. The third and fifth congresses (those of 1876 and 1878) permitted priests to marry, and yet fulfil all ministerial functions, in spite of Jansenist protests. After 1876 the numbers declined. In 1875 there were in Germany 62,000 Old Catholics; in 1890 some 36,000, in 79 congregations. In Switzerland (where a theological faculty was established at Bern in 1874 and a bishop consecrated in 1876) there were in 1890, 53 priests and 45,700 members (against 73,000 in 1877). In Austria there were in 1891 about 16,000, mainly in Bohemia. In 1890 a new bishop, Dr Weber of Breslau, was consecrated in place of Dr Reinkens, who died in January of that year. The Jansenist Archbishop of Utrecht still co-operates with them; but the communion is nowhere growing in numbers or influence. In the movement of principles for reforms in general, by Père Loysen came to little; see HYACINTHE.

See DÖLLINGER; Miss Searle's Story of the Old Catholic and Kindred Movements (1883); an article in the Church Quarterly, vol. xiv. (1884—85); 'Döllinger and the Papacy,' in the Quarterly Journal (Eng. ed.) (1850); German works on Old Catholicism by Forster (1879), Bühler (1880), Bayer's (1882), and Reinkens (1882).

Oldenbarneveldt. See Barneveldt.

Oldenburg, a grand-duchy of northern Germany, consisting of three distinct and widely separated territories—viz. Oldenburg Proper, the principality of Liibeck, and the principality of Birkenfeld. Total area, 2508 sq. m. (less than Devonshire); pop. (1890) 364,909. Oldenburg Proper, which comprises this of the area, is bounded by the Ocean on three sides and the Elbe on the other. The principal rivers are the Weser, the Jade, and the Haage, Vehne, and other tributaries of the Ems. The country is flat, belonging to the great sandy plain of northern Germany, and consists for the most part of moors, heaths, marsh or fens, and sands. The chief occupation is agriculture, with some iron-working, fisheries, and shipping; there is also a little wool-spinning and linen-weaving. The principality of Liibeck, consisting of the secularised territories of the former bishopric of Liibeck, comprises the town of Liibeck and the county (north of which it lies), and is surrounded by the duchy of Holstein. Its area is about 200 sq. m. The principality of Birkenfeld (q.v.) lies among the Hundsruck Mountains, in the very south of Rhenish Prussia, by which it is surrounded; its area is 192 square miles.

Oldenburg is a constitutional ducal monarchy. The constitution, which is based upon that of 1849, revised in 1862, is common to the three provinces, which are governed by the same representative. Each principality has, however, its special provincial council. The grand-duke has a civil list of £12,570, besides private revenues.

Oldenburg became an independent state in 1150. The family that then established its power has continued to rule till the present day, giving, moreover, new dynasties to the kingdoms of Denmark, the empire of Russia, and the kingdom of Sweden. On the death, in 1667, of Count Anthony Gunther, the wisest and best of the Oldenburg line, his last son of the Stein-Gottorp branch of the family, Paul having given Oldenburg to his cousin, Frederick-Augustus, of the younger line of the House of Oldenburg, the emperor raised the united Oldenburg territories to the rank of a duchy. For a time the duchy was divided into the grand-duchy of Oldenburg, and the grand-duchy of Holstein. In 1866 Oldenburg and Holstein joined the German Confederation. The Liebke territories were added in 1863; Birkenfeld at the Congress of Vienna, when Oldenburg became a grand-duchy. The grand-ducal house is of the House of Oldenburg, in 1873, when by a family compact Christian VII. made over his Oldenburg territories to the Grand Duke Paul of Holstein, and by the marriage of the Prince Augustus, of the younger line of the House of Oldenburg, the emperor raised the united Oldenburg territories to the rank of a duchy. For a time the duchy was divided into the grand-duchy of Oldenburg, and the grand-duchy of Holstein. In 1866 Oldenburg and Holstein joined the German Confederation. The Liebke territories were added in 1863; Birkenfeld at the Congress of Vienna, when Oldenburg became a grand-duchy. The grand-ducal house is of the House of Oldenburg, and a dynasty now rules the state. The capital, Oldenburg, is pleasantly situated on the banks of the Hunte, 30 miles WNW. of Bremen by rail. It is the focus of the literary, scientific, and commercial activity of the duchy, and has a public library of 100,000 volumes, a picture-gallery, museum, &c. The grand-ducal palace is worthy of note for its fine gardens, its valuable pictures and other art collections, and its library. The principal church, St Lambert's, contains the burying-vaults of the reigning family. Oldenburg was the seat of an archbishopric, and is noted for its great castle and horse fairs. Pop. (1875) 15,701; (1890) 21,646. See Rüde's Oldenburgische Chronik (3d ed. 1863).

Oldenburg, Henry, a native of Bremen, born in 1626, was emmuli for his native city in London during the period of the Long Parliament and the protectorship of Cromwell. Being a being tutor to Lord Henry O'Brien and Lord John, the English, he was elected one of the very first members of the Royal Society, and, as assistant-secretary, edited its Transactions from 1664 to 1677, maintaining an extensive correspondence with Spinoza, Leibnitz, Bayle, and many other learned men of the age. Milton also knew him, and addressed him in the Epitola Familiae. Oldenburg died at Charlton, near Greenwich, in August 1678.

Oldham, a parliamentary, municipal, and county borough of Lancashire, on the Medlock, 7 miles NE. of Manchester, 5 SSE. of Rochdale, and 38 ENE. of Liverpool. It has grown since 1700 from a small village, such growth being due to its proximity to the Lancashire coalfields, and to the marvellous extension of its cotton manufactures. It has nearly 300 mills, with more than 1 million spindles, which consume one-fifth of the total imports of cotton from abroad; and the other manufactures, which include silk (once a leading industry), cords, &c., besides huge weaving-machine works, one employing 7000 hands. The town-hall (1841) is a good Greek edifice, enlarged in 1870 at a cost of £23,000; and there

550
are the lyceum (1854–80), a school of science and art (1863), public baths (1854), an infirmary (1870–77), and the Alexandra Park of 72 acres (1863). Oldham received its charter of incorporation in 1849. It was enfranchised by the Reform Bill of 1832, and returns two members, the parlia-
mentary borough (which extends into Ashton-under-Lyne parish) covering 19 sq. m., the munici-
pal only 77. The first (1832–55) was the former (1855–82), who resigned. The first (1849–81) was the former (1882–1900), who resigned. The later (1861) was the former (1891) 1891, 3,313; (1881) 111,343; (1891) 130,463.

Oldhamia, a genus of fossils of unknown affinities met with in the Cambrian system. Old-
hamia assumes various forms, sometimes consisting of short radiating branches or umbels, which spring at regular intervals from a central thread-like axis; at others the branches radiate in all directions from a central point. Some pale-
ontologists have supposed the fossil to be a Ser-
tularian zoophyte; others have referred it to the
polyzoa; while yet others think it may be a sea-
weed. Possibly it is not a fossil at all, but merely an inorganic structure.

Oldhrov Beds. See Eocene System.

Oldmixon, William (1673–1742), author of dull histories of England, Scotland, Ireland, and America, and of works on logic and rhetoric, is known chiefly as one of the heroes of Pope's

Dunciad.

Old Mortality. See Paterson (Robert).

Old Point Comfort, a village and watering-place of Virginia, at the mouth of James River, on Hampton Roads, is the site of Fortress Monroe.

Old Red Sandstone and Devonian System, the name given to certain series of strata that are intermediate in age between the Silurian and Carboniferous. The former is commonly called the Devonian by the geologists, and the latter by the Carboniferous. The former is the most extensive period, and consists ofMesozoic and Palaeozoic rocks.

Old Red Sandstone.—This series, which underlies the Carboniferous system, was so called to distin-
guish it from another set of red sandstones which rests upon the Carboniferous strata, and was for-
merly known as the New Red Sandstone (see Permian, and Triassic). In the British Islands the Old Red Sandstone is confined to Scotland, Wales, and Ireland. In Scotland it comprises two groups of red sandstones in some areas being unconformable, and in others conformable, on the lower. The lower group attains a great thickness (20,000 feet as a maximum), and con-
ists of coarse red, gray, brown, and purplish and sometimes yellowish sandstones, gray flagstones, clays, and shales, coarse conglomerates, and local beds of limestone and coal. Associated with these strata are interbedded lavas (porphyrites, diabase, &c.) and tuffs, which in some regions (Stirlings, Ochils, Pentlands, Cheviots, Ayrshire, &c.) reach several thousand feet in thickness. The fossiliferous strata of the Old Red Sandstone are chiefly of fishes and crustaceans and bivalved molluscs, which are mostly lycopodioseous. In Lanark-
shire a thin bed of shale in the group has yielded a few Upper Silurian fossils. The upper group comprises red sandstones, clays, conglomerates, and coal beds, which rest unconformably upon the Lower group. In Arran the group contains a limestone which has yielded marine Carboniferous fossils. In some places this group passes upwards conformably into the Devonian, which is the lower member of the Carboniferous system.

In Wales the Old Red Sandstone appears to graduate downwards into the Upper Silurian, and to be likewise conformable with the overlying Carboniferous strata. In Ireland, as in Scotland, there appears to be an unconformity between the upper and lower groups of the series, the former passing upwards conformably into the Carboniferous, and the latter ("Glengariff Grits") gradu-
ating downwards into the Upper Silurian.

In Scotland the Old Red Sandstone strata are developed chiefly in the Lowlands, but here and there they rise to considerable elevations. They think the Palaeozoic strata of the southern

lands and the Highlands, and are probably more or less continuous underneath the overlying Carbon-
iferous strata throughout the whole breadth of central Scotland. Other wide areas occur in the lower basin of the Tweed, along the borders of the Moray Firth, in the Caithness, Orkney Islands, &c.

In Wales the Old Red Sandstone is well developed in the region watered by the Usk and the Wye. In Ireland it is met with chiefly in the west and south-west.

Devonian.—In Devon and Cornwall we meet with a very different series of strata occupying the

same stratigraphical position as the Old Red Sandstone. The Devonian strata pass up conformably

into the Carboniferous system, but the base of the series is not seen, so that the relation of the strata

to the Silurian is not known. The English Devonian strata probably do not exceed 100 or 120 feet in thickness. It consists of three groups (Lower, Middle, and Upper), the rocks being prin-

cipally gray and brown slates, brown, yellow, red, and purple sandstones, grits, conglomerates, calcareous slates, and limestones. The calcareous and conglomeratic strata are generally well charged with fossils of marine types, and are developed chiefly in the middle group.

Devonian rocks occupy wide areas at the surface on the Continent. They appear in the north of France, and extend from the Boulognes eastwards to within about 30 miles of London. In England and Scotland they extend over more than 7,000 miles, and crop up along the flanks of the Urals. But the areas exposed to view probably bear but a small proportion to those which lie buried underneath later formations. In central Europe the strata have the general aspect of the English Devonian, and contain relics of the same marine fauna. In Russia they the strata are remarkable for showing alternations of calcareous and arenaceous rocks—the former of which contain an assemblage of fossils of a Devonian facies, and the latter, which is of arenaceous, a fish fauna resembling that of the Scottich Old Red Sandstone. It may be noted that rudcnic rocks are here and there associated with the Devonian strata of central Europe. In North America both types of strata appear; the arenaceous (the occurring in Nova Scotia and New Brunswick) while the Devonian type is met with in the state of New York and the Appalachian region, and is largely developed in the Mississippi basin.

Life of the Period.—Fossilized moulds are not uncommon in the Devonian strata, but land-plants rarely occur. These latter, however, are met with now and again in the Old Red Sandstone, more especially in that of Nova Scotia and New Brunswick. The chief forms are tree-ferns and small herbaceous ferns, lycopods (lepidodendroids), great forests, and the most distant sigillarioids. The vegeta-
tion would thus appear to have been for the most part flowerless. Here and there, however, remains of large conifers have been detected. Among the lower forms of life that swarmed in the seas of the period were rugose and tabulate corals. Of the former the most common are Agelas, Austroclathria, Cystiphylum, Calcarea, &c., while the honeycomb corals (Favosites) are the most common of the tabu-
late forms. Echinoderms abounded, especially crin-
oids (Cupressocrinus, Cyathocrinus) and pentru-
OLD RED SANDSTONE
OLEANDER

ites. Trilobites, which formed so marked a feature in the life of the Silurian seas, were now reduced in number and variety—among the more notable forms being Planocon, Homalonotus, and Brontea. Some of the eurypterids (most of which are small) attached to the land, and reached a size of from 5 to 6 feet long. They occur chiefly in the Old Red Sandstone. From the same strata in North America have come the remains of insects—neuropteroi and orthopteroi wings of ancestral forms of May-fly, &c. Myriopods also have been recognised; and some have been considered as Devonian fossils; indeed this group appears to have reached its maximum development in the seas of that period. Very characteristic forms are Unicites, Stringocephalus, and Reeserella. Lamellibranchs were well represented, some of the notable genera being Pterinea, Megadodon, Cucullaea, Aevia, &c. The marine gastropods call for no particular mention, for they belong chiefly to types which had come down from earlier Palaeozoic times. One may note, however, that the earliest pulmonates (snails) were found in the Old Red Sandstone. The straight Orthocera and other old genera of cephalopods continued to flourish, but coiled forms (Clymenia, Goniatites) began to predominate in Devonian times. From the Old Red Sandstone chiefly come the remains of numerous ganoi fishes—a group of primitive bony fishes. Among these are the placogonioids Cephalaspis, Pterygoplichthys, and Coccosteus, and the lepidogonioids Osteolepis, Diplolepis, Holoptilus, Echacoside, &c. The largest placognoiid was the Dinichthys of North America—the armchair of the age which was 10 or 15 feet in length. According to Dr Newberry, this fish was probably not less than 15 feet long, 'encased in armour, and provided with formidable jaws, which would have served the body of a man as easily as he bites off a radish.' Other forms (such as Diploperichas, and possibly Phaneropleuron) appear to have relations with the modern mud-tilich (Ceratodus) of Australia.

It is obvious that in the Old Red Sandstone and Devonian we have two distinct types of sedimentation, one representing the Red Sandstone under different physical conditions. The Devonian strata are unquestionably of marine origin, while the Old Red Sandstone beds are believed to have been deposited in large lakes or inland seas. Hence we meet with the latter in a few or more or less isolated basins, while the former extend over enormous regions of the earth. From the geographical distribution of the marine Devonian in Europe we gather that during the period in question the sea covered the south of England and the north-east of France, whence it extended eastwards, occupying the major portion of central Europe, and sweeping north-east through Russia, and how much farther we cannot tell. North of that sea stretched a wide land surface, in the hollows of which lay great lakes and inland seas, which seem now and again to have communicated with the ocean. It was in these broad sheets of water that the Old Red Sandstone seas were accumulated. Several of these old lakes in Scotland were traversed by lines of volcanoes, the relics of which are seen in many of the hill-ranges of the central and southern regions of that country. Volcanic action also at the same time manifested itself in the Old Red Sandstone seas in many smaller and even apparently in the Scottish area. The land, as we have seen, was clothed for the most part with a monotonous flowerless vegetation, but large pines grew on the higher and drier uplands, whence they descended to the lakes and seas. Very little is known of the terrestrial animal life of the period; most of the fossils met with in the lacustrine sediments of the period consisting of the remarkable ganoi and eury-

piders already referred to. These (the fishes especially) appear to have abounded in the lakes, whence, however, they now and again descended by the rivers to the sea. The general facies and the geographical distribution of the life of the Devonian and Old Red Sandstone are suggestive of genial climatic conditions. Some geologists, how-

ever, have thought that the coarse breccias and conglomerates which occur in the Old Red Sandstone may be indicative of somewhat cold conditions; for these deposits seem to have the aspect of morainic accumulations. It is possible, there-

fore, either that local glaciers may have existed in certain regions, or that the temperature may have been lowered for some time over wider areas. However that may be, the presence of the Devonian fauns in the Arctic regions seems to show that the temperature of the ocean must have been more equable in Devonian times than it is now.

Old Sarum. See Sarum.

Old Style. See Calendar.

Oldys, William, an industrious bibliographer, was a natural son of Dr Oldys, Chancellor of Lincoln, and was born in 1690. The most of his life he was spent in keeping up various publications of his own. He suffered by the South Sea Bubble, lost the property left by his father, and when he died (April 15, 1761) left hardly enough to decently bury him. For about ten years Oldys acted as librarian to the Earl of Oxford, whose valuable collection of MSS. he arranged and catalogued, and by the Duke of Norfolk he was appointed Norroy King-of-arms. His chief works are The British Librarian (1735, anonymously); a Life of Sir Walter Raleigh, prefixed to Raleigh's History of the World (1738); The Horatian Miscellany (8 vols., 1739), besides many miscellaneous literary and bibliographical articles.

Oleacea, a natural order of exogenous plants, consisting of trees and shrubs, with opposite leaves, and flowers in racemes or panicles. Nearly 150 species are known, mostly natives of temperate countries. Among them are the olive, lilac, privet, phyllethes, fringetree, &c. Between some of these there is a great dissimilarity, so that this order is apt to be regarded as a very heterogeneous group; but the real affinity of the species composing it is manifested by the fact that even those which seem most unlike are closely related, because of the line on the olive. Bitter, astringent, and tonic properties are prevalent in this order.

Oleander (Nerium), a genus of plants of the natural order Apocynaceae. The species are evergreen shrubs with leathery leaves, which are opposite or in threes; the flowers in false umbels, terminal or axillary. The Common Oleander (N. oleander), a native of the south of Europe, the north of Africa, and many of the warmer temperate parts of Asia, is frequently planted in temperate countries as an ornamental shrub, and is not uncommon in Britain as a window-plant. It was introduced into America by Linnaeus, who called it Rose Bay, and the French Rose Laurel (Laurier Rose). It attains a height of eight or ten feet. Its flowers give a splendid appearance to many mins in the south of Italy. It delights in moist situations, and is often planted in the garden. Its exhalations are injurious to those who remain long under their influence, particularly to those who sleep under it. A decoction of the leaves or bark is much used in
the south of France as a wash to cure cutaneous maladies. *N. odoratum*, an Indian species, has larger flowers, which are very fragrant. *N. piscidium* (or *Eschallot piscidium*), a perennial climber, a native of the Khasia Hills, has a very fibrous bark, the fibre of which is used in India as hemp. The beating of the stems in ponds kills fish.

Oleaster. See **OLEAGNUS**.

Ole Bull. See **BULL**.

Olelliant Gas, or Ethylene, C2H4, is the most abundant illuminating constituent in coal-gas. It may be obtained by the destructive distillation of coal, but more readily by the action of sulphuric acid on alcohol. It is a colourless gas with a faint colour, but little soluble in water or alcohol. It may be liquefied by cold and pressure. With air it forms a powerfully explosive mixture, which, on being burned, yields water and carbonic acid gas. When mixed with an equal volume of chlorine, and kept cool and in the dark, the two gases unite, with the production of drops of an oily liquid called Dutch Liquid (q.v.).

Olefines. See **HYDROCARBONS**.

Oleic Acid is one of the acids present in olive, almond, and other oils, in which it is united to glycerine. At temperatures above 57° (14° C.) it exists as a colourless limpid liquid, of an oily consistence, devoid of smell and taste, and (if it has not been exposed to air) exerting no action on vegetable colours. At 40° (44° C.) it solidifies into a firm, white, crystalline mass, and in this state it undergoes no change in the air; but when fluid it readily absorbs oxygen, becomes yellow and rancid, and exhibits a strong acid reaction with limnne paper. It is very difficult to obtain the acid in a state of purity, in consequence of the readiness with which it oxidises. It is obtained in a crude form, as a secondary product, in the manufacture of sperm candles; but when the pure acid is required, a lengthy process, starting with almond oil, must be adopted. Oleic acid forms normal (or neutral) and acid salts; but the first compounds of this class that require notice are the normal salts of the alkalies. These are all soluble, and by the evaporation of their aqueous solution form *soap*. Oleate of potash forms a soft soap, which is the chief ingredient in Naples soap; while oleate of soda is a hard soap, which enters largely into the composition of Marseilles soap. Of recent years a large number of oleates have come into use in medicine, which depend for their activity on the remarkable ease with which they are absorbed by the skin. Such are the oleates of zine, mercury, lead, tin, morphia, &c.; which, in this form, produce more rapid results than when applied as ointments.

Olein is a compound of oleic acid with glycerine, and constitutes the bulk of olive-oil. Along with it are associated stearin and palmitin, similar compounds of stearic and palmitic acids with glycerine. See **FATS**.

Olenus, a genus of Cambrian trilobites highly characteristic of the upper members of the system.

Oleograph. This is a name given to an ordinary chromo-lithograph which has been 'roughed' after printing, mounted on canvas, and varnished so as to imitate an oil-painting. See **LITHOGRAPHY**.

Oleomargarine. See **BUTTER**.

Oleometer, or Elaiometer, an areometer or balance for ascertaining the densities of fixed oils. It consists of a very delicate frame (state, the bulb being large in proportion to the stem, so weighted and graduated as to adapt it to the densities of the lading fixed oils. On the scale is marked the principal oils of commerce, with their specific gravity opposite. The standard temperature of the oleometer is 50° F. Those in general use are Gobby's and Lefebre's oleometers, Fisher's oil-balance, and Brix's areometer for lighter liquids.

Oléron (anc. *Uthur*), an island lying 2 to 10 miles off the west coast of France, and forming part of the department of Charente-Inférieure. It is 10 miles long by about 5 broad, and is unusually fertile. Pop. 17,799 mostly Protestants. On Oléron are the port of Le Château, and the small towns of St Peter d'Oléron and St Georges d'Oléron.

The Laws or Judgments of Oléron were a code of maritime law compiled at the instance of Eleanor of Guineue before she married Henry II. of England, modelled on the *Book of the Consulate of the Sea* (a maritime code regulating commerce in the Levant), but drawn from the decisions of the maritime court of Oléron, in the duchy of Guineue. It was intended for the use of mariners in the Atlantic waters, was introduced into England in the 15th century and continued in use in the 13th. The usages and decisions upon which it was based were those observed in the wine and oil trade between Guineue and the ports of England, Normandy, and Flanders. An English translation was published as *Rutter of the Sea*, by T. Petyt in 1536. See **INTERNATIONAL LAW**.

Olga, St., a saint of the Russian Church, wife of the Semnalianian (Varangian) Duke Igor of Kiev, who, after her husband's death (946), governed during the minority of her son, till 958. Thereafter she repaired to Constantinople, and was baptised, assuming the name of Helen. Returning to Kiev, she banished her father and then banished her husband and the chief meeting of the new creed. After her death (968) she was canonised, and is now held in high veneration in the Russian Church. Her festival is held on July 21.

Olibanum, a gum-resin which flows from incisions in several species of Boswellia, growing on large thick-leaved trees in the arid country, and is the mountains of Somaliland and the south of Arabia. These trees send their roots to a great depth into the crevices of the rock (see **BOSWELLA**; and an exhaustive memoir on this gum-resin by Sir George Birkwood, published in the *Linnean Transactions*, 1767, p. 111). She is known in the Hebrews, Libanos or Libanos of the Greeks, *Thos* of the Romans, of which all terms the ordinary English translation is Frankincense (q.v.). It
Olfant River. a forked stream of Cape Colony, rises in the mountains north-east of Cape-town, and, after a north-westerly course of 150 miles, enters the Transvaal, forming the base of the Transvaal basin, 15,000 sq. m. — Another stream bearing the same name rises in the Transvaal, and goes east to join the Limpopo.

Oligarchy (oligos, 'few,' and arché, 'I govern'), a term applied by Greek political writers to that perversion of an aristocracy in which the efforts of the dominating class were chiefly devoted to their own aggrandisement and the extension of their power and privileges. Thus it bears the same relation to aristocracy that despotism does to monarchy and ochlocracy to democracy.

Oligocene System. The British strata belonging to this system occur only in Hampshire, the Isle of Wight, and Devonshire. The series is as follows:

1. HEMPSWORTH BEES: fresh-water marl and clays overlaid by marine septarian clays. About 200 feet.
2. HEMPSWORTH BEES: marls and limestones; fresh-water below, marine above; about 400 feet.
3. OADBY BEES: fresh-water clays, marls, sands, and limestones. The lower division is of fresh- and brackish-water origin; the middle partly marine, partly fresh-water; the upper fresh-water. About 150 feet.

Oligocene strata, chiefly of fresh- and brackish-water origin, but containing intercalations of marine beds, overlie the Eocene of the Paris basin and that of Belgium. They likewise occur in Germany, where they form the oldest Territorial strata that have been detected in that region. The German Oligocene is mainly of fresh-water origin in its lower and upper portions, while marine deposits predominate in the middle of the series. It is noted for its beds of bituminous coal. In Switzerland the Oligocene attains a thickness of several thousand feet, chiefly conglomerates and sandstones, known as Molasse, and mostly of fresh-water origin; the basal portions, however, are marine and brackish-water. Other areas of fresh-water Oligocene more or less notable are met with in Alsace, Bresgavan, and Württemberg. In Anvergne, central France, lacustrine deposits of the same age are well developed. Of the oldest terrestrial plants, have yielded great numbers of organic remains.

Life of the Period. — The flora of Oligocene times was abundant and varied. Palm-trees (Saal, Flabellaria), both large and small, seem to have grown over all Europe. Amongst conifers were individuals (Pinus, Sequoia, Taxodium) and other forms, such as Glyptostrobus, like G. heterophyllus of Japan and China, and Widdringtonia, a genus now found only in South Africa and Madagascar. There were also proteaceous plants (Dryandra) of Australian affinities, and species of custard-apple (Annona), spindletree, maple, acacia, mimosa, lotus, annal, camphor-tree, cinnamon-tree, evergreen oak, laurel, &c., besides such familiar forms as birch, horn-beam, elder, elm, poplar, walnut, &c. Evergreens were the prevalent forms. The invertebrate fauna needs but little mention. American mastodons were volutes, cowries, olives, cones, spindleshells, &c. Cerithium was particularly plentiful in the estuaries of the period; while lamellibranches were well represented by modern types of marine and fresh-water habitats. Amongst the birds common in Europe, there were several species of geese, cranes, flamingoes, ibises, pelicans, eagles, secretary-birds, sand-grouse, &c. At the beginning of the period many mammals of extinct types lived in Europe, such as Palatherium and Anchitherium, survivals from the Eocene; extinct transoceanic forms of ungulates, such as Caintotherium (a small animal somewhat resembling the living cheiropteryx in outward appearance), Xiphodon (a slenderly, built deer-like animal), and Anoptherium (a long-tailed animal about the size of an ass, with two toes on each foot) of various kinds, and small rhinocerouses, Hyrnodon (a carnivore), also forms of squirrel, civet, marten, mole, musk-rat, &c.

Physical Conditions. — During Oligocene times a wide land surface appears to have extended over all the British area. In the region lying between the present coast of Scotland and the Line of the Firths of Forth and Firth of Clyde, there were many coal-bearing strata, which were subsequently silted over, and there preserved in the deposits of shallow lakes that dotted the surface of the volcanic country. It is probable that at this time there was land-connection between Europe and North America by way of the Faroe Islands and Iceland, in both of which occurs similar basaltic plateaux occur, containing intercalated layers of lignite, &c. like those of Antrim and the Western Islands of Scotland. The Oligocene strata of the south of England and the Franco-Belgian area are evidence that the sea or estuarine waters which occupied that region in Eocene times (see Eocene System) were gradually silted up. In Germany there existed great fresh-water lakes, fringed by wide marsh-lands and by dense forests of a subropical character. As the lakes became partially silted or dried up vegetation crept in and formed marshy or forested tracts. Some of these marshes were buried under fresh accumulations of sand and mud when the water had again risen. That these lakes were now and again in direct communication with the sea is shown by the occurrence of thick layers of marine origin intercalated amongst the fresh-water strata. In the Eocene of Switzerland, the lacustrine areas were entirely usurped by the sea, which may have entered them from submerged regions in the east of Europe. In Switzerland, in like manner, we have evidence of changing conditions. At first the sea covered a considerable
portion of the country, but eventually it disappeared, and its place was taken by a series of brackish-water lagoons and fresh-water lakes. The deposits accumulated in these lakes now form excellent deposits in the basin of the Alpes (Rigli-Rossberg). In central France, as in Germany, lacustrine conditions were characteristic of the period, one or more great lakes having occupied a considerable area in Auvergne. In southern Europe the Mediterranean had withdrawn from earlier regions which it had once flooded. By the Eocene times, but it still covered a more extensive area than at present. The climate of the Oligocene period was uniformly genial, but hardly so tropical as that of the preceding period. See Eocene System.

Oligoclase. See Felspar.

Olinda, a city of Brazil, 4 miles NE. of Pernambuco. Pop. 8160.

Oliphant, LAURENCE, traveller, novelist, and statesman, was born in 1829, son of Sir Anthony Oliphant, of Old Melville House, Edinburgh. Shortly after his birth, his family went to live in India, but he travelled with Jung Ithadur to Nepal, and after his return was admitted a member of the Scottish bar, and later of the English bar at Lincoln's Inn. His first work, A Journey to Khotanmut (1822), was followed by the Russian Journey (1828) and Narrative of Her Lordship's Mission to China and Japan in 1857-59 (1860). In 1861, while acting as Chargé d'Affaires in Japan, he was severely wounded by assassins, and consequently resigned his post. From 1855 to 1868 he sat in parliament for the Stirling burghs. Having become profoundly influenced by certain peculiar religious opinions, he renounced London society, joined for a time the community of T. L. Harris (q.v.) in the United States, and finally settled at Haifa (q.v.) in Palestine. He died at Twickenham, 25 December 1888. The religious opinions of his later life left no trace in the world, but he is remembered for his Minuscule and the Pict West (1855) and Scientific Religion (1888), as well as in his novel Masolam (1886), while they already formed the background of his earlier novel, Alltorn Peto (1883). Oliphant, when he subjected his intellect to occultism, brought a bright career to an untimely close by a rare literary endowment. His Piccadilly (1870) was a book of altogether exceptional promise, bright with wit, delicate irony, and, above all, individuality; but its promise was never fulfilled.

Other books of Oliphant's were The Transcaucasian Campaign under Omar Pasha (1856); Poteriæ and Filibusters (1600); The Land of Gilgal (1881); Traits and Travesties, Social and Politicall (1882); The Land of Khani (1882); Haifa (1887); and Episodes in a Life of Adventure (1887). See his Life by Mrs Oliphant.

Oliphant, MARGARET (née WILSON), one of the most distinguished of modern female novelists, was born in 1828 at Wallyford, near Musselburgh, Midlothian. In 1849 she published her first work, Passages in the Life of Margaret Maidalland, which instantly won attention and approval. Its most distinguishing characteristic was the unusual insight which regulates its exquisite delineation of Scottish life and character at once in their higher and lower levels. This work was followed by Caleb Field (1850), Merkland (1850), Adam Graeme (1852), Harry Mackenzie (1853), Magdalen Hepburn (1854), Lillicrap (1855), and Katie Stewart (1852), The Quiet Heart (1854), Zisdeke (1855), the last three of which originally appeared in succession in Blackwood's Magazine. Though these are of somewhat various merit, in all of them the peculiar talent of the writer is marked. They are rich in the minute detail which is clear to the woman's eye, and in the variety of insights into character, a flavour of quiet humour, and frequent traits of delicacy and pathos in the treatment of the gentler emotions. It was, however, by the Chronicles of Carlingford (first published in Blackwood's, 1861-64) that her reputation as a novelist was first secured. Among the first three, The Doctor's Family, the character of little Netty, the heroine, vivifies the whole work, and may rank as an original creation. The next in the series, Selina Chope, perhaps indicates a wider and more vigorous grasp than is to be found in any other of her works. Certain of the unlooker features of English dissent, as exhibited in a small provincial community, are here graphically sketched, and skilfully adapted to the purposes of fiction. After more than forty years of novel-writing Mrs Oliphant's powers showed no decadence; she retained in the last the same force and vigour as in the first, and there was still the same fidelity to truth in the minor details of her novels. A civil list pension of £100 was conferred upon her in 1868. She resided at Windsor for many years before her death, June 23, 1897.

Her other works include Agnes (1865); Madonna Mary (1866); Harriet (1869); The Brothers and Sisters of_Refuge (1870); Square Arden (1871); Omerta (1872); A Rose in June (1874); Thade Junior (1876); The Primrose Path (1878); Within the Precincts (1879); He that Walks in Darkness (1880); In Trust (1883); The Ladies Liddoves and It was a Loer and his Less (1883); Hotset, The Wizard's Son, and Sir Tom (1884); Madam and Two Stories of the Seen and Unseen (1886); House Divided (1887); and The Brothers and Sisters of Refuge and The Son of his Father (1887); The Second Son and Joyce (1888); Neighbours on the Green, Lady Cur, and A Poor Gentleman (1889); The Duke's Daughter and Kirsten (1896). Her more important contributions to general literature have been Life of Edward Irving (1862); Historical Sketch of the Reign of George II. (1860); St Francis of Assisi (1871); Memoir of the Comte de Montalembert (1872); The Makers of Florence (1876); Decro (1878); The Literary History of England, from 1700 to 1825 (1888); A Little Pilgrim in the Unseen (1882); The Makers of Youth (1888); Dante and Cervantes in Foreign Classics for English Readers (1888); Of Private Life in Public Men (1890); The Life of Lawrence Oliphant (1891); The Reign of Queen Anne (1894); The Makers of Modern Rome (1895); Jeanne d'Arc (1896); beside a child's history of Scotland (1897), and her Life of the publishing house of Blackwood (1897).

Olivarez, GASPARO DE GUZMAN, COUNT OF, Duke of San Lucar, was born January 6, 1587, at Rome, where his father was ambassador. He became the friend of Philip IV., his confidant in his amours, and afterwards his prime-minister, in which capacity he exercised almost unlimited power for twenty-two years. Olivarez showed ability for the government; but it failed him in his attempts to rob the people of their time-honoured privileges provoked insurrections in Catalonia and Andalusia, and ended the reconquista to drive the Spaniards from Portugal, and in 1640, but the continued ill-success of the arms of Spain at length thoroughly roused the nation, and the king was obliged to dismiss his favourite in 1643. He was ordered to retire to Tom (Zamora), and died there, 221 July 1645.

Saura, The Life of the Marquis du Condé d'Olivares (1673).

Olive (Olea), a genus of trees and shrubs of the natural order Oliveae, having opposite, evergreen, leathery leaves, which are generally entire, smooth, and minutely sealy. The general character of the
The genus is well illustrated by the accompanying cut. The species are widely distributed in the warmer temperate parts of the globe. The Common Olive (O. europaea), a native of Syria and other Asiatic countries, is in its wild state a thorny shrub or small tree, but through cultivation becomes a tree of 20 to 30 feet high, destitute of spines. It attains a prodigious age; some plantations, as those at Termini, in Italy, are supposed to have existed from the time of Pliny. Some trees in Turkey are credited with an age of 1200 years. There are two varieties of the common olive, one having narrow, willow-like leaves, gray green above and silvery below. In the other the leaves are similar in all respects, only much broader. The latter has also much the larger fruit of the two, but the oil it yields is rank and coarse to the palate, and is rarely used on the Continent out of Spain, in which country it is the variety chiefly cultivated. The narrow-leaved variety is preferred by the French and Italian olive-growers, the more bland and agreeable oil from which is better appreciated, especially by the British. Olive-oil may be said to form the cream and the butter of Spain and Italy, as it takes the place of those products of milk in the cookery and table uses of those countries. Being highly nutritious, it is also regarded as more wholesome than animal fats in warm climates. The finest quality of olive-oil is obtained from Tuscany. The oil is contained in the fleshy part of the fruit—not in the stone—from which it is extracted by pressure. The fruit when ripe is crushed to a paste. It is then put into wooden barrels and subjected to pressure moderately. Thus is obtained in considerable quantity the finest quality of oil, which is named 'Virgin Oil.' The pulp is then moistened with water and again pressed, the result being an oil of inferior quality, yet quite fit for table purposes. A further residue of oil is extracted from the pulp after it has been steeped in water; but it is only fit for soap-making and other manufacturing purposes (see OILS, and COTTON-SEED OIL). Unripe olives are pickled both for consumption in the countries in which they are grown and for exportation to other countries. The best pickled olives come from Genoa and Marseilles to England, but quantities are also imported from Languegeo, Leghorn, and Naples. They are eaten abroad before meals as a whet to the appetite, and in England at dessert with wine to restore the palate and as a digestive. Dried olives are also used for the same purposes, as well as pickled olives. The wood is much prized by cabinet-makers, being beautiful in color and grain, and capable of taking a fine polish; that of the root is most in demand for the making of snuff-boxes and ornaments.

The olive has been cultivated in the East from the remotest times, is associated with much mythical lore, and has been regarded in all ages as the bounteous gift of heaven, as the emblem of peace and plenty, and the highest reward that could be given to the honourable and the brave. The area devoted to olive-culture in Italy is stated at about 2½ million acres, and the total production of olive-oil is some 90 million gallons. The olive is also largely cultivated in Turkey and the Levant, in Morocco and Tripoli, as well as Spain; and some attention is being paid to its culture in South Australia. It grows luxuriantly in Chili, whither it was brought by the Spaniards. Jesuit missionaries introduced it into Mexico in the 17th century, and into California, where it grows freely. It has also been grown in Florida and other southern states. The culture of the olive has been attempted in England, but without success. Against south walls it lives, with slight protection in winter, in the neighbourhood of London, and there it produces fruit in exceptionally favourable seasons in Devonshire; but it is generally unsuited to the British climate. Even in those countries in which its culture may be profitably pursued the tree is somewhat fickle as to soil, aspect, and position. It does not succeed well in elevated situations, prefers sloping ground facing north and not far removed from the sea, and thrives best in calcareous soil. It is very generally propagated by suckers, but where great care is bestowed on itarching is practised. India is a most successful crop only once or twice in several years. There are other species of Olea more remarkable for the hardiness and usefulness of their timber than for their fruits. O. nervucao, O. capensis, and O. hartfordii, natives of the Cape of Good Hope, are small trees or shrubs with wood of such durability as to be used as timber by the colonists. The fruit of some of these is edible. The fruit of O. americana is also edible. The Fragrant Olive of Japan and China—O. (Osmanthura some) fragrans—is a handsome tree with fragrant flowers. It is a native of China and Japan, and is much esteemed amongst the Chinese for flavouring some kinds of tea. See A. T. Marvin, The Olive: its Culture in Theory and Practice (San Francisco, 1888); and United States Consular Report (1890).

Olive, Princess, the title assumed in 1820 by an impudent pretender, Mrs Olivia Serres, who claimed to have been born at Warwick on 26 April 1772, the grand-daughter of the Rev. Dr Wilmut, her mother being his only daughter, her father Henry Frederick, Duke of Cumberland, the youngest brother of George III. In 1791 she had married John Thomas Serres, painter, but had separated from him in 1808; and between 1805 and 1819 she had published ten trashy volumes of poetry and fiction. She resembled the royal family, and found some people ready to believe her to be really Princess of Cumberland and Duchess of Lancaster; but she died in 1834, at the age of 62, within the 'ranks' of the King's Bench, in November 1834. Latunia, the elder of two daughters by her husband (there seems to have been at least one son by someone else), married Anthony Thomas Ryves, the adopted son of William Combe ("Dr Syntax"), only, however, after ten years' separation. Her eldest daughter died two years after a jury, in Ryves and Ryves v. the Attorney-general, had decided that Olive Serres was not the legitimate daughter of the Duke of
Cumberland, and that eighty-two documents produced in evidence were forgeries.

See the Life of John Thomas Serres (1826); Notes and Queries, passim; and an article by E. Walford in the Gentleman's Magazine for August 1873.

Olivenite, a mineral, consisting chiefly of arsenic acid and protocoll of copper, with a little phosphoric acid, and a little oxide of copper. It is generally of some dark shade of green, sometimes brown or yellow. It is found along with different ores of copper in Cornwall and elsewhere. It is often crystallised in oblique four-sided prisms, of which the extremities are acutely bevelled, and the other lateral faces triangular or in angle, forming double four-sided pyramids; it is sometimes also spherical, kidney-shaped, columnar, or fibrous, which latter variety is known as wood-arsenate, and is greenish gray in colour.

Olivenza, a fortified town of Spain, near the Portuguese frontier, 20 miles SSW. of Badajoz. Pop. 7750.

Olivier, the comrade in arms of Roland (q.v.).

Olivet, Mount of, called also Mount Olivet, a region rising north and south on the east side of Jerusalem (q.v.), from which it is separated only by the narrow Valley of Jehoshaphat. It is called by the modern Arabs Jebel-al-Tor, and takes its familiar name from a magnificent grove of olive-trees which once stood on its western flank, but which has now in great part disappeared. The road to Mount Olivet is through St Stephen's Gate. Immediately beyond, at the foot of the bridge over the brook Kidron, lies the Garden of Gethsemane; and the road here parts into two branches, northwards to Galilee, and eastwards to Jericho. The ridge rises in three principal summits, that to the north being 361 feet above Jerusalem (2795 above the sea), the central summit, crowned with a village (Olivet proper), 286, and the third summit on the south 40 feet. David fled from Absalom by way of the Mount of Olives, which was also the scene of the idolatrous worship established by Solomon. The northern peak is the supposed scene of the appearance of the angels to the disciples after the resurrection, and is remarkable in Jewish history as the place on which Titus formed his encampment in the expedition against the fated city of Jerusalem. But it is around the central peak, which is the Mount of Olives properly so called, that all the most sacred associations of Christian history converge. On the summit stands the Church of the Ascension, on the site of a church built by St Helena; and near it are shown the various places where, according to tradition, our Lord went over Jerusalem, where the apostles composed the apostles' creed, where our Lord taught them the Lord's Prayer, &c. Near the Church of the Ascension is a mosque and the tomb of a Mohammedan saint.

Olivetans, a religious order of the Roman Catholic Church, was founded in 1313 by Giovanni Tolomei, a native of Sienna, and professor of Philosophy in the university of that city, who believed himself to have been miraculously cured of blindness. The order was confirmed by pope John XXII., and Tolomei was chosen the first general.

Olivine. See CHRYSOLITE, IGNEOUS ROCKS.

Olia Podrida (lit., 'potrid pot'), a Spanish national dish, consisting of flesh, fresh and salted, poultry, vegetables, &c., well seasoned with pepper and garlic, and steved together in a closed pot. The term is applied figuratively to literary productions of very miscellaneous contents. The French equivalent is pot-pourri, and the Scotch ketchup, both of which, but especially the former, are also employed in a figurative sense.

Ollendorf's System, a method of learning languages, invented by H. G. Ollendorf (1833-83), and designed for those who teach themselves. The grammars are meant to give the student a mastery of the essentials of the terms of the language, grammatical rules being few.

Ollivier, OLLIVIER ÉMILE, French statesman, was born at Marseilles on 21 July 1835, and, having studied law at Paris, began to practise as an advocate in that city. By clever pleading he established a reputation at the bar, and after 1864 acquired influence as a member of the Legislative Assembly. In 1865 the viceroy of Egypt appointed him to a high judicial office in that country. But he still took an active interest in French politics, and in January 1870 Napoleon III. charged him to form a constitutional ministry. But the real authority of the ministers was practically nil. Ollivier was an unsuspicious tool in the hands of the Imperialists. 'With a light heart' he rushed his country into the war with Germany, himself to be overthrown, after the first battles, on 9th August. He withdrew to Italy. Ollivier has written books on La Marine (1874) and Thiers (1879), and L'Eglise et l'État au Congrès de Vienne (2 vols. 1879), Principes et Conduite (1875), Nouveau Manuel de Droit Ecclésiastique Français (1883); and his L'Empire (vol. i. 1894) was an apology for his administration, and an attempt to throw the blame of the war wholly on Germany.

Olmütz, a fortress of Moravia, Austria, on the March, 236 miles NNE. of Vienna. Notable are the 14th-century cathedral (restored 1887); the church of St Maurice (1472), whose organ has 48 stops and 2342 pipes; the noble town-hall, with a steeply 255 feet high; the archiepiscopal palace; and the lofty Trinity column on the Obering. The former university (1581-1583) is reduced to a theological faculty, with over 200 students and a library of 75,000 volumes. The trade is more important than the manufactures. Pop. 20,176. Olmütz, which in 1610 was superseded by Brunn as the capital of Moravia, suffered severely in both the Seven Years' and the Seven Weeks' wars. Ferdinand I. signed his abdication here. See the local history by W. Müller (Vienna, 1882).

Olney, a pleasant little town of Buckinghamshire, on the Ouse, 11 miles W. by N. of Bedford and 10 SE. of Northampton. At the corner of the market-place still stands the house where Cowper (q.v.) lived from 1767 to 1780, writing with John Newton the Olney Hymns (1779). The place besides has memories of Scott the commentator, William Carey, and many more missionaries. Brewing and bootmaking are industries. Pop. 2347. See Thomas Wright's Town of Cowper (1806).

Olonetz, a government of Russia, bounded W. by Finland, N.E. by Altai, S.W. by Caucasian, and S. by Tobolsk. Area, 57,422 sq. m.; pop. (1883) 327,043. Forests cover 8.5 per cent. of the total area. Petrosavodsk is the centre of administration.

Oloron, a town in the French department of Basses-Pyrénées, on the Gave d'Oloron, 22 miles by rail from Pau. It has two interesting Romanesque churches. Pop. 7517.

Olshausen, HERMANN, theologian, was born at Oldolsheim in Holstein, 21st August 1796, studied at Kiel and at Berlin under Neander, and became professor at Berlin (1821), Königsberg (1827), and Erlangen (1834). He died 4th September 1839. His principal work was a complete commentary on the New Testament, completed by Eduard and
OLYMPIA

OLYMPIAD 601

Wissinger (1830 et seq.; Eng. trans. 4 vols. 1847-49; rev. ed. 6 vols. New York, 1856-58). His younger brother Justus (1800-92) was a distinguished Orientalist and linguist (1829-1901) and prominent part in the Sleswick-Holstein rising, 1848.

Olympia, the scene of the celebrated Olympic games, is a beautiful valley in Elis, in the Peloponnese, through which runs the river Alpheus. As a national sanctuary of the Greeks, Olympia contained within its small space, many of the choicest treasures of Greek art and a period of the most important states, such as temples, monuments, altars, theatre, and multitudes of images, statues, and votive offerings of brass and marble. In the time of the elder Pliny there still stood here about 300 statues. The Sacred Grove (called the Altis) of Olympia enclosed a level space about 600 feet long by nearly 580 broad, containing the sanctuaries connected with the games. It was finely wooded, and in its centre stood a chasm of caverns. The Altis was crossed from east to west by a road called the 'Ponpeia Way,' along which all the processions passed. The Alpheus bounded it on the south, the Claudens, a tributary of the Alpheus, on the west, and rocky but gently swelling hills on the north; westward it looked towards the Ionian Sea. The most celebrated building was the Olympiion itself, which belonged to the god Zeus. It was designed by the architect Libon of Elis in the 6th century B.C., but was not completed for more than a century. It contained a colossal statue of the god, the masterpiece of the sculptor Phidias, and many other splendid figures; its paintings were the work of Paeonius, a relative of Phidias. Next to the Olympiion ranked the Heraion, dedicated to Hera, the wife of Zeus and Queen of Heaven, containing the table on which were placed the garlands prepared for the victors in the games. The Pelopion, the Meteoron, the ten Theseions or Treasuries, built for the reception of the dedicatory offerings of the Greek cities, the temples of Eileithyia and Aphrodite also deserve mention. The Stadium, at which the contests took place, stood outside and east of the Altis; the Gymnasion and Palestra were also outside and dedicated first were carried on in 1875-81 by the German government at a total expense of £40,000, and threw much light on the plans of the buildings. Many valuable sculptures, bronzes, coins, and other objects were presented, and the Hermes of Praxiteles, a most beautiful and marvellous piece of sculpture. The results of these excavations have been published officially in Die Ausgrabungen zu Olympia (5 vols. 1875-81, with 118 plates).

Olympic games were the most splendid national festival of the ancient Greeks, and were celebrated every fifth year in honour of Zeus, the father of the gods, on the plain of Olympia. Their origin goes back far beyond 776 B.C., the year in which the origin of reckoning time by Olympiads (q.v.) began. With the foundation of the games became a truly national festival for the first time in that year. At first, it is conjectured, only Peloponnesians resorted to the Olympic games, but gradually the other Greek states were attracted to them, and the festival became Pan-Hellenic. Originally, and for a long time afterwards, the Greeks contended except those of pure Hellenic blood; but after the conquest of Greece by the Romans the latter sought and obtained this honour, and both Tiberius and Nero figure in the list of Roman victors. Women were on exception, the priestess of Demeter Clainyne—were allowed to appear, but they were present, on pain of being thrown headlong from the Typeon Rock. The games were held at the first full moon of the summer solstice, when first throughout Elis, and then throughout the rest of Greece, heralds proclaimed the cessation of all intestine hostilities; while the territory of Elis itself was cleared of enemy. The competitors were required to undergo a preliminary trial before a jury, for ten months in the gymnasia at Elis, and during the last of these months the gymnasia was almost as numerously attended as the games themselves. Much uncertainty prevails as to the manner in which the contests were distributed over the different days. Krause (Olympia) suggests the following order: On the first day the great initiatory sacrifices were offered, after which the competitors were properly classed and arranged by the judges, and the contests of the trumpeters took place; the second day was set apart for the boys who competed with each other in foot-races, wrestling, boxing, the pentathlon, the pankration, horse-races; the third and principal day was devoted to the contests of men in foot-races of different kinds (as, for example, the simple race, once over the course; the dianas, in which the competitors had to run the distance twice; and the doilichos, in which they had to run it seven or twelve times), wrestling, boxing, the pentathlon (in which one of the powers and skill of the combatants were exhibited), and the race of hoplites, or men in heavy arms, known as the diaulos. The pentathlon (contest of five games—viz. leaping, running, throwing the discus, throwing the spear, and wrestling), the chariot and horse races, and perhaps the contests of the heralds; the fifth day was set apart for processions, sacrifices, and banquet to the victors (Oiaphron). The victors were crowned with a garland of wild olive-twig cut from a sacred tree which grew in the Altis, and presented to the assembled people, each with a palm branch in his hand, while the heralds proclaimed his name, and that of his father and country. On his return home he was received with extraordinary distinction: songs were sung in his praise (14 of Pindar's extant lyrics are devoted to Olympiados); statues were erected to him, both in the Altis and in his native city; a place of honour was given him at all public spectacles; he was in general regarded as the greatest of all Greek athletes, and Athens was boarded at the expense of the state in the Prytaneeion. The regulation of the games belonged to the Eleusinians, from whom were chosen the helenonikai, or judges, at first two in number, but latterly ten; the victors, however, were all Athenians Huellenikai. Thespis first exhibited the games in 394 B.C. Theodosius II. ordered the buildings, which had suffered from the hands of the Romans and of various Byzantine Emperors, as they afterwards did from Goths and Slaves, to be burnt. Olympic games (including bicycle races) were in a fashion revived at Athens in 1896, the helenonikai being, however, from France, Germany, and elsewhere, as well as from Greek territories.

See Krause's Olympia (1838); Bötticher's Olympia (1882); Banmister's Dikaiowrê; Lalon and Monceaux, Restauration Olympique (1888); and Curtius and Adler, Olympia die Erscheinung, heilige Aufgaben der Athener (1889).

Olympia, capital of the state of Washington, on a peninsula at the south end of Puget Sound, some 65 miles from the Pacific Ocean, and 121 miles by rail N. of Portland, Oregon. The Des Chutes River, which enters the sound here, provides abundant water power for the saw mills, boot-factories, &c. Pop. (1900) 4082.

Olympiad, the name given to the period of four years that elapsed between two successive celebrations of the Olympic games, a mode of reckoning among the Greeks apparently first employed systematized in the 31 century B.C. It is used only by writers, and is never found on coins and very seldom on inscriptions. The first recorded Olympiad dates
from the 21st or 22d of July 776 B.C. and is frequently referred to as the Olympian of Corinthians; for historians, instead of referring to the olympiad by its number, frequently designate it by the name of the year or years in which the games belonging to that period. The first year of our present era (1 A.D.) corresponded to the last half of the fourth year of the 194th with the first half of the first year of the 196th olympiad. See Chronology.

Olympias, the wife of Philip II, king of Macedonia, and mother of Alexander the Great. She was the daughter of Neoptolemus I, king of Epirus. She was a woman of great vigour and capacity, but was passionate, jealous, and ambitious. When Philip married Cleopatra, niece of Attalus, she left Macedonia, and she was believed to have instigated his assassination by Pausanias (337 B.C.). On the accession of Alexander she returned to Macedonia, and brought about the murder of Cleopatra and her daughter. Alexander treated her with respect, but he never allowed her to meddle with his political schemes. After his death his successor, the great Alexander the Great, married her; and in 317, the pair defeated and put to death Philip Arrhidæus, the weak-minded step-brother and successor of Alexander, together with his wife Eurydice. Her cruelties soon alienated the minds of the people, whereupon Cassander besieged her in Pidna, and on its surrender put her to death, 316 B.C.

Olympiodorus, one of the latest of the Alexandrian Neoplatonists, flourished in the first half of the 6th century after Christ, during the reign of the Emperor Justinian. Regarding his life nothing is known. Of his writings we possess a Life of Plato, with commentaries or scholia on the Gorgias, Phædo, Phaedo, and Alcibiades I. In these he appears as an acute and vigorous thinker and as a man of great erudition. Another Olympiodorus, of the Peripatetic school, flourished in Alexandria in the 5th century B.C., and was the teacher of Proclus (q.v.). A third Olympiodorus, from Thebes in Egypt, wrote in Greek a history of the western empire from 407 to 425 A.D., abridged by Photius.

Olympus, the ancient name of several mountains or chains of mountains—e.g. in Mylas, Cyprus, Lycaea, Elia, Laconia, Aetolia, and one, the most famous of all, the Thessalian Olympus. Its eastern side, which fronts the sea, shows a line of vast precipices, cleft by ravines filled with forest trees. Oak, chestnut, beech, and plane trees are scattered along its base, and higher up grow forests of pine, as in the days of the old poets of Greece and Rome. Its highest peak is 9750 feet above the sea. It was regarded by the ancient Greeks as the chief abode of the gods, and the palace of Zeus was supposed to stand upon its broad summit. According to Greek legend it was formerly connected with Osea, but was separated from it by an earthquake, and is now called the Peneus through the narrow vale of Tempe to the sea. The philosophers afterwards transferred the abode of the gods to the planetary spheres.

Om is a Sanskrit word which, on account of the mystical notions that even at an early date of Hindu civilisation were connected with it, acquired many meanings in the development of Hindu religion. Its original sense is that of emphatic or solemn affirmation or assent. Later it became the auspicious word with which the spiritual teacher had to begin, and the pupil had to end, each lesson of his rendering of the Veda. And ultimately by equal force (Aum) it came to be regarded as an abbreviated method of naming the Hindu Trinity. In the Laotian form of Buddhism the 'formula of six syllables,' Om mani padme hum, which is variously interpreted, is the most solemn and sacred of invocations; is the first thing taught to Tibetan and Mongolian children, the last prayer rehearsed by the dying, and it is carved on rocks, flags, and praying-wheels, and is looked on as the essence of religion and wisdom, and the means of attaining eternal bliss.

Omaha (Gael. Oigh mhaig, 'seat of the chiefs'), the county town of Tyrone, on the Strule, 34 miles S. of Londonderry and 110 N.N.W. of Dublin. It grew under the actions of Protestant settlers. As it was the first of a fortress in the end of the 15th century, when it was forced to surrender to the English. It formed part of James I's 'Plantation' grants, and was strongly garrisoned by Monmouth. On its being evacuated by the troops of James II. in 1689 it was partially burned, and a second fire in 1743 completed its destruction. But it has been well rebuilt, and is now a neat and prosperous town. Pop. (1831) 4148; (1891) 4089.

Omaha, the chief city of Nebraska, the seat of justice of Douglas county, is on the right bank of the Missouri River, at the convergence of several important railways. It grew under the actions of Protestant settlers. As it was the first of a

Oman, the most eastern portion of Arabia, a strip of maritime territory, extending between the Strait of Ormuz and Ras-el-Had, and bounded on the S.W. by the deserts of the interior. At a distance of from 20 to 40 miles inland a chain of mountains runs parallel to the coast, reaching 6000 feet in Jebel Akhdar. There are some rich fertile tracts in this region, especially where water exists for irrigation. The coast is hot and not very healthy. This part of Arabia is under the rule of the sultan of Muscat (q.v.).

Omar. See Calip.

Omar Khayyám, the astrologer-poet of Persia, was born at Nishapur, the capital of Khurasan, around the middle of the 11th century, and took his falsahid or poetical name, 'Khayyám,' from his father's calling of tent-maker. He
was brought up under the great Sunni teacher, Imám Mnaslik, and formed a close friendship with two of his fellow-pupils, Nizam-ul-Mulk and Hassan-ji-Sabbah, of whom the one became viceroy of Sofía, Alp-Arslan, and the other founded the sect of the Assassins. Omar himself had an offer from his old friend of a place at court, but accepted instead a yearly pension of 1200 gold pieces. He, however, obeyed the summons of Malik, and during the latter's residence helped to reform the calendar. The result was the Jedáli en-—'a computation of time,' says Gibbon, 'which surpasses the Julian, and approaches the accuracy of the Gregorian style.' To appease the odium theologicum that he had roused against himself he is said to have made the pilgrimage to Mecca; and he died in 1122 at Nishapur, where the north wind, as he predicted, still scatters roses on his tomb.

Of some mathematical treatises by him in Arabic, one on algebra has been edited and translated by Wоеpe (Paris, 1831); and it was almost solely as a mathematician that he was known to the western world, until in 1859 Edward Fitzgerald (q. v.) published his 'translation' of seventy-five of his Rubáiyát or quatrains. The poet of Aesthetics, such was Omar Khayyám, through some mischance, left very few works of poetry and prose, and others read into it that Sufi mysticism with which, indeed, it was largely adulterated long after Omar's death. He was a true poet; yet his fate has been that of the man in the story who lost his shadow till 53 years afterwards grown to a great monument, through whom he perished. For Fitzgerald's translation is so infinitely finer than the original that the value of the latter is such mainly as attaches to Chaucer's or Shakespeare's prototypes.

There are editions of the Rubáiyát by Nicola (464 quatrains; París, 1867), Mobini Muhammad Sadik Ali (nearly 800 quatrains; Lucknow, 1878), and E. H. Whinfield (253 quatrains; Lond. 1883), who also translated them into very literal English verse (1882). A prose translation by Justin H. McCarthy (1889) has little to recommend it. See an article by Professor E. Cowell in the Calcutta Review (January 1894), and vol. ii. of Fitzgerald's Letters and Literary Remains (1889).

Omar Pasha, Turkish general, was born at Plaski, in Croatia, in 1806 (according to some accounts in 1800). His real name was Michael Lattass; he was educated for the Austrian army at the military school of Thurn, near Carlstadt. Having by a breach of discipline rendered himself liable to punishment, he fled to Bosnia, and, embracing Mohammmedanism, gained through his beautiful calligraphy the post of writing-master to Abdul-Medjid, the heir to the Ottoman throne. On his pupil's accession in 1839 Omar Pasha was raised to the rank of colonel, and in 1842 appointed military governor of the Lebanon. In 1843 he displayed considerable skill and energy in suppressing an insurrection in Albania, and following the Russian invasion in 1855, the invasion of the Danubian Principalities by the Russians in 1853 Omar Pasha collected an army of 60,000 men, and, crossing the Danube in presence of the enemy, intrenched himself at Kalocsa, where he held the Austrians for two months after they withdrew from the Principalities. Omar Pasha entered Bucharest in triumph in August 1854. On 9th February 1855 he embarked for the Crimea, and on the 17th of the same month repulsed with loss of 40,000 Russians who attacked him at Eupatoria. He was soon afterwards (October 3, 1855) sent to relieve Kars, but arrived too late. In September 1861 he was charged to pacify Bosnia and Herzegovina, which were again in insurrection. This being accomplished, he attacked the Montenegrins, captured Cetinje, and overran the country in 1862. He died 15th April 1871.

Ombre (through the Fr. from Span., hombre, 'man'), a game of cards borrowed from the Spaniards; one of the Hellenes, though sometimes by two and by five. The game is played with 40 cards (the eights, nines, and tens having been removed), and each player receives nine cards, three by three.

Ondurman. See Khaetoum, Mahdi.

O'Meara, Barry Edward, physician to Napoleon on one occasion, was born in 1786. He first served as surgeon in the army, but was dismissed the service in 1808 for a discreditable share in a duel at Messina. Later he entered the naval department, and was on board the Bellatrophe when Napoleon surrendered to Captain Maitland. He pleased the great exile, and accompanied him as his private physician to St Helen. He took part with Napoleon in his squabbles with the governor, Sir Hudson Lowe, and was imprisoned and compelled to resign his post in 1815. On his return to England he asserted in a letter to the Admiralty that Sir Hudson Lowe had insulted designs against his captive's life, and had attempted insidiously to corrupt himself. For this monstrous charge he was at once dismissed the service. His Napoleon in Exile (1822) made a great sensation, and is still valuable if read with caution. He died obscure in London, 31st June 1836.

Omelette (Fr. Omelette), an exquisite dish when exquisitely prepared, and like most good things perfectly simple. Break fresh eggs (not less than two or more than five) in a basin with a pinch of salt and pepper, beat for two seconds, pour into an omelet-pan in which butter (1 to 2 oz.) is boiling. Add the mixture set, fry till one side is brown, double over in half and serve immediately. Savoury omelets are made by adding to the eggs finely-minced herbs, ham, bacon, fish, or game. For sweet omelets use a little sugar instead of pepper in the mixture, and place a spoonful of preserved fruit on the omelet before folding over. The word is said, by Littre and by Skeat, to be derived from the Old French Alemelle (a thin flat plate), first corrupted to Amelette, then Omelette.

Omen (perhaps originally ormen, for omens; root, audio, 'I hear')-also PRODIGY (Lat. prodigium for prodigium, from prodico, names given I. the Romans to signs by which they foretold good or bad fortune was supposed to be indicated. The former applied particularly to signs received by the ear and spoken words; the latter, to phenomena and occurrences, such as monstrous births, the appearance of snakes, the striking of the foot against a stone, the breaking of a shooing, sneezing, and the like. It was supposed that evil indicated as approaching might be averted by various means, as by sacrifices, or by the utterance of certain magic formulas; or by an extempore felicity of interpretation, as when Cesar, having fallen upon the ground in landing in Africa, exclaimed: 'I take possession of thee, Africa.' Occasionally we read of a reckless disregard of omens; as, for example, when P. Claudius in the first Punic war caused the sacred chickens, which refused to leave their cages, by the Romans to break the omen. See AUGUSTUS, DIVINATION, and FOLKLORE.

OmmiaDES. See Calif.

Ommibuses, vehicles 'for all,' the well-known public conveyances. So long since as 1662, Blaise Pascal, the author of the Lettres Provinciales, assisted by some noblemen, obtained a patent from the French king for the privilege of running public coaches, containing six persons, each along certain stages between Paris and Bavay by land, for five sous per passenger. For two years the scheme proved a great success, but the death of Pascal and other causes occasioned its disuse. The first omnibus, built in Paris in 1820, was drawn by three horses, and soon became popular. Paris has also an excellent system of railways which convey in eight passengers inside; the English railways have recently followed this practice. In England at the beginning of the 19th century stage-coaches were used by business men to reach London from its suburbs. These were succeeded by the omnibuses which was introduced in London in July 1829, by Mr Shillibeer, formerly a coachmaker in Paris, and were drawn by three horses, conveying twenty-two persons inside. Smaller and more convenient buses were introduced in 1848, which conveyed twelve passengers inside and outside. Outside seats along the centre of the roof followed in 1857, and the vehicle was sub- sequently much improved upon by Mr Miller of Hammersmith. Large omnibuses are in use in Glasgow and Manchester and other large towns, and the three-horse omnibus was re-introduced in London on the route from Charing Cross to Portland Road. Many recent improvements have been made in the arrangement of seats outside facing forward, the greater accommodation of the interior, and the lightness of the vehicle. The London General Omnibus Company, founded in 1835, took over 250 omnibuses. In 1891 it had 800 omnibuses conveying 10,000 horses and 3000 men. Each bus runs about 12 miles daily. The company builds for their own use about 90 or 100 buses annually. The average weight of an omnibus is 30 cwt., and the cost about £150. The more recent London Canal Car Company, whose opposition to the older company has resulted in a great reduction of fares, runs 217 buses, and employs 2019 horses. The average charge per mile by bus is less than 1d.

Ommium, JACOB. See HIGGINS.

Onphacite (Gr. omphale, 'unripe grape'), a grass-green granular variety of the Pyroxenes (q.v.), one of the constituents of Eclogite (q.v.).

Onphale. See HERCULES.

Onski, chief town of the Russian province of Altamansk, stands at the confluence of the Om with the Irith, 1800 miles E. of Moscow. It was built in 1716 as a defence against the Kirghiz; but is now of no importance as a fortress. It is the seat of administration for the Steppe provinces of western Asia. It has a military academy, a Greek and a Catholic cathedral, a museum, governor's palace, &c., and a declining trade with the Kirghiz in cattle, hides, furs, and tea. Pop. (1887) 33,847; (1895) 54,750.

On. See HELIOPOLIS.

Onager. See Ass, BALISTA.

Onagra, ONAGARAE, or ONOTHER-AEAE, a natural order of exogenous plants, consisting chiefly of herbaceous plants, but including also a few with simple leaves and solitary or terminal flowers. There are about 450 known species, natives chiefly of temperate climates, among which are some much cultivated for the beauty of their flowers, particularly those of the genera Fuchsia, Gän5sera (Evening Primrose), Clarkia, and Goedelia. The British genera are Epilobium (Willowherb) and Circeis (Enchanter's Night-

Onion. A few species produce edible berries, and the roots of one or two are edible; but none are of economic importance. The root of Digitalis purpurea alternifolia, found in the marshes of Carolina, and called Bouquet's Root, is emetic. Some species of Jussia are used in dyeing in Brazil. The root of the onion, Allium cepa, or common onion, is the chief vegetable used by man. It is a biennial bulbous-rooted plant. The bulb is simple, and in the common variety is solitary, showing little tendency to produce lateral bulbs. The native country of the onion is shrubland in obscurity. It is supposed to be indigenous to India, whence it passed into Egypt, where it was cultivated 2000 years before the Christian era. It is believed that it was transmitted to Greece and Italy, and gradually spread over Europe, in most countries of which it has been cultivated from time immemorial. The onion contains a white acid volatile oil, holding sulphur in solution, albumen, uncrystallisable sugar and mucilage, phosphoric acid, both free and combined with lime, acetic acid, citrate of lime, and lignin. The acid qualities, while present in every part of the plant, are most concentrated in the bulb. When it is cultivated in warm countries the acidity decreases, while the saccharine qualities increase. The juice of the new tenderness of Spanish and Portuguese onions. So mild and sweet are these that the punjants of Spain and Portugal eat them raw with bread. Indeed, the onion forms a very important article of food with the poor of those countries. It is very nutritious and easily digested, yet does not agree with all stomachs when cooked otherwise than boiled. In boiling, the essential oil is dissipated and the onion thereby rendered more agreeable to delicate stomachs. The onion is stimulant, diuretic, expectorant, and rubefacient. The acid of the juice has the reputation of digesting fat in the haid. The sap of the bulb by fermentation is converted into vinegar, and with the addition of dregs of beer yields by distillation an alcoholic liquor. The pulp of roasted onion with olive-oil forms an excellent anodyne and excellent poutic to surpassing tumours. There are
Ontario, the easternmost and smallest (7240 sq. m.) of the five great lakes of North America, receives at its south-west corner the waters of the upper lakes by the Niagara River, and at its north-east corner it issues into the St. Lawrence. Its surface, subject to periodical variations (4 to 7 years) of about 24 feet, and which it is attempted to explain on the supposition of there being a subterranean river out of the lake, is 326½ feet below the surface of Lake Erie and 246½ feet above the ocean-level. Its mean depth is about 300, its maximum depth 738 feet. It is 190 miles long, 55 in its widest part, and over 500 in circumference. It has many thriving ports, of which the chief are Kingston, Cobourg, Port Hope, Toronto, and Hamilton on the Canadian shore, and Sackett's Harbor, Oswego, and Charlotte in the United States. It is connected with Lake Erie by the Welland Canal, with the Erie Canal and river Hudson by the Oswego Canal, and by the Rideau Canal with the Ottawa; and in 1890 a ship-railway (69 miles) was projected to connect this lake with Lake Huron. Lake Ontario is subject to violent storms, and it is probably owing chiefly to the constant agitation of its waters that it freezes only for a few miles from the shore. The shores are generally very flat, but the Bay of Quinte, near Kingston, a long, crooked arm of the lake, which stretches about 50 miles, possesses some peculiarities. One of these, on which Hamilton lies, is a large basin almost enclosed by a natural bank of sand, which forms a beautiful drive. See Crossmann's Chart (1882).

Ontario, the most populous and wealthy province of the Dominion of Canada, is bounded N. and E. by Labrador and Quebec, S.E., S., and S.W. by the United States, N. by St. James' Bay, and W. by Keewatin and Manitoba. Area, 222,000 sq. m.; pop. (1881) 1,923,258; (1891) 2,114,321. The province extends from about 74° 50' to 96° W. long. The surface is generally undulating, and there are no elevations of any considerable height. The Laurentian Hills run westward from the Thimensand Islands near Kingston, and extend north of Lake Simcoe, forming the coasts of Georgina Bay and Lake Huron. In the middle of the province the high land forms the ridge of the Great Lakes from those entering the Ottawa and the St. Lawrence. The principal rivers of Ontario are tributaries of the Ottawa, which forms part of its north-eastern boundary. The St. Lawrence forms the boundary of the eastern portion of the province. The river from Sacket's Harbor to the Bay of Quinte is bounded by the Great Lakes, among its smaller lakes are Simcoe, Nipissing, Nipigon, and many others. Ontario is largely an agricultural country, and its resources are very great. Immense crops are raised of all the products of a temperate climate, and in the south-west corner of the province Indian corn is a regular crop, and grapes, peaches, and tomatoes are grown and ripen in the open air. In addition to arable farming, stock-raising, dairy-farming, and fruit-growing are important industries. The richest deposits of petroleum are in the district below Sault Ste. Marie where deposits at Sault Ste. Marie and the Lake Charton are worked. There are also extensive iron deposits at Sudbury—probably the most extensive in the world. The petroleum-wells, in the south-west part of the province, are yielding immense and apparently inexhaustible supplies; the same may be said of the nickel deposits at Sudbury. The nickel deposits of Sudbury are very numerous, and are the most extensive in the world. It is largely owing to the favourable position which the province occupies with regard to water-power—although steam-power is established to a large extent, coal being obtained at

ONTARIO

OOSTERZEE

without difficulty by means of the lakes, from Pennsylvania, and also from Nova Scotia—the manufactures are numerous and abundant.

The principal manufactures are agricultural implements, iron and wooden ware, wagons and carriages, railway rolling-stock (including locomotives), cotton and woollens, leather, furniture, flax, ordinary ironware, paper, soap, wood-woven, &c. The most thickly populated part of Ontario more nearly resembles England than any of the other colonies. There is only one large city, Toronto, which contains nearly 200,000 inhabitants, but smaller cities and towns besides (44,000, Hamilton; 43,000, London 27,000, Kingston 17,000, Guelph 11,000, St. Catherine's 11,000, Brantford 13,000, St Thomas, Peterborough, Port Hope, Woodstock, Galt, Lindsay, Paris, and Port Arthur, are scattered all over the province, and are usually manufacturing or agricultural centres. The farms in these districts are well cultivated and fenced, with houses as a rule superior to those found in Great Britain. Ontario has a perfect network of railways (between 5000 and 6000 miles), which has proved of great advantage in the development of the manufacturing and agricultural resources; and in addition it is supplemented by the means of transport provided by the lakes and by the magnificent system of canals on the St Lawrence. The revenue of Ontario is about $3,500,000, made up of subsidies and contributions from the Dominion government, land and timber sales, licenses, stamps, &c. The expenditure is invariably under the revenue, and the finances of the province are in a thoroughly satisfactory condition.

The value of the imports in 1880 was $42,292,519, including $24,122,243 from the United States and $14,542,789 from Great Britain. The value of the exports in the same year was $30,336,958, of which $23,449,821 went to the United States and $3,729,174 to Great Britain. The exports in 1893 (manufactured goods, agricultural products, animals and their products, in short) had a value of $38,950,783, while the imports were valued at $48,243,786. The industries in 1891 produced goods to the value of $240,100,000.

The school system of Ontario is admirable, and is under the control of a minister of Education, who is always a member of the Provincial Cabinet. The schools are supported by a tax on property with state grants, and are free to all. Roman Catholics may, if they think proper, establish separate schools, and are then exempted from supporting the public schools, receiving a separate grant from government. The children attending the schools in 1897 were 403,212, out of a total school population of 611,212. There are many universities and colleges, and the facilities for higher education are quite equal to those provided for elementary purposes. The municipal system is one of the most perfect in the world, and holds a position which has been followed in many other countries. The public affairs are administered by a lieutenant-governor, an executive council of eight members, and a legislative assembly of 75 members elected every four years. In the Dominion parliament the province is represented by 24 members in the Senate, and 92 members in the House of Commons. In Ontario the Protestant religious bodies predominate; the Methodists are the most numerous, followed by the Presbyterians, then by the Church of England.

Ontario—Ontario was largely founded by the immigration of United Empire Loyalists from the United States. In 1872 it was made into a separate province and called Upper Canada in 1791 (see article CANADA). The two provinces were reunited in 1840, as the result of the disturbances in 1837 and 1838, and remained in that position until confederation in the year 1867, when the province received the name of Ontario.

Ontology. See Metaphysics, Philosophy.

Ons Probandi, i.e. the burden of proof, is often a difficult question in litigation; but as a rule the plaintiff who institutes the suit is bound to give proof of the allegations on which he relies.

Onyx, an agate formed of alternating white and black, or white and dark brown stripes of chaledony. More rarely a third colour of stripes occurs. The finest and most admirable, and usually most valued variety of carnelian, called sard or sarda. It is one of the rarest and most beautiful kinds of onyx, and is more valued than carnelian.

Oodeporr. See UDAIFER.

Oojin. See UJAJIN.

Ookip. See Cape Colony, Vol. II. p. 733.

Ookagen. See CANDLE-FISH.

Oolite (Gr., 'egg-stone'), a variety of limestone, composed of spherical granules of calcite carbonate, which have a concentric and often a fibrous radiating structure. In many cases these granules contain a nucleus or kernel of some foreign substance, such as a grain of sand, and the successive layers or encrusting coats of calcite carbonate have been formed. Granules of this nature are seen forming in the springs of Carshalb. A similar oolitic structure has been observed occasionally in the coral-rock forming the surface of modern coral-reefs—which seems to owe its origin to the movement to and fro of grains of coral sand in pools or sheltered places in which the water is highly saturated with carbonate of lime, derived from the decomposition of dead coral. The coarser varieties of oolite are termed Peastone or Pebble.

Oosternhout. A Dutch town in North Brabant, 6 miles N.E. of Breda, with sugar-factories, tanneries, breweries, potteries. Pop. (1898) 11,001.

Oosterzee, Jan Jakob van, theologian, was born in 1817 at Rotterdam, studied at Utrecht, was pastor at Foehr, and in 1862 became a theological professor at Utrecht, being the leader of the Evangelical school in Holland. He died 29th July 1882. He wrote many works, amongst them a Life of Christ, a Christology, a work on John's Gospel, an Apocalypse, and a large number of commentaries on Luke and the Pastoral Epistles. In London he published a Theology of the New Testament (1867; Eng. trans. 1870, 4th ed. 1882); Christian Dogmatics (1857; trans. 1854); Moses (trans. 1876); Practical Theology (trans. 1879).
Ootacamund, or Tutakamund, the chief town in the Neilgherry Hills (q.v.), the principal sanatorium of the Madras Presidency, and the summer headquarters of the governor of Madras.

The town is situated on a hill, which is surrounded by hills, 7228 feet above the sea, 330 miles from Madras city, and 24 from the nearest railway station on the Madras line. There are a public library (1858), the Lawrence Asylum (1838) for the children of British soldiers, and botanical gardens. The mean annual temperature is 58°F. The first house was built in 1821. Pop. 12,335.

Ooze, a term technically applied to some kinds of deposits found covering the bottom of the deeper parts of the sea. It is not only the depth of the water, but the distance from the land which determines the occurrence of ooze. As we pass from the shore out to sea we find a succession of deposits, shingle, sandy mud—ultimately derived from the land; but at a distance varying from 60 to 300 nautical miles from the shore, and at a depth of 2000 feet or more, lie the various oozes, which consist of the remains of numerous small organisms, but especially of the shells of Foraminifera. A whitish deposit, containing enormous numbers of Globigerina shells, which in dying have sunk from the surface, is very widely distributed till depths of about 2000 fathoms are approached. There the Globigerina ooze vanes away, and is replaced in the deeper regions by so-called 'red clay.' At the surface above there are of course here as elsewhere abundant Foraminifera which still doubtless sink, but the physical conditions of the great depths are such that their shells are dissolved in falling. But in certain of the deepest parts, e.g. at 3573 fathoms, the 'calcarcous' exploders are found in another kind of ooze, composed of the flint shells of Radiolarians. Besides this, in other regions the shells of Pteropods and Diatoms are abundant enough to form a characteristic ooze.

It is to be understood, however, that the various oozes (Globigerina, Radiolarian, Pteropod, Diatom, &c.) pass into one another, and that the names usually express simply the predominance of one or other kind of shell, and also that the colours—white, yellow, brown, and red—mainly denote the proportion in which the 'red clay' is present. The latter oozes are unstable to the oxides of iron and manganese, and is composed of disintegrated materials of volcanic origin, such as pumice, and also of meteoric dust. These, after being carried by winds and floated on ocean currents, sink and are distributed at the bottom. But as to the ooze in the strict sense, it ought also to be noted that the dead or dying organic material, which the rain of these organisms brings to the bottom, serves as the fundamental food-supply of deep-sea animals, while the shells not only accumulate as ooze, but aid in the elevation of submarine—volcano tops to the level at which coral can grow. Finally, the results of the ooze of incalculably distant ages are seen in the chalk cliffs often obviously composed of Foraminifera, or in such Radiolarian deposits as Barshoos Earth. See CHALK, DIATOMS, FORAMINIFERAC, GLOBULARIA, PTEROPOD, RADIOLIA, SEA, and the concluding volume of the CHALLENGER Reports by Murray and Renard.

Opalite, name given by petrologists to minute black, opaque, amorphous aggregates, grains, and patches of indeterminate mineral matter, which are seen in many igneous rocks when these are viewed in thin slices under the microscope. Opalite is probably in most cases hematite, limonite, magnetite, or other iron oxide, and is a product of the chemical alteration of one or other of the original mineral constituents of the rock in which it occurs.

Opal, or King-fish (Lamprois luna), a fish of the family Coryphaenidae or 'Dolphins,' order Acantophyrgii. The body is compressed laterally and deep, and is covered with small decalcious scales. The cleft of the mouth is narrow, and there are no teeth. The dorsal fin is single and has no spinous portion; the pectoral and ventral fins are teliform and of nearly equal length. The tail is forked. The lateral line has a strong curve behind the base of the tail, and is set at a right angle between the eye and the root of the tail. This fish is beautifully coloured; the back is bluish green; the sides violet, becoming red underneath; round or oval silvery spots are scattered all over the body; the fins and tail are deep scarlet. It is found only occasionally near shore. It prefers the deeper waters of the North Sea, being found off Norway, the British Isles, Iceland, Newfoundland, and especially near the Azores and Madeira. It is rare in the Mediterranean, and has not been recorded off Greenland or east of the North Cape in Norway. Specimens have been caught measuring 6 feet in length; one of 4 feet 5 inches weighed 140 lb. The flesh is red or yellowish in colour, and is excellent to eat. Its food, so far as is known, consists of cuttle-fish and other cephalopods. Other names applied to it are Sun-fish (a name also applied to Orthogonus and to the basking shark), because it comes to the surface of the water in calm weather, Sea-pert, Carf, and Jerusalem Haddock.

Opal, a mineral which differs from quartz in containing generally 3 to 10—in some cases only 1, in others as much as 21—per cent. of water, its only other essential constituent being silica, although a little alumina, oxide of iron, &c. is often present. The water is readily driven off on the application of heat, and some opals contain so small a proportion of water that they might be described simply as jelliform quartz. Not infrequently minute scales or plates of tridymite (a crystallised variety of silica) are present in opal. The latter is never found crystallised, and does not exhibit a crystaline structure like quartz. It has a conchoideal fracture, and is very easily broken. There are many varieties, which pass into one another, so that their respective limits can be defined, from which has arisen no little confusion of names. The finest kind is called Precious Opal or Noble Opal, and sometimes Oriental Opal. It is semi-transparent, and translucent, usually of a bluish or yellowish white colour, yellow by transmitted light, and exhibits a beautiful play of brilliant colours, owing to minute fissures which refract the light. It is much valued for setting in rings, brooches, &c., and is polished with a convex surface, never cut into facets, both because of its brittleness and because its play of colours is thus better shown. The ancient valued opals very highly. The Roman senator Senius preferred exile to giving up an opal to Mark Antony. This opal was still to be seen in the days of Pliny, who ascribesto it a value equal to more than £100,000 sterling. The
Imperial cabinet of Vienna contains the most celebrated opal now known to exist. It is 5 inches by 2 inches. The finest opals are almost all brought from Cervenitza, between Eperies and Kaschau, in Hungary, where they are found disseminated as alteration-products in trachyto tuff. They are mostly yellow, gold or even white; but opals if really beautiful, is worth four or five pounds; and the price increases very rapidly with increase of size. Precious opal is found also in Saxony, in South America, &c. When the colours are not equally diffused, but in detached spots, it is called Cat's eye. There are both blackish and greenish varieties, apparently tinged by oxide of iron, which occasionally exhibit very beautiful reflections, and is then much prized. Gir rasol (q.v.) and Catechol (q.v.) are varieties of opal. What lapislaries call Prine d'Opal is porphyry of the same opaceous rocks, containing many small amygdules of opal. It is cut into slabs, and made into boxes and other ornamental articles; the stone which contains the opals being often artificially blackened by boiling in oil, and afterwards exposing to a moderate heat.

As far as the opals are white, yellow, green, red, or brown, and does not exhibit any play of colour. It is not a rare mineral, and is chiefly found in veins and cavities or diffused (as an alteration-product) through the mass of various igneous rocks. Semi-opal is more opaque. Wood Opal is a peculiarity which exhibits the various effects of wood, the place of which has been taken by the siliceous mineral. Hydrite and Memilite are varieties of opal.

**Opera** (Ital. Opera in Musica, Dramma per la Musica) is a drama which is sung throughout to the accompaniment of a full orchestra. The variety of composition, or that of the operatic or scenic declamation, duet, trio, &c., concerted piece or instrumental interlude are used as the exigencies of the situation demand. The whole is usually introduced by an introduction, coroapet, or Overture (q.v.), and often one of the acts contains a ballet or pantomimic dance. It is a direct development from the discovery by the Florence Academy (see Music) of Monody or the musical expression of a single individuality by a single voice. As every country, every school since 1600 has felt the fascination of the art, and nearly every great composer has contributed to solve it, the operatic is a universal possession, and its range is almost as wide and varied as the history of music itself. Three schools may be distinguished. **Italian Opera** is marked by its spontaneity and melodious character, and even more by the honour of priority; **German Opera** is the product of greater genius than the other two schools can boast, but lacks the continuity which makes the French school so interesting to the student.

**Italian School.**—The experiments in scene-writing, which culminated at Florence in the first real opera, **Dafne** (1594), by Peri and Caccini, the more successful **Euridice** (1600), and the very advanced work of Monteverde. The new departure in music soon spread its influence beyond Florence to Venice, where Monteverde spent the last part of his life, and Verona, Naples, and Venice. Alessandro Scarlatti (1659-1725) took up the work and founded the Neapolitan or ‘beautiful’ school. Scarlatti, by the prominence he gave to melody, may be said to be the founder of Italian opera, which to this day is noted for so-called melody in contrast to the comparatively indifference to other as important qualities, such as harmony, orchestration, and dramatic unity. No Italian work of the 18th century has survived save **Cimarosa’s Il Matrimonio Segreto** (1792), which, very similar in style to Mozart’s greater works, has been overshadowed by these. The most famous modern Italian composer is Rossini, a brilliant vocal writer, whose charming **Barber of Seville** (1816) is a model of opera buffa, and whose serious opera, **William Tell** (1829), also keeps a place in the repertoire of the European stage. The operas of Handel, Bellini, Donizetti, and Ponchielli, and Verdi’s new operas, are still performed with great success. The veteran composer at the age of eighty-eight produced still another work, **Falstaff** (1891).

**German Opera.**—During the 17th and early part of the 18th century the opera in southern Germany was purely Italian. Dresden, where Hesse reigned supreme, and Vienna were the two centres. It was in Hamburg that the National school was founded by Keyser, who wrote (1664-1734) over 100 operas in which a high dramatic ideal is apparent. Gluck, though a German, belongs more to the school of French Grand Opera. The German opera is of its own, consisting of a symphony to the overture, and it is the only musical background in the opera that is always present. During the second half of the 18th century the German opera reached its highest point in the works of C. A. F. J. C. Bach, and J. J. F. von Weigand. Gluck himself contributed much to the foundation of his single opera **Fidelio** (produced 1805, rewritten 1814). The operas of Weber were deeply imbued with the romanticism of the early 19th century, and in **Der Freischutz** (1821) he uses the national folklore with immense effect. To this new school of the opera belongs among others the **Marseillaise** and **Spohr**, the beauty of whose music is buried, like Weber’s Euryanthe and Schubert’s Rousanne, under absurd libretti.

**Melodrama in opera** is an effective device which originated in Germany. The singer receives thereby importance in his part in an ordinary speaking voice accompanied by orchestral music, which seeks to convey the meaning of the situation and scene to the audience. Benda first used it (**Ariodante**, 1774), and Mozart, who heard it in 1778, was much impressed by its possibilities. The most successful of the grave-dancing scene in Beethoven’s Fidelio; **Weber in Der Freischutz** and Mendelssohn in **A Midsummer Night’s Dream** have also used it with happy effect.

The **French Grand Opera School** is extremely important, not only on account of its continuity and consolidation, but because the features that have distinguished it, such as its tendency to imitate the French style, and its characteristic tendency to imitate the French style, have been translated into opera in other countries to it as a centre. It was founded by the Florentine Lully, reformed by the German Gluck; and Italians like Cherubini, Spontini, Rossini, Belgians like Grétry, Germans like Mozart and Wagner have both learned from it and contributed to its various stages of development. Lully (born 1633) arrived in Paris a boy of thirteen in the train of the Chevalier de Guise, and by his diplomatic and social, no less than by his musical talents, he gradually pushed his way to the very summit of musical success, and lived in great favour with King Louis XIV. In 1672 he obtained a patent conferring the sole right of producing operas in Paris, and this monopoly he held till his death in 1687. Musical Paris was sharply divided between his followers and those of Rameau (1683-1764), who, when the arrival of the English public made them unite their ranks in opposition to the foreigners. The characteristic of this French school from its beginning was its attention to rhetoric and dramatic requirements. The treatment of recitative in particular has always been a feature since Lully’s time, and he it was also who invented the overture. Gluck arrived in Paris in
1774, and produced his Iphigénie en Aulide and Iphigénie en Tauride there; and the ideal expressed by Peri and Monteverde, embodied to a considerable extent in these (1607) of Rossini's, has at last found its goal in the music drama of Wagner. Cherubini's seriousness and nobility of style (Les Deux Journées, 1800), Méhul's fine ear for effect (Joseph, 1807), Spontini's monumentality of conception (Vestale, 1805), and Halévy's dramatic truthfulness (Judith, 1876) have been Gluck's banner, and the roll of French grand opera is brought to a glorious close with the name of Wagner's predecessor, Meyerbeer (Robert le Diable, 1831, Huguenot, 1836, Le Prophète, 1843). The new blood he brought with him from the other world—Germany and Italy invigorated it, and the time was ripe when the experiment of Rienzi was made in 1842. Other important contributions to grand opera were Auber's Masaniello (or Muette de Portici, 1828) and Rossini's Guillaume Tell (1829).

**Opera Comique (by no means comic opera)** is a title applied to all works which, on account of spoken dialogue, were not eligible for performance at the Grand Opéra. Grétry's Cœur de Lion (1784), Méhul's Joseph, Boieldieu's La Dame Blanche (1823), Hérold's Pré aux Clercs (1832), and Auber's Le Maçon, Le Diables de la Comédie (1843), are of the same kind. This Opera Comique, so purely French, had a large share in the development of the modern lyric opera, of which Gounod's Faust (1859), Thomas's Mignon (1871), and Bizet's Carmen (1875) are good examples.

The Bentz (prismatic) attained a very high pitch of development in Paris, where Delibes (1836-91) produced his charming Coppélia and Sylvia.

Comic opera proper (**Opera Buffa**) is represented in Italy by Rossini's Barbiere, Donizetti's Figaro, and Verdi's last great work, Falstaff (1893); in Germany by Flotow's Martha (1847), Nicolai's Merry Wives (1849); in France (Opéra Bouffe) by Offenbach's Orphée aux Enfers (1858), Grand-Duchesse (1867), &c., Lecocq's Madame Angot (1873), &c., and Mascagni's Scene d'Enfer (1891).

**Music Drama** is the ideal which Wagner has sought to embody in Tristan und Isolde (1865), Meistersinger (1864), and Verdi's last great work, Falstaff (1893); in Germany by Flotow's Martha (1847), Nicolai's Merry Wives (1849); in France (Opéra Bouffe) by Offenbach's Orphée aux Enfers (1858), Grand-Duchesse (1867), &c., Lecocq's Madame Angot (1873), &c., and Mascagni's Scene d'Enfer (1891). Rienzi (produced in Dresden in 1842) establishes his connection with the Grand Opera of Meyerbeer, and in the Flying Dutchman (1843), Tannhäuser (1843), and Lohengrin (1849) the growth of his method is distinctly seen, as well as his indebtedness to many predecessors, especially, in orchestration, to Berlioz. Wagner seeks to make the 'Art Work of the Future,' as he calls it, equally dependent on music, drama, and scenic art—the requirements of none being sacrificed to the demands of the other, but all contributing to one effect until the impossibility of separating in the minds of the audience of every opera, in the general impression of the mind after a performance of the whole, the different parts of the dramatic work (see Götterdämmerung). As such the ideal of such an English school of opera as the 'Masques' of Lawes and others had suggested (1613-72), but no one was ready to carry on the work after his early death in 1695 (aged thirty-seven). Dr Arne's Artaxerxes (1722), out of thirty-four operas, is one of the other English operas which call for mention. Italian opera became the fashion in London (Handel wrote forty-four, 1710-39), and England's attention has been divided between that school and the highly inesthetical and, from an operatic point of view, worthless form of Ballad Opera, founded by Dr Pepusch (Beggars' Opera, 1728), until looking towards the world of America, America sought the recognition for England among the European schools of opera.—English opera during this period ranged over all America, in 1750, in the shape of the Beggar's Opera, and Italian opera in 1825.

See Hogarth, Memoirs of the Opera (1851); H. Sutherland Edwards, Essays on Modern Opera (1881); D. Hanslick, Die Moderne Oper, in three parts (1888), the articles in Gravitz and other musical dictionaries on Opera, &c., and on Gluck, Mozart, Weber, Wagner, &c. in this work.

**Operaglass** (Fr. lorgnette), a double telescope, used for looking at objects that require to be clearly seen rather than greatly magnified, such as adjoining scenery and buildings, the performers at a theatre or opera, &c. The operaglass is short and light, and can be easily managed with one hand. Its small magnifying power (from two to three at the most), and the large amount of light admitted by the ample object-glass, enable it to present a bright and pleasant picture, so that the eye is not strained to look at it, and it does not cause any greater power, which generally show a highly-magnified but faint picture. It allows the use of both eyes, which gives to the spectator the double advantage, not possessed by single telescopes, of not requiring to keep one eye shut (a somewhat unnatural way of looking), &c. The objects stand out stereoscopically as in ordinary vision.

The operaglass is the same in principle as the telescope invented by Galileo. It consists of two lenses, an object-lens and an eye-lens. The object-lens is convex, and the eye-lens concave. They are placed nearly at the distance of the difference of their focal lengths from one another (see Telescope). The operaglass need not be set to a precise point, as is necessary with ordinary terrestrial telescopes, for the shortening or shortening of the instrument does not decide an effect on the divergent action of light; the change must always keep with the object at a certain distance is most easily looked at. The two telescopes of the operaglass are identical in construction, and are placed parallel to each other. The blending of the two images is easily effected by the eyes, as in ordinary vision. Operaglasses have now come into such demand that they form an important article of manufacture, of which Paris is the great seat. So largely and cheaply are they produced in Paris that it has nearly a monopoly of the trade. They may be had for 2s. 6d. to 26 2s. 6d. The cheapest operaglass is a simple lens; those of the better class have compound achromatic lenses. A very ordinary construction for a medium price is to have an achromatic object-lens, consisting of two lenses, and a single eye-lens. In the finest class of opera-glasses, which are called double field-glasses, double eye-lens and object-lenses are achromatic. Pissis's celebrated field-glasses (Ger. Feldstecher) have twelve lenses, each object-lens and eye-lens being composed of three separate lenses.

**Ophicleide** (Gr. ophis, 'serpent,' and kleis, 'key'), a brass bass wind-instrument, was developed from improvements on the Serpent (q.v.) about the beginning of the 19th century. It consists of a conical tube having a bell like that of
the horn, a cup mouthpiece, and usually eleven holes stopped by keys like the old Kent bugle. It has the usual harmonic (see Harmonics) open strings of all brass instruments, its fundamental, never used, being an octave lower. By means of its keys it has a range, including all the semitones, of a little over three octaves, and its music is written in the bass clef. Alto and double-bass ophicleides have also been made, but not much used. It is much to be regretted that an instrument of such a characteristically rich tone, and capable of intonation so accurate as the ophicleide, should be allowed to fall completely out of use, it being almost superseded by the simpler three-valved instruments of the Saxhorn (q.v.) type.

**Ophidina.** See Serpents.

**Ophiglossaceae,** a sub-order of Plicae or Ferns (q.v.), consisting of a few rather elegant little plants with erect or pendulous stem, which has a cavity instead of pith, leaves with netted veins, and the spore-cases (thecae) collected into a spike formed at the edges of an altered leaf, two-valved, and without any trace of an elastic ring. They are found in warm and temperate countries, but abounded most of all in the islands of tropical Asia. Several species are European, and two are British, the Botrychiun lunaria, or Moonwort (q.v.), and the Common Adder's-tongue (Ophiglossum vulgatum), which was at one time supposed to possess magical virtues, and was also used as a vulnerary, although it seems to possess only a mucilaginous quality—on account of which some of the other species have been employed in broths. It is a very common plant in England. Its abundance in some places much injuring pastures.

**Ophir,** a region, frequently mentioned in the Old Testament, from which the ships of Solomon, fitted out in the harbours of Edom, brought gold, precious stones, sandalwood, &c. The voyage occupied three years. To inch worms was fixed in the vessel. Ophir was situated in a much-disputed question. Arius Montanus fixed it on Pom, Raleigh on the Moluccas, and Calmet on Armenia. Probably, however, Ophir was either on the east coast of Africa about Sofala, or in Arabia, or in India, but in which of the three countries is doubtful. Milton (following Purchas), Huet, Bruce ('the Abyssinian'), the historian Robertson, Quatremère,

Mauch, &c. are in favour of Africa; Michaelis, Nielsahr (the traveller), Gesellin, Vincent, Winer, Fürst, Knobla, Forster, Crawford, Kubel, and Twistel (Schröder, dict. of the Bible), of Arabia; Vitringa, Lassen, Ritter, Berthelot, Fahlb, and Max-Müller, of India. Josephus, however, it should be said, placed Ophir in the peninsula of Malaya, and his opinion has been adopted by Tenent and Von Döer. For a complete discussion of the point see Ritter's *History of Ophir,* eighty pages of which are devoted to Ophir. According to Ritter, who accepts Lassen's view, Ophir was situated at the mouth of the Indus.

**Ophites** (Gr. *ophitès*, from *ophis*, 'a serpent'), a class of Gnostics, who, while they shared the general belief in dualism, the conflict of matter and spirit, the emanations, and the Demiurgos, were distinguished by giving a prominent place in their systems to the serpent. Some of their divisions were the Sethians, the Naaseni (Heb. נאש, "serpent") in Phrygia, and the Perata, who honoured the serpent which tempted Eve, as having introduced knowledge and revolt against the bondage of the children of the earth. Their writings were mainly to Irenaeus, Clement, Origen, and Hippolytus: the last also contains an account of two other Ophite systems, that of the Sethians and of Justinus. Already in his day the sect was fast dying out, although Theodoret mentions some of the books of the Ophites as still existing.

See Gnostics, and the books named there; also Lipsius in the Zeitschr. für Wissenschaft. Theol. (1864); Gruber, *Die Ophiten* (1864); and the Rabbi Dr Adolph Hönig's monograph, *Die Ophiten* (1889).

**Ophitic Structure,** name given by petrologists to a structure seen in various crystalline igneous rocks, in which large plates of a pyroxene are penetrated and divided, as it were, into small portions, by crystals of felspar. The separated portions of the pyroxene, however, are in crystalline continuity, since they all possess the same optical orientation.

**Ophiuroidea.** See Brittle-Stars.

**Ophthalmia** (derived from the Greek word *ophthalmos,* 'the eye') was originally and still is sometimes used to denote inflammation of the eye generally; but it is at the present time usually restricted to inflammations of the conjunctiva or mucous coat of the eye (*conjunctivitis*) and to two other diseases, blepharitis and *ophthalmia turdata,* and sympathetic inflammation or ophthalmia (see under *Eye*).

**Ophthalmoscope,** an instrument by which the interior of the eye can be examined. It was first invented in 1847 by Charles Babbage (q.v.); but, as unfortunately the ophthalmic surgeon to whom he showed it did not recognise its importance, he laid it aside without making it generally known; and its principle had to be rediscovered by Professor Helmholz, to whom belongs the credit of bringing it before the medical and scientific world in 1851.

The value of the instrument depends on the circumstance that by illuminating or examining an eye in the same direction its deeper parts can be rendered visible. All forms of ophthalmoscope are adaptations of this principle. The form now generally in use resembles more that of Babbage than that of Helmholz. It consists of a concave mirror fixed on a focus of 6 inches to 9 inches in diameter, with a small hole in the centre, and certain lenses to use with it, the most important of them a separate convex lens of 2 inches focus, and 1 to 4 inches in diameter. Examination is facilitated by dilating the pupil of the observed eye with a stimulant, and for a complete examination the 5th century is often indispensable. The person whose eye is to be examined is seated in a darkened room, with a
bright light—e.g. a good gas-burner—on a level with his eye by the side of his head. The observer sits opposite him, and placing the mirror close to his own eye, and about 18 inches from the eye to be examined, reflects the light upon the latter, while he looks at it through the hole. The pupil in the lens or the grave of Reynolds, AMELIA OPITZ, daughter of a Norwich physician, Dr Alderson, was born in 1769, and while very young wrote songs and tragedies, and was acquainted with Godwin, Mrs Inchbald, Mrs Siddons, and much of the literary society of the time, and collected suitably to Opitz in 1789. In 1801 her first novel, Father and Daughter, appeared; the following year, a volume of poems, Adeline Morebray and Simple Tales were her next works. On her husband's death she returned to Norwich, and published his lectures with a memoir prefixed. She wrote also Temper, Tales of Real Life, Valentine's Eve, Tales of the Heart, and Madeline. Having been long acquainted with the Gurneys, Mrs Opitz became a Quaker in 1825, and afterwards published Illustrations in Lying, Detection Displayed, and articles in periodicals, but not novels. She died 24 December 1833. See her Memoirs by Miss Brightwell (1854), and Miss Thackeray's Book of Sibyls (1833).

**Opitz, Martin**, German poet, born on 23 December 1697, at Bunzlau on the Bober, in Silesia, who for a century or more after his death was extravagantly praised and admired as the 'Swan of Silesia,' the 'Father and Regenerator of German poetry.' This inflated reputation he had earned by trundling to the princes of Germany, by writing adulatory poems in their honour, by praising third and fourth rate poets, whoever was his protegé; or, to put the affair in kind. As a Protestant, he worked and wrote for one Count Hannibal von Dohna, a cruel persecutor of the Protestants; but then Count Dohna helped him to get (1628) from the emperor a patent of nobility, and Ferdinand II. had with his imperial hand previously (1625) crowned him with the laurel crown of the poet—recognition of his talent that Opitz valued above all things. He was summoned (1622) by Bethlen Gabor, Prince of Transylvania, to fill the chair of Philosophy and Poetic Literature at Weissenburg; but at the year's end was so home-sick of the rule of the rude, martial people, and so famished through lack of the kind words of his friends, that he returned to Germany. Then he curried favour successively with the Duke of Liegnitz (1624), Count von Dohna (1626), and King Ladislaus of Poland (1634), who made him his secretary and historiographer of Poland. But fate was against him: in 1620 he had fled from Heidelberg to Holland to escape war and the plague; now in Danzig, where he was living, he caught the plague from a beggar, to whom he gave a coin in the street, and died 29th August 1639. The poems Opitz wrote are like his ordering of his life, calculated: they owe their origin to the understanding, have no imagination, and little feeling, and are cold, formal, pedantic. The fact is, Opitz, originally a schoolmaster, schoolmasterly poetry into lifeless verse, and dead verse into classical Poetry must, he propounded, in his most original work, **Buch von der tunclichen Posterei** (1624; new ed. 1876), teach and instruct as well as please. Hence his favourite pieces are purely didactic—Trostgedicht in Wartens Freude der Welt und Leben zu eden, Tugend und Vaterland in der Blume des Gemüt's, Vildgut oder vom wahren Glück, Wertheus, and others—such as the 'good boy' writes who wishes to please a pedantic master. Yet Opitz is entitled to the credit of having championed the use of his mother-tongue against Latin, and using it in serious verse. He also insisted upon the difference between the
ancient prosody of feet and quantity and the modern prosody of accent and rhyme, emphasizing the use of the last for descriptive poetry, and recommending the Alexandrine form of verse as that best suited to the genius of his native tongue. His works include translations from classic authors (Sophocles and Seneca, whom he puts on exactly the same rank as dramatists), the Dutchen Hein- 
sins and Grotius (whom he sets up as models of style), and from the Bible. Through the men who 
sore by him—the so-called first Silesian school— 
Opitz reigned for nearly a century as a sort of 
posthumous literary dictator, a worthy rival of 
Gottsched.

The best editions of his Gesammelte Schriften are 
those that appeared in his lifetime (1637, 1641). See 
Lives by Streihke (1856), Weinhold (1862), and Palm 
(1862), and critical works on the Buch der Portaes by 
Borinski (1883), Fritsche (1894), and Bergboffler (1888).

**Opiu**, one of the most valuable of medicines, 
is the dried juice of the unripe capsules of a species of 
Poppy (q.v.), Pappaver somniferum, of which 
several varieties are cultivated, the most usual in 
India, Persia, and China being apparently the 
variety album. The cultivation of the poppy for 
the sake of opium is carried on in many parts of 
India, although the chief district is a large 
tract on the Ganges, about 600 miles in length 
and 200 miles in breadth, which is divided into 
two agencies, that of Behar and that of Ben-
ares, the central factory of the former being at 
Patna, and that of the latter at Ghazipur. The 
poppies is also extensively cultivated for opium in 
the Asiatic provinces of Turkey, in Egypt, in 
Persia, and in China; and opium of fair quality is 
produced, although not to any considerable 
amount, in some parts of Europe, and even in 
Britain.

The poppy requires for its profitable cultivation 
a rich soil, and in India is generally sown in the 
neighbourhood of villages where manure can be 
easily obtained. The soil ought to be fine and 
loose when the seed is sown. The subsequent 
cultivation consists chiefly in thinning and weed-
ing. Irrigation is practised. Mild moist weather, 
with night-dews, is deemed most favourable 
during the time of the collection of the opium. Very dry 
weather diminishes the flow of the juice, and much 
rain is injurious. The opium poppy is cultivated 
for its seed or oil and other purposes besides the 
production of the drug itself, see Poppies, general.

Opium, as a commercial article, is of great 
importance, exceeding indeed that of any other 
drug in use. The cultivation of the opium poppy 
in British India forms a most extensive branch 
of agriculture, and the collection and preparation 
of the drug itself employs a large number of 
persons. The seed is sown in India in the 
beginning of November; it flowers in the end of 
of the collector. When this is full it is carried 
home and placed in a shallow open brass dish, 
with holes bored in the sides and bottom that 
the fluid may drain out; this watery fluid is very 
detrimental to the opium unless removed. It now requires 
daily attention, and has to be 
turned frequently, so that the air may dry it equally, until 
it acquires a tolerable 
consistency, which takes three 
or four weeks; it is then packed in small earthen jars, 
and there it remains until the fact that 
where the contents of each jar 
are turned out and carefully 
weighed, tested, valued, and 
credited to the cultivator.

The opium is then thrown 
into vast vats, which hold 
the accumulations of entire 
districts, and the mass being 
kneaded is again taken out 
and made into balls or cakes 
for the market. After being fully dried these balls 
are packed for sale in the market. Of the Indian 
opium there are several qualities, as Patna, Ben-
ares, Malwa, &c. The area under cultivation 
in India with the poppy varies from year to year; in 
some years the area in Bengal alone has been as 
high as 500,000 acres. Certain districts are per-
mitted to cultivate the plant, but the cultivators 
must obtain a license. Government purchases 
the opium at about 10s. a seer of 2 lb., and 
an acre yields from 10 to 15 seers of opium over and 
above the petals, capsules, and seed.

In Persia the drug is prepared at Isphahan, Shiraz, 
and Yazd; the latter is considered the best. The 
morphia in Persian opium is only 2 to 8 per cent., 
against 7 to 11 per cent. in Turkish opium. In 
Khurasan the cultivation of the poppy increased 
tenfold between 1875 and 1880. A quantity of opium 
for local consumption is prepared in the 
shape of sticks or cylinders. That destined for 
China is mixed with linseed-oil in the proportion 
of 6 or 7 lbs. to each chest; but that sent to 
London is pure. The exports of Persian opium, which 
in 1874 and 1875 were only 2000 chests, rose before 
1880 to 7700 chests. In Turkey the production is 
also large, 3000 chests are exported in a year.

For the relation of the opium trade to the 
revenue of British India, see INDIA, Vol. VI. p. 
115. There has been a good deal of controversial 
discussion carried on of late years as to the 
effects of opium-smoking (see below), and the 
abolition of the Indian trade is by many earnestly 
demanded. Those who support the present fea-
sal, system of India say it is on the whole better that 
the preparation and sale of Indian opium should 
be in the hands of the government as a monopoly, 
for if abandoned by them its culture and manu-
facture would be carried on in many other localities 
favourable to the growth of the poppy. Indeed 
its culture has been already tried in Australia, Africa, 
and parts of America. It should also be remembered 
that China itself produces opium largely; there is 
virtual permission and open connivance of all the 
local officials of the empire to the growth of the poppy 
over the length and breadth of the empire. Professedly 
forbidden, its culture is free to all. The local pro-
duction of opium is indeed believed to be as large 
as the foreign import, since the authorities prefer 
to quietly encourage the home-grown produce, so as 
to cut off the temptation and demand for the foreign. 
In south-western China the production of opium 
is stated to exceed 280,000 cwt., and it sells at 
two-thirds the price of the Indian.
In 1890 the annual revenue from opium in India was nearly £10,500,000, of which the excise opium (or that locally consumed) yielded £1,000,000, and the 'provision' or export opium the rest. In 1897 the net revenue from this source was only about £4,000,000. About 49,000 chests (of 140 lb.) are produced in the native states of Central India, Rajputana, and Baroda, which pay a transit duty for export from Bombay. The following figures (in cwts.) show the decline in the export, and the countries to which the Indian opium goes.

In 1890 the chest of Indian opium fetched £185; but it gradually dropped to £71, although rather better prices were obtained in 1889. It is sold mostly by public auction at Calcutta. To prevent speculation and to steady prices, the quantity to be sold during the year is duly notified in the previous year. The bulk of the Indian opium is sent to China. Persian opium, like the Chinese, has increased greatly in recent years, and, being cheaper than the Indian article, has begun to have a distinct effect upon the market. The foreign imports from India by no means represent the total trade in the drug. There is an immense internal consumption of what is known as 'excise opium,' averaging about 4500 chests yearly. This is retailed to the Indian consumer as a decoction, or in the form of two smoking mixtures, chandu and mandud.

The different grades of opium imported into China (added to the stock held in bond from the previous year) was in 1889 as follows, in pieces of about 1 cwt. each:

- Malwa: 8,200
- Patna: 2,105
- Benares: 1,257
- Persian: 3,414
- Turkey: 2,414

Total: 8,370 = 105,000 cwt.

The net imports into China were, in 1888, 82,012 pieces, and in 1889, 76,032 pieces. The illicit or local duty and the import duty amount to 110 taels per chest, or about £26. From 1830 to 1840 the imports of foreign opium into China amounted to 29,019 pieces, containing a very large number of alkali acids, 35,000 pieces. In 1860, when the trade was legalised, the imports reached 89,744; in 1870, 95,043; in 1880, 96,839; and in 1895 they fell to 83,900 pieces. The imports of opium into Great Britain average 600,000 to 700,000 lb. annually. This is chiefly re-exported—about 140,000 lb. to the United States, and over 200,000 lb. to South America and the West Indies. The United States imports nearly 600,000 lb. of crude opium, and from 45,000 to 75,000 lb. of opium prepared for smoking.

In Europe opium is mainly used for medical purposes, and large quantities of it undergo further manufacture, in order to separate from it the active principles morphine, narcotine, &c. In Great Britain the chief manufacture of these salts of opium is carried on in Edinburgh, where two firms manufacture them in immense quantity, supplying probably a fifth of the whole quantity manufactured.

Chemical Properties, &c.—All kinds of opium have a bitter, nauseating taste, and a peculiar narcotic, heavy odour. Chemically it is a gum resin of the most bitter, narcotic, meconic and other acids, and the ordinary constituents of a plant juice. Its exact composi-

...
When opium is used habitually a tolerance for it becomes established, and enormous doses may be necessary, with great advantage, to produce the effects of the small doses which are so dangerous. Probably no remedy has such wide and universal applications.

It must be given with great caution to young children, but many other factors, such as pain, habit, idiocy, etc., and various diseases influence its action and dosage.

Pneumonia, in one-half the deaths from poison which occur in the United Kingdom are due to opium or its preparations. When the effects of a large dose become fully developed the person lies in deep coma and in a state of complete insensibility. Respiration is slow, noisy, and stertorous, the pulse is contracted to a 'pin-point,' and insensible to light, the pulse is rapid and weak, or sometimes full and slow, the face and skin generally are pale and livid, and covered with cold perspiration. Constant stimulation may arouse the patient partially, but he always tends to relapse into stupor. Death is the result of exhaustion of the respiratory center in the brain, but may be due to apoplexy or collapse. Such are the usual symptoms, but many cases present peculiar features, such as convulsions, vomiting, diarrhoea, delirium, dilated pupils, and other anomalous symptoms. The post-mortem appearance is usually characteristic, but the cerebral blood-vessels are usually very full, and there may be effusion of serum into the ventricles. The smallest fatal dose recorded for an adult is four grains, but enormous quantities are often taken without serious symptoms. In infants vomiting occurs doses (1/4 grain) may prove fatal. Death may occur in about two hours or even less; few cases are prolonged beyond twenty-four hours.

The treatment consists in making the patient vomit, and in washing out the stomach with large quantities of water; lying on the state of insensibility excitement sometimes fail to act. Atropine is often given subcutaneously, while coffee or tea or caffeine may be also freely given. The patient may be further aroused by keeping him moving about supported by attendants, by cold cloths applied to the chest, and by electric stimulation. Any violence or measures which tend to exhaust the patient should be carefully avoided.

Opium-eating.—The habitual consumption of opium or any of its preparations by persons otherwise in good health is known as opium-eating, the opium habit, morphine habit, or morphinism. Opium, laudanum, chloroform, black drop, nepenthe, morphia, and other forms are all used. They are most commonly taken by the mouth, the subcutaneous injection of Morphia (q.v.) being almost entirely confined to the more cultured and educated classes. A habit of this kind may begin to relieve pain or sleeplessness, and one month's constant use is said to be sufficient in many cases to confirm the habit. The amount consumed by different individuals varies greatly. Of morphine most habitues take about three grains daily; opium about five grains. A few go much higher. De Quincey says that at one time of his life he consumed 6000 drops of laudanum daily, but his ration was very excessive. The immediate effects are a feeling of stimulation and well-being, but as soon as these have passed off there ensues a state of languid somnolence. A fresh dose is then taken. It is a craving brought on by indulgence, and is to be ranked with such habits as drinking, smoking, gambling, &c. Many persons indulge this craving during their whole life, and do their daily work well. Such persons do not, however, go to any great excess, although the craving is so marked as to make those who suffer in reality from well-developed symptoms of chronic opium poisoning. The typical opium-eater is lean and pale, with dull, glazed eyes; he suffers from chronic dyspepsia, from nervous irritability, and disturbances of the digestive system, from hallucinations, from sugar, and various other disorders are sometimes complained of. Chronic deprivation causes severe nervous disturbances and not seldom alarming collapse. For successful treatment of the opium craving the patient had better be removed from his own home and friends to some institution where he can be under strict and constant medical supervision. There is no evidence of opinion as to whether the opium should be abruptly or gradually withdrawn. Recovery is generally complete in a few weeks, but relapses into the habit are exceedingly apt to occur.

Opium-smoking.—The smoking of opium as a stimulant-narcotic is practised chiefly in China, India, Borneo, and the Far East. In China probably about 1 per cent. of the entire population smoke opium, but the habit is growing rapidly. In 1767 only about 200 chests of opium were imported, whereas during the past 100 years it has increased to about 25,000. A chest is usually carried, placed in a small cup at one end; this is ignited and the smoke inhaled, and then slowly exhaled through the nostrils. As a result, Easterners experience mental and physical excitement, followed by a pleasant sense of well-being and content, and then narcosis. Europeans, as a rule, are not affected by it to any appreciable extent. In the pipe the opium is destructively distilled, and chiefly the products of destructive distillation come over in the smoke—pyridine, collidine, and similar bases. There is probably scarcely a trace of morphine. The flavour of the smoke is mild and aromatic. In China and Singapore there are public smoking-houses, but it is also largely practised in private. It is reported that there are a million opium-smokers in the United States, especially in San Francisco and New York.

There is great difference of opinion regarding the harmfulness of the habit. Some authorities hold that in moderation it is not more hurtful than tobacco, while missionaries and others maintain that the habit is fraught with moral, social, and individual degradation. This seems to depend largely on the extent to which it is carried, and the question is probably on all fours with that of alcohol in this country. Many Chinese smoke opium all their lives in strict moderation without apparent harm, while others have excessive degrees of the habit. The Chinese government is not absolutely confirmed in its excessive use. The latter without doubt wreak their constitutions and suffer in much the same way as confirmed alcoholics do.

See the articles Laudanum, Morphia, Poison; the medical works on stimulants and narcotics. As to the harmfulness of the use of opium, see Calkin, Opium and its Harmful Effects (Philadelphia, 1876); W. H. Beecher, Opiates and Opium in America and China; a Study of its Prevalence and Effects (New York, 1882); the publications of the Society for the Suppression of the Opium Trade (founded by Rev. J. M. Gough and the Other State of the Opium Question, and W. H. Beecher, The Truth about Opium (1882, for the defence). The Report of the Indian Opium Commission (1885) indicated great diversities of opinion—many affirming it to be less harmful than alcohol; but by a majority advised against interference by government. For the Opium Wars, see CHINA.
Opodeldoc is a popular synonym for soap Liniment (q.v.). The origin of the term, which was apparently applied by Paracelsus to various forms of liniments or local applications, is not known. The ope is the same as the ope of opomax, against abscesses, doubtless derived from the Greek opos, 'juice.' See Notes and Queries, October 1888, p. 316.

Opo'panax, a gum-resin obtained in Persia, which comes to Europe at rare intervals. It has an unpleasant odour resembling bruised ivy leaves. Holmes suggests that it may be the produce of some Araalaceous plant, but nothing is known of its botanical origin. The ancient physicians attached great importance to it as an anti-syphilitic medicine; Hippocrates, Theophrastus, and Dioscorides have each left descriptions of it. The plant Opopanax chironium, from which it was supposed to be obtained, grows generally throughout southern Europe. The perfume known as opopanax is not derived from this gum-resin. There is a commercial opopanax, a kind of perfumed myrrh, obtained from a Balsamodendron, largely imported into Germany, where an essential oil is distilled from it.

Oporto (Port. o porto, 'the port'), the second city of Portugal, stands on the steep, rocky, right bank of the Tagus River above the eight bridges by which it reaches the sea 3 miles to the west. The houses, as they rise confusely from the river's edge, some painted in strong reds, blues, or greens, some left whitewashed, and the majority retaining the granite gray of the stones they are built with, make up a very strange and a beautiful panorama, and range as the city is by the encircling pine-covered mountains' (Oswald Crawford); and many of these houses stand embowered in the greenery of gardens. One of the crags overlooking the river is crowned with a Crystal Palace (1885), surrounded by gardens. Many of the former monasteries are still standing, though put to other uses: one is a citadel, another the exchange, with splendid marquetry of wood in floor and walls, a third barracks, and so on. There are seven principal churches, including the cathedral (built by Henry the Navigator, the pious and learned, c. 1433), with a twelve enormous arches; the old Gothic church of Celsafeita (originally founded in 559), and the Church dos Clerigos, with a tower 213 feet high. The English factory (1753), the bishop's palace, and the hospital of St. Antiony are the most noticeable amongst the secular buildings. A general physical and technical academy, with observatory, scientific collections, &c., a medical school, a fine art academy, a commercial museum, an industrial institution, a library (1796) of 200,000 vols, and 9400 MSS., and two picture-galleries. On the south side of the river, immediately opposite the Quay, and connected with it by a lofty bridge, is the suburb of Villa Nova de Gaia, with a pop. of 9126, and extensive wine-cellar.

The railway to Lisbon (209 miles) crosses the river a little higher up, on one of the finest (segment) arch bridges built; the arch spans a horizontal distance of 549 feet, and its centre is 203 feet above the river. Pop. (1878) 103,838; (1890) 132,856, who are chiefly engaged in the manufacture of cloth and silks, hats, porcelain, ribbons, tobacco, soap, and candles, in metal-casting, and in the refining of sugar, refining, and brick-making, and in commerce and shipping. Oporto is the principal place of export for Port Wine (q.v., and also Portugal). The remaining exports of moment are cattle, oranges, figs, wine, coal, cattle, wool, coal, and timber, amount to £1,800,000 annually.

Originally the Portus Calle of the Romans (whence Portugal), this city was the stronghold of the Christians in the north-west of the Iberian peninsula, often, from once changed hands between the 8th and the 12th centuries. The people are noted for their sturdy patriotism and liberal sentiments; in 1808 they were especially hostile to the French; they stoutly opposed the usurper Miguel (1828), who in revenge executed great numbers of its people, but without breaking their spirit, for they supported Pedro of Brazil, and withstood the besieging troops of Miguel thirteen months (1832-33). It was the scene of frequent republican riots in the 18th century. See O. Crawford in New Review (1889).

Opos'sum (Didelphys), a genus of Marsupials, having ten incisors in the upper jaw, and eight in the lower, one canine tooth on each side in each jaw, three compressed premolars, and four sharply-tuberculated molars on each side—fifty teeth in all; the tail generally very long, prehensile, and

Virginian Opos'sum (Didelphys virginiana). In part scaly; the feet plantigrade; five toes on each foot, their claws long and sharp; but the inner toe of the right foot converted into a thumb, destitute of a claw, and opposable to the other digits. The pouch, so characteristic of marsupials, is generally absent, sometimes rudimentary, rarely complete. The unwebbed feet and non-aquatic habits distinguish this genus from Chinchillae (q.v.), also belonging to the family Didelphide. The name opossum has also been applied to certain Australian forms, but is better restricted to the American opossums, which are the only marsupials found in America. They range from the United States to the Argentine Republic. There are altogether twenty-three distinct species, with a considerable range in size, varying from that of a large cat to that of a mouse. The best known is the Virginian Opossum (D. virginiana). Among the marsupials they are nearest allied to the Dasyurids, from which they are doubtfully separable; if it were not for their geographical range, they would undoubtedly be placed in the same family. Although there are now no opossums found anywhere but in America, they existed formerly in Europe, as is shown by their fossil remains. The opossums are all carnivorous, one species, the Crab-eating Opossum, feeding—as its name denotes—upon crabs; in order to capture its prey it frequents marshy places. It is a native of tropical America. Merian's Opossum (D. dorsigrum) is remarkable for the fact that it carries its young on its back, their tails being twined round the tail of the mother; many other species carry the young on the back; this is due in many cases to the fact already mentioned—that

hides, coal, and timber.
there is no pouch. The Virginia Opossum is a foe to poultry-yards in the United States; but it can put up with frogs if there is nothing better to be had. The opossums, like other marsupials, have a lowly organised brain; but they are remarkably cunning in robbing poultry-yards; on the other hand, their agility in walking upright into the simplest and most obvious trap is more in accord with their brain structure. Hunting the opossum with dogs by night is a favourite sport in the southern states, especially in autumn, when the body has a thick layer of fat all over its surface, and is neither shaken down or shot as it hangs by the tail. The expression 'playing possum' refers to the opossum's habit of feigning death when caught. At such times, though usually very timid, it will endure almost any amount of torture, and give no sign of its suffering.

OPOTECA, a sleepy town of 1000 inhabitants, in Honduras, about 15 miles N.W. of Comayagua, formerly famous for its great silver-mines.

Opperln, a town of Prussian Silisia, on the Oder, 51 miles S.E. of Breslau. Since 1816, when it was erected into a seat of government for Upper Silisia, it has been a county seat, and now has considerable trade with new edifices and with parks and gardens. Its church of St Adalbert was founded in 903; and there is an old castle on an island in the Oder. The manufactures include pottery, cigars, cement, beer, leather, &c.; and there is a considerable trade in grain and cattle.

Pop. (1873) 12,488; (1883) 15,075; (1900) 19,206. See Lidzkiowski's Geschichte der Stadt Opperln (1863).

Oppenheim, a town of Hesse-Darmstadt, on the left bank of the Rhine, 20 miles S.E. of Mainz by rail, with fine vineyards. On the site of the Roman castle of Banconica, Oppenheim became a free Hanse town, and was previously诸侯, especially in the Thirty Years' War. Pop. 3452.

Opportunists, in French politics, are those who, like Gambetta, Ferry, and others like-minded, oppose doctrinaire as well as extreme views, accommodate themselves in great measure to the circumstances of the hour, and aim only at what can be obtained in that hour.

Optical Illusion. An object appears large or small, near or distant, according as the rays from its opposite borders meeting at the eye form a large or a small angle: when the angle is large, the object is either large or near; when small, the object must be small or distant. Experience alone enables us to decide whether an object of large apparent size is on account of its real size, or of its proximity; and our decision is arrived at by a comparison of the object in position with other common objects, such as trees, houses, &c., which may chance to be near it, and of which we have by experience come to form a correct idea. The same is, of course, true of apparently small objects. But when all means for comparison are removed our judgment is at fault. Similarly, we erroneously infer spherical solids at a distance to be flat discs; and, by reason of Irradiation (q.v.) in the eye, the sun appears larger than it would if illuminated by a falter light, and a man in a white habit seems larger than he would if he wore a dark dress. Illusions are also produced by external causes; and instances of this sort are given under MIRAGE, REFLECTION, and REFRACTION.

The existence of impressions on the retina for about one-sixth of a second after the object which produced the impression has been removed produces another class of illusions. Common examples of this are the illuminated circle formed by the rapid revolution of an ignited carbon point, piece of red-hot iron, or other luminous body, and the fiery curve produced by a red-hot shot projected from a cannon.

Another form of illusion is produced to a person who is seated in a vehicle in motion; and it is very deceptive when the motion is so equable as not to be felt by the observer. The animal takes refuge in the tail, and is either shaken down or shot as it hangs by the tail. The expression 'playing possum' refers to the opossum's habit of feigning death when caught. At such times, though usually very timid, it will endure almost any amount of torture, and give no sign of its suffering.

OPTICS

Optic Nerve. See EYE.

Optics is the science of the phenomena of light. This science is usually divided into two classes: (1) Physical Optics, which treats of the nature of Light (q.v., as also MAGNETISM and UNDULATORY THEORY), and explains the phenomena of Colour, Reflection, Refraction, Interference and its consequences, such as the colours of thin plates and flus, Diffraction, Dispersion, and the geometrical representation and the properties of polarised light, for which see separate articles; and (2) Geometrical or Mathematical Optics. The leading idea in physical optics is to trace the progress of an undulatory or oscillatory disturbance in the Ether (q.v.); this disturbance, which may be represented as a wave-front. The direction along which this wave-front advances through a given point is a geometrical conception, which it is convenient to make use of in diaphragms, more convenient than it would be to draw a series of successive wave-fronts; in this direction of propagation through any given point is called a ray; and geometrical optics traces, by mathematical reasoning, the course of a given set of 'rays' under specified conditions, particularly under those which have reference to Reflection and Refraction (q.v.).

The pursuit of geometrical optics which deals with reflection of light is often called Catoptrics (based on such laws as that the angle of reflection is equal to the angle of incidence); that which deals with refraction is called Dioptrics; and for an account of these, reference is made to articles REFLECTION and REFRACTION respectively.

Though the Greeks and their disciples the Arabs had made some progress in mathematical optics, their knowledge was confined to the law of reflection and its more immediate consequences. Euclid, Aristotle, Archimedes, Hero, and Ptolomey were acquainted with the fact that light is transmitted to straight lines, but, with the important exception of Aristotle and some of his followers, the ancient philosophers believed that rays proceeded from the eye to the object, instead of in the contrary direction. Ptolomey was well acquainted with atmospheric refraction. Alhacen (1070) and Vitello the Pole (1290) were almost the only cultivators of this science during the middle ages, and their additions to it were unimportant. The lens, though known from early antiquity, was not applied as an aid to defective eyesight till after the time of Roger Bacon. Jansen, Metius, and other Dutchmen invented the telescope about the beginning of the 17th century; and the last-mentioned philosopher by his means made various important astronomical discoveries. Kepler, a short time after, gave the true theory of the telescope, explained the method of finding the focal length of lenses, and applied it to find the magnifying power of the telescope.
besides pointing out the mode of constructing an instrument better adapted for astronomical purposes than that of Galileo; he also made some use of his own telescope, and showed that images formed on the retina of the eye are inverted, a fact previously discovered by Maurolycus of Messina. From this the science of optics steadily advanced, and its treasury of facts received numerous additions through the labours of De Dominis, Snell (the discoverer of the law of refraction in 1621), Deserates, Fermat, Barrow, Mariotte, and Boyle. Up to the time of Newton it was generally believed that colour was produced by refraction, but that philosopher showed by a beautiful series of experiments that refraction only separates the colours already existing in white light. In his hands the theory and construction of the telescope underwent many valuable improvements, and in 1672 the description of his reflecting telescope was submitted to the Royal Society. Gregory had constructed an instrument on similar principles some years before. About the same time Grimaldi made his interesting series of experiments on the effects of diffraction, and noticed the remarkable fact of the interference of one pencil of light with the action of another. The theory of the rainbow, with an elegant analysis of the causes of the colour of the raindrops, and the general phenomena concerning the nature and propagation of light, now known as the corpuscular theory (see Light), completed Newton's contributions to the science. The important services of the ingenious but eccentric Hooke cannot be easily stated in a brief abstract, as he discovered a little of everything, completed nothing, and occupied himself to a large extent in combating faulty points in the theories of his contemporaries. It must not, however, be forgotten that he has as much right as Huygens to the credit of originating the theory that the deviation of refraction of Iceland spar was discovered (1669) by Bartholin, and fully explained in 1690 by Huygens, the propounder of the undulatory theory, who also aided the progress of mathematical optics to a considerable extent. The velocity of light was discovered by Huygens in 1675; by his own admission, the aberration of the fixed stars and its cause were made known by Bradley, who likewise determined with accuracy the amount of atmospheric refraction. Bouger, Porterfield, Euler, and Lambert rendered essential service to physical optics; the same was done by the mathematician Dollond (the inventor of the achromatic telescope), Clairaut, D'Alembert, Bowcovich, &c.; while in later times the experiments of Delaval on the colours produced by reflection and refraction; the discussion of the phenomena arising from unequal refraction or refraction carried on by Vince, Wallaston, Biot, Monge, and others; the discovery of polarisation of light by Malus (1808), and its investigation by Brewster, Biot, and Seebeck; of depolarisation by Arago (1811), and of the optical properties as connected with the Rights of the latter, the development of the undulatory theory and of optical science generally has been carried on in the present century by Lloyd, Airy, Cauchy, Clerk-Maxwell, Hertz, and others; and for an account of the present state of the scientific researches may be made to Mr. Theorell Peirce's Theory of Light (1890), in addition to the works mentioned under Light, and the articles Lenses, Microscope, Telescope, &c.

**Optimism** (Lat., optimus, 'best'), the doctrine that the existing order of things, whatever may be its seeming imperfections of detail, is nevertheless, as a whole, the most perfect or the best which could have been created, or which it is possible to conceive. Some of the advocates of optimism content themselves with maintaining the absolute position, that, although God was not by any means bound to create the most perfect order of things, yet the existing order is de facto the best; others contend that the perfection and wisdom of an Almighty God necessarily require that His creation should be the most perfect which it is possible to conceive. The philosophical discussions of which this controversy is the development are as old as philosophy itself, and are dealt with in the article on the origin of Evil (q.v.). But the full development of the optimistic theory as a system of thought was reserved for Leibnitz (q.v.), in his Theodicee, the main thesis of which is that, among all the systems which presented themselves to the infinite intelligence of God as possible, God selected and created in the existing universe the best and most perfect, physically as well as morally, regarding being as good as evil and the universe as a whole. The Theodicee was designed to meet the sceptical theories of Bayle, and its theories were ridiculed in Voltaire's Candide. Modern discussion on this question usually assumes the form of assertion or denial of the opposite doctrine of the *Prickly Pear*.

**Opuntia.** See Prickly Pear.

**Opus Operatum** (Lat., literally 'the work wrought') is the phrase employed in the Catholic theological schools to describe the manner of operation of the sacramental rites in the production of grace. It is intended to imply that the ministration of the rite (opus) is in itself, through the institution of Christ, an efficient cause of grace, and that, although its operation is not infallible, but requires and presupposes certain dispositions on the part of the recipient, yet these dispositions are but conditions sine qua non, and do not of themselves produce the grace. Hence, when the sacraments are administered to dying persons in a state of apparent insensibility, this is done in the hope and on the presumption that the dying person may, though seemingly unconscious, be nevertheless really disposed to receive the sacrament; but it is by no means held that if these dispositions be wanting the rite will still be efficacious. The phrase Opus Operatum is frequently used as denoting that the effect of a particular ministration or rite is primarily and directly due, not to the rite itself (opus), but to the dispositions of the recipient (operans). Thus the action of the Rosary, before a crucifix, of sprinkling one's self with holy water, of telling the prayers of the rosary upon blessed beads, the fervour and personal piety of the suppliant, and not the material object of the religious use, is held to be the efficient cause of the grace which is thereby imparted.

**Orache** (Arrhizus), a genus of plants of the natural order Cruciferae, having male and female flowers on the same plant. The species are numerous and widely spread over the maritime or saline parts of the earth, scarcely any species except the Common Orache (A. patula) being ever found inland or away from saline influence. Five species, including as Garden Orache (A. hortensis), are natives of Britain. Although formerly much cultivated in Britain, orache is now displaced as a pot-herb by spinach (Spinacea oleracea), a species of a closely allied genus. All the species have similar qualities and may be used in the same manner as spinach.

**Oracle**, the response delivered by a deity or supernatural being to a worshipper or inquirer; also the place where the response was delivered. These responses were supposed to be given by a certain divine fraternity, either through means of
mankind, as in the organs of the Pythia and the dreams of the worshipper in the temples; or by its effect on certain objects, as the tinkling of the cymbals at Dodona, the rustling of the sacred laurel, the murmuring of the streams; or by the actions of sacred animals, as exemplified in the Apis of Memphis, again in 1702, and the feasting on living chickens among the Romans. Such responses were, however, closely allied to augury, which differed in this respect, that auguries could be taken anywhere, while the oracular spots were defined and limited. Oracle dates from the highest antiquity, and gradually declines with the decline of Animism (q.v.), and with the increasing knowledge of mankind. Among the Egyptians all the temples were probably oracular. In the hieroglyphic texts the gods speak constantly in an oracular manner, and their consultation by the Pharaohs is occasionally mentioned.

In later days the most renowned of these oracles was that of Amun in the Oasis, where oracular responses were rendered either by the shaking of the statue of the god or by his appearance in a certain manner. Oracles were also used by the Hebrews, as in the consultation of the Urin and Thummim by the high-priest, and the unlawful use of Teraphims, and consultations of the gods of Phoenicia and Samaria. The Hebrew oracles were by word of mouth, as the speech of God to Moses, dreams, visions, and prophetic denunciations; besides which there were oracles in Phoenicia, as that of Beeshulum and others of the Baalim. They were also in use throughout Babylonia and Chaldea, where the responses were delivered by dreams given to the priests, who slept alone in the temples as counsellors of the gods. The most renowned of all Greek oracles was the Delphic oracle (see Delphi), which was held by all Greeks, open to all Greeks. Sacrifices were offered by the inquirers, who walked with laurel crowns on their heads, and delivered in questions inscribed on leaden tablets (of which many have been recently discovered); the response was deemed infallible, and was usually dictated by justice, sound sense, and reason. Other oracles of Apollo were at Apha in Phocis; at Ptoon, which was destroyed in the days of Alexander the Great; and at Iasmon, south of Thbes. In Asia Minor the most celebrated was that of Branchidae, close to Miletus, celebrated in Egypt by Tereus, and by the Persians, that of Dodona, Zeus had another at Olympia; and of various other deities existed elsewhere. A secondary class of oracles of heroic or prophetic persons existed in Greece, the two most celebrated of which were those of Amphiparrus and Trophonius. The first mentioned was one of the five great oracles in the days of Cressus, and was situated at Corfu in Attica. Those who consulted it forecast a whole day, abstained from wine, sacrificed a ram to Amphiparrus, and slept on the skin in the temple, where their destinies were revealed by dreams. That of Trophonius was at Lebade in Boeotia, and owed its origin to a seeded seer. It was given in a cave, into which the votary descended, bathed and anointed, holding a honeyed cake. There were some other oracles of minor importance. Besides these oracles, written ones existed of the prophecies of celebrated seers, as Baca and Musinas, which were collected by the Pindaristic, and kept in the Acropolis of Athens. Others of the Sibyls or prophetic women were popular, and at a later period (see Sibyl) Athenians and others dreamt in the day and slept. Amongst the oriental nations, as the Arabs and others, divination was and is extensively practised, but there are no set oracles. The Celtic Druids are said to have delivered responses, and the oracle of the Celtic god Belenus or Aelbio was celebrated. See Herodotus, Hist. v. 89, viii. 82; Curtius, iv. 7.

Hare, Ancient Greeks (1836); Bos, Antiquities of Greece (1825, p. 31); E. W. H. Myers, Greek Oracles (Heidelberg, pp. 425-492, 1880); Steigel, Griechische Sakralinterr- tuation (§§ 44-50, 1890); Schumann's work on Greek Antiquities (Religious Antiquities, French trans. by Galuski, 1857).

Oran (Arab. Waran), a seaport of Algeria, stands on the Gulf of Oran, 261 miles by rail W. by S. of Algiers and 130 by s. S. of Cartagena in Spain. It climbs up the foot of a hill, is defended by detached forts, has a thoroughly French appearance, having been mainly built since 1790, when the older Spanish town was destroyed by an earthquake, and possesses a Roman Catholic cathedral (1830), a grand mosque, a large military hospital, a college, a seminary, and two citadels or castles. The harbour is protected on the north and east by miles constructed in 1857 at a cost of £260,000; anf, iron ore, and cereals are the chief of the exports. Pop. (1891) 73,610. Oran was built by the Moors. During the second half of the 15th century it was a highly-prosperous commercial town, and was celebrated for its cloth and arms and fine public buildings. But it was taken by the Spaniards in 1560 and made a penal settlement. It was captured by the Turks in 1708, but retaken by the Spaniards in 1792. In 1790 it was destroyed by an earthquake, and shortly after was altogether abandoned by the Spaniards, the Turks occupying it again in 1792. The French took possession of the town in 1831.—The province of Oran has an area of 33,296 sq. m., and a pop. (1891) of 942,066, of whom 74,810 were French, 91,494 Spaniards, and 15,771 Jews; (1891) 942,066.

Orang, or ORANG-OUTANG (Simia antyrus), an anthropoid ape, found only in the forests of Sumatra and Borneo. There is only one species, though it has sometimes been said that another smaller variety occurs in Borneo. The orang is distinguished from other anthropoid apes by its reddish-brown colour; and it has been noticed that the colour corresponds to that of its human neighbours, just as the black colour of the chimpanzee and gorilla answers to that of the African tribes inhabiting the same country. Mikkulco-Maklay asserts that the Malays never use their words Orang utan ('man of the woods') for any ape, but for an uncultured tribe of Malays living in the woods.

Like other anthropoids the orang is arboreal in

Orang-outang (Simia antyrus)
habit, and can move with considerable swiftness through a forest, passing from tree to tree; on the ground it is awkward. It has a curious habit of breaking away the branches to a temporary but or near as it is usually called. The orang-utan was formerly regarded as of all manner of iniquities, such as carrying off women and children, and throttling people with its hind-foot as they passed under the trees. When these beliefs were proved false, it was transferred to the chimpanzee, and particularly to the gorilla. They were mainly dispelled by Wallace, who stated, however, of the orang that 'there is no animal in the jungle so strong as he;' but strength does not necessarily imply ferocity, and the orang seems to be a very tamable creature.

Hornaday, an American traveller, observed the orang in the act of making its nest. He thus describes the process: 'I got there just in time to see the orang build a large nest for himself. He took up a position in a fork which was well screened by the foliage, and began to break off small branches and pile them loosely in the crotch. There was no attempt at weaving, nor even regularity in anything. He reached out his long, hairy arm, snapped off the leafy branches with a practised hand, and laid them down with the broken ends and the pith with the tips. He worked with infinite dexterity, and standing there to weight it down, he turned slowly, breaking branches all the while and laying them across the pile in front of him until he had built quite a large nest. When he had finished he lay down upon it, and was so effectually concealed from us that I could not dislodge him, and after two or three shots I told the natives that they would have to cut down the tree.' During one day's travel in Borneo thirty-six old nests and six fresh ones were seen; there appears to be nothing like this habit-building, which has been stated by some to exist among the orang-utans.

The structure of the orang shows its near relationship to the other anthropoids and man. The curvature of the spine, which is an important character, appears, according to Cunningham, to be different from that of a full-grown man; but it corresponds to that of a boy of six years old. The extension of the cerebral hemispheres in the brain backwards over the cerebellum is about equal to what is found in the chimpanzee; naturally this is considerably less than in man, but greater than in the new-born chimpanzee. The orang-utan is nearest among the anthropoids to man in certain other characters, especially in brain characters; but, as the gorilla and chimpanzee show a nearer approximation in various other points, it would not be safe to call the orang the most man-like of apes. See Anthropoid Apes.

Orange (Lat. aurantium; from aurum, 'gold'), the name of one or more species of Citrus (q.v.), of which the fruit is much prized. Botanists generally regard all the oranges as of one species, Citrus aurantium, but some make the Sweet Orange, the Bitter Orange, the Bergamot Orange, &c. distinct species. The wild state of the orange is not certainly known, although its characters may be pretty confidently inferred from the degeneration of cultivated varieties; and no cultivated plant shows a greater liability to degenerate than the orange. The orange is always or nearly always worthless. From a remote antiquity it has been cultivated in India; and thence it seems to have spread into western Asia and Europe. It was then said to have been cultivated in China, and afterwards in the eastern parts of Asia. It has been alleged that the orange is a native of New Guinea, near the Gulf of Mexico; but the probable view seems to be that it has been introduced, and has become naturalized.

The Common Orange, or Sweet Orange (Citrus aurantium), is an evergreen tree of moderate size, with greenish-brown bark; the leaves oblong, acute, sometimes minutely serrated, the leaf-stalks more or less winged, the flowers white, the fruit roundish, the oil-cysts of the rind convex, the juice sweet and acid. It is cultivated in almost every part of the world of which the climate is warm enough, but succeeds best in the warmer temperate or subtropical climates, as in the south of Europe, where it is very extensively cultivated, as far north as the south of France. The orange does not seem to have been cultivated by the Greeks or Romans, but was probably brought to Europe by the Moors, and is supposed to have been introduced into Italy so recently as the 14th century, fully 1000 years after the citron. In the north of Italy oranges are sometimes grown in temporary conservatories, but often in the open air, except during winter, when they are covered with boards. In the southern part of England they are sometimes in like manner grown in the open air, with a shelter of boards or matting in winter, but trained against a south wall; they attain a large size, and yield good fruit. The abundant importation of the fruit, however, renders the cultivation of the orange in Britain unnecessary; and, in general, only small plants are to be seen in greenhouses or conservatories, as mere objects of interest. In some parts of Queensland and south-west Australia the orange is grown to great perfection, but its culture does not appear to be regarded as a profitable industry, probably owing to the absence of markets and the facilities of conveyance thereto. A few counties in the colony of New South Wales appear to be particularly well adapted to orange cultivation. A government report on the area under oranges gives it as 10,587 acres in 1889. Excellent oranges have been exported from the colony to Britain at remunerative rates. There are many varieties in cultivation, which are perpetuated by grafting upon seedling orange stocks and by layers. The principal orange-growing sections of the United States are Florida, Louisiana, and California.

Of the varieties of the sweet orange perhaps the most deserving of notice are the Portugal or Lisbon Orange, the most common of all, having the fruit generally round or nearly so, and a thick rind; the China Orange, said to have been brought by the Portuguese from China, and now much cultivated in the south of Europe, having a smooth thin rind and very abundant juice; the Maltese or Blood Orange, remarkable for the blood-red colour of its pulp; the Egg Orange, having fruit of an oval shape; the Mandarin Orange, or Clove Orange (C. nobilis), has fruit much broader than long, with a rind very loosely attached to the flesh, and small leaves; and the Tangerine Orange, apparently derived from the Mandarin. The St Michael's

Sweet Orange (Citrus aurantium), Branch in Flower: a, fruit; b, transverse section of same. (Bently and Trimen.)
Orange is a sub-variety of the China orange. The

and the Orange has now a great reputation. The Majorca Orange, the Seville, and the common-quat (C. japonica), from China and Japan, is little bigger than a gooseberry, and grows well in Australia.

The Bitter Orange, Seville Orange, or Bigarade (C. vulgaris, or C. bigaradia), is distinguished from the sweet orange by its more truly elliptical leaves, the acid and bitter juice of the fruit, and the concave oil-cysts of its rind. Its branches are also spiny, which is rarely the case with the sweet orange. The varieties in cultivation are numerous. The bitter orange was extensively cultivated by the Chinese, who used its rind to prepare medicinal poultices, as stomachic and tonic. Its chief use, however, is for flavouring puddings, cakes, &c., and for making marmalade. The Bergamot Orange (C. Bergamia) is noticed in a separate article.

Orange-leaves are feebly bitter, and contain a fragrant volatile oil, which is obtained by distilling them with water, and is known in the shops as Essence de Petit Grain. Orange-flowers yield, when distilled with water, a fragrant volatile oil, called Oil of Neroli, which is used in making Eau de Cologne and for other purposes of perfumery. The oil of this flower, and even of the rind of the bitter orange yield it, but those of the bitter orange are preferred. Dried orange-flowers, to be distilled for this oil, are an article of export from the south of Europe. They are packed in barrels, and mixed with salt. The dried flowers have a yellowish colour; the fresh flowers are white and very fragrant. The use of them as an ornament in the head-dress of brides is common throughout great part of the world. The small green oranges, from the size of a pen to the size of a cherry, which fall from the trees, both of the sweet orange and the bitter orange, when the rind is removed, are known as the Orange berries of the shops. They are used in making Curacao, and yield a fragrant oil on distillation, the original essence de petit grain. The dried and candied rind of the ripe bitter orange, well known as Orange-peel, is used as a stomachic, and very largely for flavouring puddings and articles of confectionery. The rind of the sweet orange is sometimes employed in the same way, but is inferior. A fragrant essential oil is obtained from the rind of the orange by distillation, and which is sold as Oil of Sweet Orange, or Oil of Bitter Orange, according as it is obtained from the one or the other, although the two kinds of oil are very similar. The rind of the orange is used in the preparation of a fine liqueur called Orange Roséglö, which is an article of export from some parts of Italy. Besides the use of the sweet orange as a dessert fruit, and as a refrigerant in cases of sickness, its juice is extensively used as a refrigerant beverage, and is valuable in febrile and inflammatory complaints.

Orange-trees are often extremely fruitful, so that they can sometimes be spaced a little more than 12 feet in diameter sometimes yields from 3000 to 4000 oranges in a year. One tree in Florida has often borne 10,000 oranges in a single season. The orange-tree attains an age of at least 150 years. Young trees are less productive than old ones. The fruit is also very juicy, has a thicker rind, and more numerous seeds.

The fruit of the orange-tree is of great commercial importance, for not only is it one of the most delicious and wholesome of fruits, but for turning it into marmalade is easily kept and carried from place to place. No tree of the same degree as the orange and its congeners, the lemon, citron, lime, &c., the property of being easily packed in boxes when nearly ripe, and being in that state able to stand the close confinement of a ship's hold during a voyage of two or three weeks. The orange is much cultivated in the Azores, Malta, Sicily, Spain, Portugal, the Syrian coast, and latterly in Florida, and it is from these localities that Britain receives its supply. Those from St Michael's, one of the Azores, and from Malta are the best varieties in the English market. A splendid East India Orange, carried the Navel Orange of South America are much superior. The latter occasionally reach Britain in small quantities from Brazil; they are nearly double the size of the ordinary orange, and have a peculiar navel-like formation on the top of the fruit, with a consequent diminished proportion of rind. Oranges when gathered for export must not be quite ripe; those fully formed and with the colour just turning from green to yellow are chosen. Each is wrapped in a piece of paper, or in the buss of Indian corn, and they are packed in boxes and half-boxes, chests and half-chests—the former are the Sicilian packages, the latter are St Michael's, Spanish, and Portuguese. A box contains about 250, a chest about 1000 oranges.

Orange-peel, or the rind of the orange, is used both in medicine and in confectionery—for the former purpose it is merely cut into long strips, and dried; for the latter it is carefully separated, either in halves or quarters, from the fruit, and, after lying in salt water for a time, is washed in clear water, and then boiled in syrup of sugar, or candied, and is sold extensively as candied peel. The rinds of the citrus and lemon are treated in the same manner. The wood of the orange-tree is yellowish white and close-grained. It is used for inlaying and for turnery.

The orange may be successfully cultivated in climates of moderate temperature of which does not fall below 40°. The tree prefers strong loam or clayey soil, but succeeds in any kind of soil if well fertilised. See Dr Moore's Handbook of Orange Culture (New York and London, 1883); and United States Consular Report on Fruit Culture (1890).

Orange, or Gariep, the largest river of South Africa, rises in the Kathlambo Mountains, in the east of the province, and, after taking in the tributaries of the Orange, flows through the Great Caledon, and the Great Bear, to enter the coast. The principal tributaries are the Caledon and the Vaal, both joining it from the right. Its volume varies greatly between the dry season, when it is not navigable, and the rainy season, when it overflows its banks in the upper parts of its course. Its mouth is, moreover, obstructed by a bar.

Orange, a town in the French department of Vardeune, on the left bank of the Aigue, 18 miles by rail of Avignon. The Arumsio of the Romans, which contained 40,000 inhabitants, it retains two splendid Roman remains—a triumphal arch, 72 feet high, and a theatre whose façade was 340 feet long by 116 high. A neighbouring circus has been swept away; all that remains is a cathedral, and statues of two of the counts. Pop. 6964. Orange was the capital of a small independent principality, which was ruled by its own sovereigns from the 11th to the 16th century. The last of these sovereigns, Philiibert de Chalon, died in 1531 without issue, and was succeeded by the Count of Nassau, and to that house the estates and titles passed. The Count of Nassau who obtained the principality of Orange was the father of William the Silent (see Holland, Vol. V. p. 742). William
ORANGE

III., Prince of Orange and king of England, having died in 1702 without issue, there began a long-continued controversy as to the succession between Frederick I. of Holstein-Gottorp (the grandson of the lineage and of Orange), the representative of the older branch of the House of Nassau (q.v.), and the head of the younger line. At the peace of Utrecht (1713) the king of Prussia took the settlement into his own hands, so far as the territory of Ulster, Ireland, and the British Dominions in Canada and the New World was concerned, being purchased for certain equivalents to the king of France. The title Prince of Orange, however, remained with the younger Nassau line, afterwards sovereigns of Holland. See Best's Histoire d'Orange (1836).

Orange, a city of New Jersey, 12 miles W. of New York by rail, and 3 miles by tram-car from Newark. The slope of Orange Mountain is laid out in beautiful parks, and ornamented with villas. There are manufactures of hats, carriages, &c. Pop. (1850) 13,207; (1900) 24,141.

Orange men, an organisation which has its origin in the hostility that subsisted between Protestants and Catholics in Ireland from the Reformation downwards, though the term is first used after the Revolution of 1688. The members of the Protestants' associations appear to have been known by the name of 'Peep-of-day Boys;' but the rude and illiterate mob of Peep-of-day Boys made way for the rich and influential organisation of the Orange Society. Its name was taken from that of the Prince of Orange, William III., who has been popularly identified with the establishment of that Protestant ascendency which was the object of the Orange association to sustain. The first 'Orange Lodge' was founded in the village of Longhedge, County Armagh, September 21, 1795. Lecky holds that the first Orange rising was brought about by the restlessness and discontent of the Catholics, consequent upon the withdrawal of Earl Fitzwilliam and the collapse of his schemes of Catholic emancipation, and was really a plan to expel all Catholics from Ulster, and drive them to Connaught or elsewhere. The immediate occasion of the crisis was a series of outrages by which Catholics were forcibly ejected from their houses and farms, terminating (September 1795) in an engagement, called, from the place where it occurred, the Battle of the Diamond. The rebellion of 1798 was only an episode in the religious and political antipathies. In November of that year the Orange Society had already reached the dignity of a grand lodge of Ireland, with a formal establishment in the metropolis; and in the following years the organisation extended over the entire province of Ulster, and, by its ramifications in all the centres of Protestantism in the other provinces of Ireland. In 1808 it extended to England. A grand lodge was founded at Manchester, but transferred to London in 1821. The subject more than four years later was the subject of a parliamentary report, especially in 1813, and in consequence the grand lodge of Ireland was dissolved; but its functions in issuing warrants, &c. were discharged vicariously through the English lodge. The most memorable crisis, however, in the history of the Orange Association was the election of the Earl of Carlisle (Cumberland) in 1827 as grand master for England, and, on the re-establishment of the Irish grand lodge in 1828, as imperial grand master. The Catholic Relief Act of the following year stirred up all the slumbering antipathies of creed and race, and the Orange Association was invested with more vigour than ever—not only in Wales and Scotland, but also in Canada and in the other colonies; and it extended its ramifications into the army. In 1835 the association numbered 20 grand lodges, 80 district lodges, 1,500 private lodges, and from 200,000 to 220,000 members. After a protracted parliamentary inquiry in 1835 the lodges were formally suppressed, though the institution afterwards gradually revived as a secret society. See Orange, of the Christian Churches and in British America. Great days in the association are the 5th of November, the anniversary of William III.'s arrival in Torbay; and the 1st and 12th of July, the anniversaries of the battles of Augusta, by Sir John Moore, and of the Boyne. Serious riots took place in New York on November 12, 1871, or rather in 1880 and 1886. See Lecky's History of England in the Eighteenth Century, vols. vii. and viii. (1890).

Orange River Colony, a British crown colony in South Africa, lying between the Vaal and Orange rivers, and surrounded by Cape Colony, the Transvaal Colony, Natal, and Basutoland. This region is a plateau, rising from 3000 to 5000 feet above the sea-level, with very little wood, except alongside the numerous watercourses. Its vast undulating plains of magnificent pasture-land slope down to the Vaal and the Orange, and are dotted over with the isolated hills called 'kopjes.' Area estimated 48,329 sq. m., bounded on the north by the Orange, and on the south by the Drakensberg. The annual trade reaches a total of 3 millions sterling; the chief exports being wool, diamonds, hides, ostrich-feathers, and live animals. When the Dutch Boers left the Cape Colony (1836) and took possession of this country it was inhabited by Bushmen, Bechuana, and Kordannas. The Cape government appointed a resident in the republic in 1845, and three years later it was annexed to the British crown as the Orange River Sovereignty; but in 1854 it was given up to the Boers, who formed themselves into the independent republic of the Orange River Free State (1848). President Prinsloo (1834-58) cherished the friendly relations with Britain, and mediated in 1851 between Britain and the Transvaal. On the failure of negotiations between the Transvaal (q.v.) and Britain in 1889, President Steyn, in alliance with the Transvaal, issued an ultimatum to Britain (9th October) which was virtually a declaration of war, and was followed a few days afterwards by a joint invasion of Natal. The Boer republics having been conquered and overrun, on 25th May 1900 the Orange River State was formally annexed by Britain as a crown colony, under the name of the Orange River Colony.

See Boers, Transvaal; Norris-Newman, With the Boers in the Transvaal and Orange Free State (1882); Anthony Trollope, South Africa (1878); E. de Weber, Quatre Ans dans Pays des Boers (1882); Theal's History of the Boers in the Orange Free State (1889) and numerous works on the Transvaal war (1889-1900).

Oratorio, a sacred story set to music, which, like opera, requires soloists, chorus, and full orchestra for its performance, but dispenses with the theatrical adjuncts of scenery, costumes, and acting. It is named from the oratory or mission-hall in Rome, where on feast days St. Philip Neri (q.v.) imparted by the same spirit as had in the medieval miracle and mystery plays sought to interest and educe the unlearned, arranged the sacred musical performances (1571-94), which developed into the modern oratorio.
ORATORIO

The effort to find a more dramatic vehicle of expression which had proved in Florence the germ of Opera (q.v.) was also being made in Rome by Emilio del Cavalli. Among the Italian composers who wrote the first oratorio and the first opera (properly so called) were produced in the same year (1690) in these two cities. Cavalli's oratorio, which was written throughout in recitative style, was called La Rappresentazione dell' Animai e del Corpo, and the direction for acting, dressing, and dancing, as well as the entire the conception of oratorio has changed since its first rude beginning. During the 17th century Carissimi and Scarlatti wrote many works full of expression, but the Italians were, as a rule, more engaged with the development of opera. Indeed, save in such expressive works as Carissim's Jeptha, Stradella's John the Baptist, and the like, there is no difference between opera and oratorio composition, and it was among the graver nations of the North that the oratorio was to arrive at its maturity. There the first and almost universal subject was the Passion, and to illustrate the story and direct the meditations of the devout, Schütz, Graf, Handel, and Bach employed all their skill in musical construction, and all the resources which counterpoint, harmony, and orchestration could afford. Part writing is absolutely necessary for such impressive and serious works as oratorios, and it is the neglect among the Italians of the art they had brought to such perfection during the 16th century which has caused the crown to pass from Italy to Germany. The greatest 'Passion Music' is the St Matthew, written for service on Good Friday, 1729, by Seb. Bach. It contains choruses, solos, and chorales (in which the congregation took part), all of surpassing interest and beauty, and showing when requisite great dramatic truth and force. And as this work is a climax, so it is the close of passion music development.

The next and most important phase of oratorio was the Epis, which became in Handel's giant hands such a powerful instrument. Before he wrote Saul and Israel in Egypt (1738) he had written an early oratorio in the Italian and German style. Between his arrival in England (1710) and his abandonment of the opera he had in no fewer than forty-four operas accented himself to all the possibilities of vocal expression; and his Italian training, his studies in Germany, and his variously slightly fitted his talent to the work. In twelve years he composed fifteen grand oratorios (Israel in Egypt, Messiah, Samson, Judas Macabbeus, Joshua, Solomon, Jeptha, &c.), besides several cantatas and anthems of almost oratorio dimensions. The greatest is Israel in Egypt, with its massive double chorus-writing and its grand effects; but the Messiah is a work which stands out not only among oratorios, but in all musical literature as a great inspiration. Pure inspiration it must indeed have been, for it was written in twenty-four days! The great admiration for Handel's compositions in England finds expression every three years in the Handel Festival, held in London, at which the Messiah, Israel in Egypt, and a selection are performed on a gigantic scale (about three thousand singers and five hundred instrumentalists).

Haydn heard Handel's works when he visited England in 1776, and in the early position of his great oratorio, the Creation (and also the choral pastoral the Seasons, which should scarcely be called an oratorio); in fact, Handel has been the inspiration and model of nearly all succeeding oratorios, as England, his adopted country, has been since his time. There the unequalled choruses and the general custom of choral festivals on a large scale offer numerous opportunities for producing familiar masterpieces and inducements to compose new works. For the Birmingham Festival of 1846 L. Mendelssohn wrote his Elijah, a work of great originality, which, however, owes more to the influence of Bach than of Handel. St Paul was produced at Düsseldorf ten years earlier.

During orchestral colour and original effects characterise Stolz's oratorios, Last Judgment (1758), Crown of Thorns (1796), Christ in the Wilderness (1826), and Dvorák's St Ludmila and Liszt's St Elizabeth and Christus lead more and more to the form of dramatic cantata, of which Beethoven's Mount of Olives (miscalled an oratorio), Schumann's Paradise and the Peri, Sullivan's Golden Legend, and Mackenzie's Dream of Jubal and Saul are fine examples.

To treat of the large field thus opened to modern composers in the dramatic cantata, sacred and secular, would lead us far beyond the limits of this article; reference must be made to musical dictionaries, and we must content ourselves with mentioning Bitter's Geschichte der Oratorienus (1872), Wagner's Geschichte des Oratoriums (1882), Rockstro's careful article in Grove's Dictionary, and Upton's Standard Oratorios (Chicago, 1887).

**Oratory of St Philip Neri, Congregation of The.** The origin of the Congregation of the Oratory has been described in the article on St Philip Neri, its founder (see NERI). Here something must be said of its constitution and work. The primary idea of the institution was that its members should be bound by no religious vows. They were to be secular priests living together under a common rule, and practising obedience as free subjects, with liberty to quit the community if they so willed. Each father must contribute an annual pension towards the upkeep of the house, and have, moreover, a sufficiency of private means for his personal expenses. Otherwise he has absolute control over the money which the members of the congregation is of a remarkably republican character. Each community is entirely independent, being subject to no mother-house or general superior. The community is composed of three classes—the novices, triennial and decennial fathers. In the triennial class a father after three years becomes a triennial father, with a consultative voice in the affairs of the congregation. On the completion of his tenth year he becomes a decennial father, with a decisive vote. The superior, who is generally spoken of as 'the Father,' is elected every three years, and, with him are elected four deputys, who form a committee which meets weekly, has the appointment of the other officers, distributes the ecclesiastical work, and controls the ordinary expenditure. But no large expenditure or new undertaking can be entered upon without the consent of the general congregation, in all cases the voting is by ballot. The father superior, primus inter pares, has no privileges and is exempt from all rules. He takes his turn in the waiting at table in the refectory, and has his share in the work of the church. The principal religious exercise of the community, common to all priests, is half-an-hour's mental prayer in the evening followed by the litanies, for which three times a week is substituted the taking of 'the discipline' or self-flagellation in a darkened room. The ceremonial for this exercise will be found described in Home's Ancient Mysteries. The ministerial work of the Oratory consists chiefly in
constant attendance in the confessional and in the characteristic daily preaching. Another essential part of the institute is an external brotherhood similar in some respects to the 'Third Orders' of the religious orders. It was admitted by canon law that any penitent, whether a common or private person, might apply to the master of the order, or any other priest, for admission to the religious life in his or her own place, and so become a brother or sister of the order.

The Brothers, as a rule, observe the same exercises as the fathers. It is in the Little Oratory that the musical services which originated the oratorio were so often celebrated. The oratory at Seville that Blanco White speaks of it as the 'spiritual opera-house.' Philip Neri, who governed the community at Rome as long as he lived, committed no rule to writing. The traditional rules drawn up at a later time were approved by Pius V. in 1612.

The Oratory spread rapidly through the chief cities of Italy, and there were several houses in Spain. In Germany it never took root. In France Cardinal de Bérulle took the institute as his model for a new foundation (1611), approved by Paul V. 1614, under the name of the 'Congregatio de Oratory of our Lord Jesus Christ in France.' But it differs essentially from the Oratory of St Philip Neri. It was governed by a superior-general, and was mainly concerned with the institution of seminaries for the training of priests.

The life in the Roman Oratory is devoted leisure for private study; and the founder, in encouraging Cesare Baronio to write his great work on church history, set an example which was followed by many distinguished scholars—Buzo, Gallonio, Angiulli (Rome universitatis), Bianchini (Elen gium quadruplex), Gallandi (Bibliotheca patrium), and others. It was natural that the character of Philip Neri and the community life which he established should have a particular attraction to a number of men from the English universities, who were led by the Oxford movement to the Church of Rome. Dr Newman when at Rome obtained from the pope a brief (26th November 1847) authorising him to establish the Oratory in England. Shortly afterwards F. W. Faber, who had founded a new order, the Brothers of the Will of God, generally known by the name of the Wilfridians, was admitted, with the whole community, the Oratory at Birmingham. In 1849 Father Faber was sent to London with some other fathers to set up a house in King William Street, Strand, which in October 1850 was constituted an independent congregation, and in 1854 was transferred to a new building at Highbury.
Too often the orchard is treated with contempt, as a space where the children, turkeys, calves, or pigs may roam at pleasure; and if there are any apples they are regarded as a windfall of some rarity. This is wrong, and it is believed we laid out, at a time when there was room enough to move freely, and people knew less than they seem to know now. Accordingly we find on these old trees either no fruit at all, or very little, and of that the chief part worthless. There is no greater point to the farmer or squatter farming his land than the sad condition of his orchard and his own deep ignorance about it.

Amid the more important works the trees have too often been neglected; and the space which should yield its fair share of profit, as well as of picturesque enjoyment, has become a frowsy wilderness.

Much of the blame for this would fall on those who are now beyond it. Seldom indeed can we find an orchard planted by our ancestors with any common sense or judgment. The trees have been planted in rows, without knowledge of their habit, growth, fertility, use, or requirements. And for this the nurserymen of that time must also be held accountable, their ignorance of their own produce having been equal to that of their customers. In this particular a vast advance has been made in the last one hundred years, and the planter of an orchard now has himself to thank if his plants amiss. For of late years it has been imagined largely that profit, equally speedy and heavy, can be secured very pleasantly by the growth of fruit in Britain. In spite of all experience this may be so, as we find the laws of nature overcome now and then by superhuman effort. And when everything comes to pass exactly as it should, the orchard takes occasion sometimes to pay its way.

With a view towards this we may consider first the formation and planting of an orchard; secondly, the removal of an old and not too hale plantation.

(1) Situation and soil are the first two questions, the former being even the more important in the colder parts of Britain. A slope towards the south or south-east is best of all; but if that cannot be found a fair level will do, unless it be in the bottom of a valley or in any low situation. A deep, rich, and close situation is always bad; and especially evil is the spot—though it may be the warmest in summer—where the fog of the morning draws and packs from the marshes or from a tidal river. For the worst of all enemies to British fruit is the late spring frosts, which is chiefly in the plain; whence the bleak hillside is often fruitful when the sheltered dale is barren. Also the soil must be fairly good, neither too sandy nor of very heavy clay. When the site has been chosen the ground should be trenched to the depth of two feet if possible, and drainage provided where needful, as in all but the most favoured spots it is. Time for settlement should be allowed after the trenching; and then the stations may be prepared for the standard-trees. The distance from tree to tree and row to row ought to be governed by the choice of kinds, and this again depends upon the object of the planter. He may plant for home use, or for sale, or for both; and in either case for table use or for cider. If he plants for his own table use—be it for cooking or dessert—his chief concern is quality combined with fair fertility. If he plants for sale he must supply his customers with white and appearance and the common opinion of his neighbourhood; for if he took into the market the best apple ever grown, but as yet of no reputation, he would have to take it home again until the trees grew old. Also, he would rather sell good fruit than bad; but generally speaking this is difficult without much self-sacrifice. For the finer kinds are, with few exceptions, less fertile than the inferior. But whatever his objects be, and whatever varieties he selects, the planter must be guided by the habit of the trees as to the space they require—e.g., the bigger trees allowed more space than too little; and in a plantation intended to endure, 25 feet from tree to tree is not one too many. The permanent trees should be straight standards, worked upon the crab-stock, and with 6 feet of stem from the root to the spread of the branches. Let them be planted almost upon the surface, then banked up with good soil, and staked securely, until they can hold their own against the wind. Of pruning little or none is required during the first year of their growth, except that any weak shoot should be cut out, or rival to the leader suppressed. If the plant in small conical form. No manure should be given as yet, unless it be in the way of mulching, where the soil is very droughty. When all the standards are planted and staked, and seen to 'cut true,' as gardeners term it, both along and across the rows, the tender shoots may with advantage be protected whether of dwarf-trees, or of bushes, vegetables, clover, or anything else; but a clear space must be reserved at all times of at least a yard around the orchard-tree. And throughout the next year the young plant must be heeded frequently, regulating the supply of water in case of protracted drought, restaked or rebound if any break loose, and watched that no grub or other vermin bore the slender stem, or injure bark, branch, or foliage. In the second year judicious pruning will be needed, for which see our article on that subject. The ground between the trees may be cropped with grass or clover (not allowed to become too long), which can be broken up for the purpose of manuring, and at other times saves the dropping fruit from bruises. With regard to varieties it is quite impossible to offer useful advice without a knowledge of each special case. If the planter is providing for his own household he generally knows what suits it best and lefts the situation. If he grows for market he can have recourse to the counsel of some good nurseryman acquainted with the neighbourhood, its wants and condition, and can save much by consulting the plans of that important old grower so well known as to his name, clean, well grown and healthy; for in no line of business has there been more advance during the last half-century than in that of the nurseryman.

(2) With regard to the renewal of an ancient fruit-grove to the best of its best, or any coming into possession or management of a decretive orchard may wisely allow one fruiting season to show what good there is in it. All trees of valuable kind may then be marked for better cultivation, while the rest are divided into those worth grafting and those that are worthy of the domestic hearth; and the last will perhaps be more numerous. The trees that have goodness or beauty of fruit, with vigour sufficient to carry it, should at once be relieved of all moss and decay, struggling or worn-out or ill-placed members, or thickety growth of feebly wood, and perhaps in some places be cut back with discretion. Then the ground should be opened around the trunk, with tender avoidance of all upper roots (if any still live as a rarity), and a mulching of good, rich manure shall be laid on in the winter-time; or, failing such encouragement, a frequent dressing of superphosphate or nitrate of soda on the feed in summer-time. The difficulty is to get this new supply to the parts that are fit to take it up, and then to provide the proper dose. And none but a man who knows the nature of a tree should be permitted to attempt it. Too often the roots of these old trees are groves that sink downwards nightly, in the manner of a well-
ORCHIDS

grown cannot, leaving nothing with a mouth for better feeding reasonably near the surface. Little improvement must be looked for during the first season, but even then there should be symptoms of increasing vigour, and in the second year the tree should be making healthy growth again.

Those that are of inferior kind, but have kindly wood, may be grafted back in shortened home, with the dry and ragged wood removed. Then in the spring let fair stout scions of the better sort be inserted, chosen from strong growers, such as impart their own vigour to the stock; for it is vain to work a feeble kind upon a strong. This kind will sometimes be a great success and sometimes downright failure, according to the harmony of stock and graft, upon which point the most experienced gardener as yet knows very little.

Many old trees, as before suggested, will be fit for no subsequent use; these should be grubbed up at once, not with a feeble hand, but following every root as if you hated it. Then let a large space be excavated and filled in with abundant fresh soil trodden at every layer, and upon this young standard plant vigorous kind, and, as soon as possible, may be, and hanked up and staked. None but the strongest and most rapid growers can hope to make good these gaps among the elders, and even so they will be long about it.

The virtue of patience must be highly cultivated by the most dexterous, for ancient orchards set the renewal of an old plantation little can be said as to choice of sorts without thorough knowledge of locality. Many apples that become a picture in Kent or Surrey or Devonshire are plain little dowses in Yorkshire, and unsightly scrubs in Scotland; while others that are comely and good in the north are rapid in the southern counties. Again, few or none of the American kinds, so handsome and fine when imported, can be grown to perfection in Great Britain. The conferences of the Royal Horticultural Society have afforded most valuable hints upon this subject, and these reports should be studied with care. Much may also be learned from recent treatises by pomologists, such as Dr Hogg's Fruit Manual; John Scott's Orchardist; the works of the late Thomas Rivers, and the fruitlists of the present T. F. Rivers, Fruit for Profit, by George Bunyard of Maidstone; and a concise work on the same subject by Mr Wright of the Horticultural Journal. See Apple.

Orchardson, William Quiller, a genre-painter, who is considered to bear the palm in this branch of art, surpassing all other English physiognomists in accuracy, expression, and dexterous execution. He was born in 1838, in Edinburgh, where he studied under Scott Lauder at the 'Trustees' Academy; he became A.R.A. in 1868, R.A. in 1877, and received a Medal of Honour at the Exposition Universelle, 1878. Best known among his exquisite and highly-popular pictures are 'The Challenge' (1865), 'The Duke's Antislavery' (1859), 'The Protector' (1871), 'The Bill of Sale' (1875), 'The Queen of the Swords' (1877), 'A Social Eddy' (1878), 'Hard Hit' (1879), 'On board H.M.S. Bellringon, July 23, 1815' (1880); bought by the Chantrey bequest, the National Gallery (1884), 'After' (1886). The Salon of Madame Récamier' (1885), 'The First Clou' (1887), and 'The Young Duke' (1889). On the artist, who is D.C.L. of Oxford, see the Portfolio for February 1895 by W. Armstrong.

Orchestra, the part of the Greek theatre where the chorus danced; with us, the part set apart for the band; hence now frequently the band itself, in a theatre or at a concert. For the development of the orchestra in this latter sense, and the partition of instruments in a representative orchestra, see Music, p. 360. See also Band, Theatre.

Orchids (Orchideae or Orchidaceae), a natural order of endogenous plants distinguished from all other orders in the same alliance by their irregular gynandrous flowers and parietal placenta. The essential peculiarities of the order are due to the consolidation of the stamens and pistil into one body called the column; to the suppression of all the anthers but one in all the genera except those comprising the tribe Cypripedie, in which there are two anthers; to a peculiar condition of the pollen and the structure of the anthers containing it, and to the remarkable forms and development generally assumed by the lip (labelatum)—one of the inner members of the perianth which often plays an important mechanical part in the fertilising of orchids. The species are perennial herbaceous plants or shrubs of terrestrial habit in the temperate and colder parts of the world, but in warmer countries become epiphytal, adhering to the stems and limbs of trees, or fixing themselves on rocks by their strong fasciculate roots without penetrating the structure of these, or having any direct connection with the soil. Hence they have been popularly named air plants, as those which assume the epiphytal habit derive the greater part of their nutriment from the atmosphere. Their roots are fibrous or fasciculate or fleshy and subterranean, the latter being peculiar to the terrestrial species. Their stems are annual, herbaceous, perennial, and woody, and very often pseudo-bulbous. Their leaves are flat or round, equitant, and generally sheathing, often leathery, and having parallel nerves. The flowers are irregular, extremely variable in form, often beautifully coloured, and deliciously fragrant, and are either solitary or in spikes, racemes, or panicles. They are composed of six usually petal-like segments: the three outer ones are called sepals, and two of the inner ones, which are usually alike in form and colour, are called petals; but the third one, which differs in shape and also generally in direction from the others, is the lip. Opposite to the lip in the axis of the flower is the column, bearing the anther or anthers with the pistil variously situated relatively to each other. The more obvious features described are well illustrated in the accompanying figures of Cypripedium (see also Lady's Slipper), Mormodes, Odontoglossum, and Oncidium, in which the six segments of the perianth are so conspicuous as to reveal at a glance their structural relation to each other.

Fig. 1.—Cypripedium Boxallii.
Orchids are found in almost all parts of the world, except in extremely dry climates and on the borders of the frozen regions. In Britain there are found sixteen genera and nearly forty species. In Europe, the temperate parts of Asia, in North America, and the Cape of Good Hope they are common. Inhabitants of groves, marshes, and meadows; and in these regions they are invariably terrestrial in habit. But in the hot damp parts of the West and East Indies, in Madagascar, and other islands in the same region, in the moist forests of Brazil, the warm parts of Central America, and western Mexico they abound in the greatest profusion, no longer dependent on the soil for their nourishment, but clinging to the trunks and branches of trees, to stones and crags, where they vegetate among ferns and other shade-loving plants, or occupy themselves exclusively the places which they affect. The family is a very numerous one, being, according to the Genera Plantarum, 334 genera and about 5000 species known to botanists. Of exotic species Linnaeus knew only about a dozen a little over a century ago. About 2000 species have been introduced to cultivation. The beauty and the fragrance of the flowers, the singularity and almost endless variety of form which they exhibit, and their interesting structure botanically, along with the rarity of many of the most beautiful, place orchids among the most remarkable of the families of the vegetable kingdom. Darwin, who devoted much attention to the family, particularly in regard to their fertilisation, says of the peculiarity of the structure of the flowers of orchids that 'an examination of their many beautiful contrivances will exalt the whole vegetable kingdom in most persons' estimation,' and that 'hardly any fact has struck him so much as the endless diversities of structure—the prodigality of resources—for gaining the

Fig. 2.—a, Masdevallia cimenter; b, M. Schlumbergii.

same end, namely, the fertilisation of one flower with pollen from another plant.' This part of the history of orchids is, like every other point connected with them, too wide to be dealt with here in detail. Those, however, who desire to study

the matter closely should see the work quoted from

'The Fertilisation of Orchids,' by Charles Darwin.

Since the middle of the 19th century the cultivation of orchids in Britain, on the Continent, and in America has become an absorbing pursuit with wealthy amateurs. The possession of a rare or unique species or variety is an ambition that can only be attained by the millionaire; the prices of such are quite beyond the means of those possessed only of moderate wealth. Syndicates are formed for the purpose of collecting and importing orchids from all countries in which rare or otherwise valuable species are known to exist, and private persons and several of the leading London and continental nurserymen send experts in orchid-collecting to those countries at great expense with the same object in view. There is thus considerable commerce in orchids, in connection with which large sums of money are circulated annually. The genera which are in greatest request among amateurs are Cypripedium, Dendrobium, Masdevallia, Odontoglossum, Cattleya, Lelia, Oncidium, Chysis, Cymbidium, Calanthe, Phalaenopsis, Cattleya, Angrecum, Vanda, and many others.

Amongst notable English collections have been those of Baron Schroeder at Egham in Surrey, and Sir Trevor Lawrence at Dorking, each of which must have cost its owner from £20,000 to £40,000 to bring together. Among large commercial collections are those of Veitch, Williams, Low, and Bull, all of London, Sanders & Co. at St Albans, and in Scotland of Messrs Thomson at Closenfords. Sales by auction, at which orchids to the value of thousands of pounds may change hands, take place frequently in London, which is the centre for the world of the trade in orchids. The prices of individual plants vary from 3s. 6d. to hundreds of pounds, the prices depending on qualities of size, form, colour of flower regulated by canons appreciable only by connoisseurs. Baron Schroeder sold a unique plant of Cypripedium Stonii, var. Phalae-lemmum, for £365; another connoisseur paid £240 for a variety of Aechmea Lawrenceae. The ordinary form of the latter may be obtained for about two impecunia per plant, and that of the preceding species for half a guinea each, simply because they are more or less plentiful, while rare or unique forms command hundreds of pounds sterling. These unique forms make their appearance very generally without any exercise of skill on the part of the fortunate possessor. They may be bought along

Fig. 3.—Mormodes Ocanus.

Fig. 4.—Odontoglossum Harrymanum.
with ordinary or typical varieties of the species to which they belong, and not having been seen in flower by the dealer, their intrinsic value is not known to him. Thus Cattleya Thomsonii originated in part of an importation of Cattleya Mossiae and other species received from South America. Only one small plant appeared in a numerous batch of plants, with the unique characteristics of the one in question, which was readily bought for £200.

The cultivation of orchids is accounted a difficult branch of the gardener's art. When the value of a considerable collection of rare kinds is considered, their successful multiplication is a reasonable undertaking. To be successful in their treatment the cultivator should above all things be well informed regarding the conditions under which each species grows in its native habitat. The prevailing temperature and other atmospheric conditions during the periods of moisture and rest, and the amount of shade or of light to which they are exposed at those seasons, must be known to and comprehended by the cultivator before he can adapt his means to the end in view. Houses or compartments of houses, set apart for the accommodation of species which are native of the more hot and humid parts of the world, such as tropical East India, Malagascia, and Brazil, and a similar arrangement is made for those from Mexico and Central America. The management of the atmosphere of these houses is then based upon such knowledge as the cultivator possesses regarding the temperature and moisture, light and shade, that prevail in the countries the several species are natives of. The plants of truly epiphytal habit are usually cultivated on blocks of oak, teak, or other timber, with or without moss about their roots for the retention of moisture. All classes are also grown in pots or lattice-baskets, in rough fibrous peat and Sphagnum moss largely intermixed with charcoal and porous crocks, to allow drainage.

Only the terrestrial species are grown in soil proper, and as there are exceedingly few of such that require the accommodation of special houses, space need not here be taken up with their requirements. The propagation of orchids is effected by division of the root-stocks, by separating the pseudobulbs in some cases, by cuttings in the case of Dendrobiums, and some others with similar forms of growth, and by seed in all cases when it can be obtained, which rarely occurs with cultivated plants except they have been artificially fertilised. Increased interest in orchids has in recent years been evoked by the success that has attended the efforts of hybridists to unite the desirable features of the flowers of any two species in one form. The pioneer in this branch of orchid culture was Mr. T. H. A. Dalmont of London, whose first success occurred about the year 1860. Many hybrid orchids are now in cultivation, but they all belong to very few genera; certain species of Cattleya, Cattleya, Cypripedium, Dendrobium, and Epidendrum being all that have yet yielded to the hybridist's art. Few orchids yield products useful to man. Of these the Vanilla (q.v.) is perhaps the best known in commerce. The leaves of Asprenum frangrans, a native of the Mauritius, where it is called Fadum, and by the French Isle of Bourbon Tea, are delightfully fragrant, having the odour of Tonquin bean with the flavour of bitter almonds, and are said in infusion to promote digestion, and to allay coughs, diseases of the chest, and spasms. The roots of Helbeborine (Epipactis latifolia), a British species, are said to allay arthritic pains. Those of Himantoglossum hircinum, Spiranthes antonianus, and Platethorea bifolia are reputed to be aphrodisiac. The flowers of Gymnadenia conopsea, a native of Britain, has been administered in dysentery. In North America the tubers of Arethusa are used to stimulate indolent tumours and to allay toothache. The roots of Spiranthes divaricata are much esteemed as a diuretic in Chili. The rhizomes of Cypripedium fasciculatum and of C. parryi form are regarded by American practitioners as an excellent substitute for Velarian as a gentle stimulant. The tubers of Aplectrum hyemale are so viscid that they are called Putty-root in the United States, and are there used for cementing broken earthenware.

**Orchis** is a genus of Orchidaceae, to which, as now restricted, ten of the British species are referred. Some of them are among the most common of British Orchidaceae, adorning meadows and pastures with their flowers in summer. It is a rather numerous genus, chiefly spread over Europe, northern Asia, and a very few of the species belong to North America. The British species have mostly red or lilac flowers, sometimes white or green, and often beautifully mottled. The roots of some of the species when dried constitute the salep of commerce, which reduced to a fine powder, and mixed with boiling water, sugar, and milk, makes an excellent diet drink. *O. mascula* and other British species yield such an excellent fecula that it has been suggested the production of salep might be made a profitable industry in England. The accompanying figure gives an idea of the general features of the genus.

**Orchil.** See **Archil**.

**Orchomenos**, an ancient city of Boeotia, the capital of the kingdom of the Minyae, was situated at the north-western corner of Lake Copais, where it is joined by the Cephissus, and extended from the marshy edges of the lake up the face of a steep rocky hill, on which stood the acropolis. It sent thirty ships to the Trojan war, and at a later date became a member of the Boeotian confederacy. Its government was thoroughly aristocratic, and after the Peloponnesian war the jealous democratic Thebans destroyed it by fire, and sold its inhabitants as slaves. It was rebuilt in the reign of Philip of Macedon, but never recovered its position. It was famous for its musical festival in honour of...
of battle. *Fire ordeal* had only allowed to persons of high rank. The accused had to carry a piece of red-hot iron for some distance in his hand, or to walk nine feet barefoot and blindfolded over red-hot ploughshares. The hand or foot was bound up and inspected three days afterwards; if it had been dressed, had healed, or pronounced innocent; if otherwise, guilty. Under such a judicial system there were probably few acquittals; but there can be little doubt that in the severer kinds of ordeal precautions were taken by the clergy to protect those whom they wished to clear from false accusation. And, that many of these jugglers suggest possibilities of official trickery which may at once have saved the credit of the ordeal and cleared those meant to be acquitted.

Queen Emma, mother of Edward the Confessor, when suspected of a criminal intrigue with Avelyn, Bishop of Winchester, triumphantly vindicated her character by walking unharmed over red-hot ploughshares. *Water ordeal* was the usual mode of trial allowed to bondsmen and rustics, and was of two kinds—the ordeal of boiling water and of cold water. The ordeal of boiling water, according to the laws of Edward the Confessor, required that the accused put his right hand into boiling water, where the hand had to be inserted as deep as the wrist; what was called the triple ordeal deepened the water to the elbow. The person allowed the ordeal of cold water—the usual mode of trial for witchcraft—was flung into a river or pond; if he floated without any appearance of swimming he was judged guilty; while if he sank he was acquitted.

The *vogier of battle* was a natural accompaniment of a state of society which allowed men to take the law into their own hands. The defeated party, if he craved his life, was allowed the opportunity of an *oral* fight, or retracting the perjury which he had sworn to.

Other kinds of ordeal were practised in particular circumstances in different parts of Europe. In the ordeal of the *fire*, a suspected murderer was required to touch the body of the murdered man, and pronounced guilty if the blood flowed from his wounds. Undoubtedly this touched a primitive time, when death was not fully understood, and the lifeless body was supposed still capable of thought and action. And to this day English peasants expect every one who sees a corpse to touch it with their finger to see that he is still alive. The ordeal of the *environet* was in use among the clergy: the accused party took the sacrament in attestation of innocence, it being believed that, if guilty, he would be immediately visited with divine punishment for the sacrilege. A somewhat similar ordeal was that of the *corncob*, or consecrated bread and cheese: if the accused swallowed it freely he was pronounced innocent; if it stuck in his throat he was presumed to be guilty. Godwin, Earl of Kent, in the reign of Edward the Confessor, when accused of the murder of the king, allowed a *laldey* ('clearing') before a cross, and he who first fell, or shifted his position, was pronounced guilty. It was done away with as being irrelevant towards the mystery of the cross. Besides these, there was the ordeal by *lot*, dependent on the throw of a pair of dice, one made of ivory, and a cross of wood. The accused and one of the church were lined up, with the accused on the right hand. Trial by ordeal at first carried with it the sanction of the priests as well as of the civil power, though the clergy in the course of time came to discontinue it. In England it seems to have been continued till the middle of the 13th century.
ORDER

On the Continent it was, generally speaking, abolished rather earlier, although as late as 1498 we find the truth of Savonarola's doctrine put to the test by a challenge between one of his disciples and a Franciscan friar to walk through a burning pile. In Scotland, in 1560, the Act of Union, enacting, in one of the assemblies of the frank tenancy of the kingdom, which were the grem of parliaments, that no one was to hold an ordinary court of justice, or a court of ordeal, whether of battle, iron, or water, except in the presence of the sovereign himself, was passed. If the accused failed to appear, the court might be held in his absence. The first step towards the abolition of this form of trial in Saxon and Celtic countries seems to have been the substitution of compurgation by witnesses for compurgation by ordeal. The near relatives of an accused party were expected to come forward to swear to his innocence. The number of compurgators varied according to the importance of the case; and judgment went against the party whose kin refused to come forward, or who failed to obtain the number of compurgators. To repel an accusation it was often held necessary to have double the number of compurgators who supported it, till at length the number of numerous compurgators carried the day.

See the articles Battle (Wager Of), Divination, and Masonry also the works of Bastian, Glinn, Tyler, and Waitz passim; Tyler's article, 'Ordrels and Oaths,' in Macmillan's Magazine for 1876; H. C. L. E. Sc., Superstition and Force (Phila. 1866; new ed. 1878); and George Nelson's Trial by Combat (1890).

Order, in Natural History, a group inferior to class and sub-class, but superior to family, genus, &c. The term NATURAL ORDER is used in Botany to express genuine relationship in contrast to purely artificial grouping, but all orders now recognised are supposed to be more or less 'natural.' Sculls.

Ordericus Vitalis, a medieval historian, born at Atcham near Shrewsbury in 1075. He was the son of Oderic of Orleans, who in Roger de Montgomery's train had accompanied the Conqueror to England, and from childhood was dedicated to God. At ten he was sent to Normandy, where initiated at the church of the abbey of St. Evroul. Here he spent all his life, although he made several visits to England to collect historical materials. He became a priest in 1106, and died most probably about 1143. Between the years 1130 and 1141 Orderic compiled his Historia Ecclesiastica, an elaborate work on the history of Normandy and England, preceded by a brief chronicle of events from the birth of Christ down to his own time. The work is a singular mixture of important history and trivial gossip, marred by absolute lack of order, grotesque style, and laboured grandiloquence; but its writer possessed the seeing eye and the sympathetic heart, and the result is that his confused book remains a precious storehouse to the historian, abounding in those truthful photographic glimpses of reality which are beyond the reach of all the laborious erudition of a later age. With the Conquest it becomes of great value as an honest and trustworthy contemporary source.

The first edition of the Historia Ecclesiastica was published by Duchesne, in his Hist. Norm. Script. (1810). It was the subject of many subsequent editions (1840), and was translated into English by T. Forester (4 vols. 1853-56) in Bohn's Antiquarian Library. The best edition is that by A. le Brevoit (5 vols. Paris, 1838-55) as seen in his History of the Church of England (2 vols. 1870).

Orderlies are non-commissioned officers or soldiers employed as messengers or attendants. Thus, in the British army, each general or commanding officer has an orderly always at his disposal; a Post-office Orderly fetches the letters of each corps; and when a court-martial or board of officers is convened, a non-commissioned officer is appointed as Court-orderly to attend upon it. The men of the medical staff corps, who attend the sick, are also called Hospital-orderlies. The Orderly-officer is the officer on duty for the day in each corps. He attends all parades, inspects regiments, visits the barrack-rooms at the dinner-hour, hospital, cells, guardroom, &c., remaining there until his post is vacated. The next day he is ordered elsewhere. Similarly, an Orderly Non-commissioned Officer of each corps is on duty for the week, calls the roll, warns men for parade, copies orders, &c. The regimental Orderly-room is the office where the lieutenant-colonel, assisted by the adjutant and a staff of clerks, transacts his business and sees prisoners daily. Each troop, battery, or company has a similar Orderly-room for the use of its command. The Orderly-book or Order-book contains the general or regimental orders, which are copied into it as they are issued.

Orders, Holy, an institution, regarded in the Greek and Roman churches as a sacrament, by which ministers are specially set apart for the service of religion. While some of the reformed churches altogether deny the distinction of ranks in the ministry, none of them admits more than three ranks, of bishop, priest, and deacon. But in the Roman and Greek churches a distinction is made between the major or holy orders and the minor orders. The major orders are those of bishop, priest, and deacon (see the articles under those heads). A fourth rank of sub-deacons is generally reserved to one of the clergy of greatest age, its functions closely resembling in their nature and their degree those of the deacon. Some theologians, it should be noted, regard the episcopate not as a separate order, but as the completion and extension of the priesthood. The minor orders in the Roman Church are four in number—those of deacon, sub-deacon, reader, exorcist, and acolyte. To none of these orders is any vow of celibacy annexed. Some of their functions had their origin in the peculiar religious condition of the early church. Preparatory to the receiving of these orders candidates are the ordinands. The Roman Church the sacrament of holy orders is held to produce an indelible character, and therefore to be incapable of being forfeited and of being validly repeated. The Greek Church has also the distinction of major and minor orders; but all the functions of the four minor orders of the Roman Church are united by the Greeks in one single order, that of reader (anastostos).

In the Anglican and other Reformed Episcopal churches the three higher orders of bishop, priest, and deacon are alone retained. An Anglican clergyman may be deprived of his benefice, or suspended by his bishop for various ecclesiastical offences. But, in the usual case of deprivation, the clergyman does not forfeit his status of priest or deacon, which can only be lost by deposition or disrobing. Disrobing, which is only practicable by his metropolitan, with or without the co-operation of a synod of the bishops of the province, but it has been questioned whether he can be lawfully deprived of his orders as bishop. Till 1870 a clergyman of the Church of England could not be deprived of his benefice (see Clergy). In the Presbyterian and other non-episcopal churches the ceremony of ordination is not held to impart any indelible character. A minister found guilty of heresy or immorality is deprived of his office by deposition, by which his clerical status is forfeited. A minister deposed ceases altogether to be a minister, and is no more capable of any of the
functions of the office than if he had never been ordained. There is nothing to prevent a minister of the Church of Scotland, or any Presbyterian or Independent church, from being a member of the British legislature.

The use of a ceremonial for ordination is traceable among the Jews, and the New Testament contains frequent reference to the specific ceremony of 'laying on of hands' (Acts, vi. 1-7, xiii. 1-4, xiv. 23; 1 Tim. iv. 14, v. 22; 2 Tim. i. 6). In the Reformed and Episcopal churches in church order, this rite of ordination is held to be sacramental, and it is reserved, at least as regards the major orders, exclusively to bishops. In extraordinary cases it was permitted to cardinals and to certain abbots to confer the minor orders. Considerable controversy exists among Catholic writers as to what are the essential portions (Materia Sacramenti) of the rite of ordination. Some place it in the ‘imposition of hands,’ some in the ‘presentation of the instruments’ symbolical of each order. As regards the validity of the rite of ordination, the mere fact of its being conferred by a bishop suffices; but there is not any part of the Roman discipline which is more jealously guarded by laws than the administration of orders. The candidate can only be lawfully ordained by his own bishop (propris episcopis), or with the authority of his own bishop, who is ‘his own’ in respect of birth, domicile, of benefice, or of connection by personal service.

In the Church of England and other Reformed Episcopal churches the rules of the ancient canon-laws are retained, by which no one could be ordained without previous examination of his fitness, or who was disqualified by bodily infirmity, illegitimacy, immorality, or simony, or who was unprovided with a title (i.e. an appointment to serve in some church) which should provide him with a maintenance; or who, being a candidate for deacon’s orders, was under twenty, and for priests, under twenty-four years of age; but the age for admission to deacon’s orders is changed to twenty-three. In other Reformed churches ordination is performed by the presbytery by imposition of hands, or by one or more ordinary ministers. Some smaller Protestant denominations have no ceremony of ordination whatever.

Orders in Council, orders by the sovereign with the advice of the Privy-council. The Privy-council of Great Britain has no power to legislate, except so far as authorised to do so by parliament; but in periods of emergency it has nevertheless occasionally issued and enforced orders of a legislative kind; those who were concerned in passing, promulgating, or enforcing the orders trusting to parliamentary protection, and taking on themselves the personal responsibility of the proceeding. In such cases an act of indemnity afterwards passed has relieved from liability those who advised the order or acted under it, and given compensation or punishment to those who suffered as a result. This course was adopted in 1766 with regard to an embargo on the exportation of corn, issued in consequence of a deficient harvest and prospect of famine. An important constitutional question was decided by the famous Orders in Council issued by Great Britain in 1806 in reprisal for Napoleon’s Berlin and Milan decrees. See Continental System.

Orders of Knighthood or Chivalry, with their respective statutes and insignia, seem to have been the result of the desire to institute a superior class among those who devoted themselves to arms, and may be said to have originated between the ages of Charlemagne and that of the Crusades; though the Romans, in their equestrian order going back to the 6th century B.C., and many other of the ancient nations, had similar distinctions. Their nature, and their connection with the religious orders will be found explained in the article KNIGHTHOOD. Here we need only notice the list of the existing orders which either have survived the invention of gunpowder, to become, generally, marks of favour from the sovereign, who in almost all the orders is grand master, or which have been instituted since, to reward military or civil service or mark some person of distinguished merit.

AUSTRIA-HUNGARY.—The Order of the Golden Fleece (1429), second only in rank to the ‘Garter,’ will be found described at GOLDEN FLEECE.—St Stephen, instituted by Countess Elisabeth Theresa in 1766, is modelled originally as the supreme order of Hungary. It consists of the grand master (the sovereign of Hungary), twenty grand-cross knights, thirty commanders, and fifty knights. Badge, cross patté with red border, crimson ground, crowned, crossed by the Cross of the Holy Land.

Leopold, founded by Francis I. 1808, for ‘personal’ merit.—Elisabeth-Theresa, the second military order of the empire, founded by Empress Elizabeth Christina, 1735.—Order of the White Rose, founded in 1757 for ‘officers distinguished in war.’—Iron Crown, originally founded to commemorate the crowning of Napoleon I. as king of Italy in 1805, but revived by Francis II. 1836, and then made the military order of the Holy Roman Empire, which it is. It is given for personal merit only. The present badge is the Austrian eagle in gold, &c., raised from the iron crown and pendant from the imperial crown, with the inscription of the Community of Noble Ladies of the Starry Cross, an order for women instituted by the Empress Eleanor in 1683 to commemorate the miraculous preservation of a portion of the true cross. It is restricted to high-born ladies.—The Teutonic Order, of very ancient origin and uncertain origin, conferred on Roman Catholic noblemen and ladies who contribute to its ambulance fund.—Francis Joseph, instituted by that emperor in 1849 for distinguished merit in all classes.

BAYARD.—Several ancient orders. St Hubert was founded by Gerhard V., Count of Ravensberg, to commemorate his victory over Arnold, Count of Egmont, in 1444. It is the highest in the kingdom, and is confined to knights and cartes of the house of Bayard. It contains an order (1857).—Order of the Holy Land, 1254. The Maximilian Order, 1773. It is given for military merit, instituted by Maximilian Joseph in 1808; also confers nobility.—St Michael, an order for civil merit without distinction of rank or religion, founded by Joseph I. founded by Louis-le-Grand, 1276. The Maximilian Order, for art and science, founded in 1853 by Maximilian II. for Germans only.—Order of Military Merit (1865).—Royal Leopold Order (1827).—Order of the September Order of Maximilian Joseph in 1831. The Order of the Holy Land, 1254. It is given for military merit, instituted by Leopold I. (1825). It has five classes, of which the three inferior have pensions.—Iron Cross, for civil merit, founded by Leopold I. (1817).—St George, the Military order, instituted by Prince Alexander, in 1789.

BULGARIA.—The Military order, instituted by Prince Alexander, in 1789.

CHINA.—The Order of the Imperial Dragon was instituted in 1862 to reward foreigners who had done service to the empire, founded partly on the model of the British Order of the Bath, and headed by Sir Henry Pottinger, who was created Colonel (General) Gordon. It was put on a more permanent footing in 1882, and called the Order of the Black Dragon. It has five subdivided grades, most appropriately named 'worshippers, rulers, ruling princes, and imperial classes,' which are distinguished by different kinds of ‘pearls’ or hemispherical stones. It is this peculiar method of Chinese distinction which is irrevocably termed ‘buttons’ by foreigners.
DENMARK.—The Order of the Elephant claims to be as old as the First Crusade, but Christian V. in 1583 altered its statutes and gave it its present title. It is rarely given, and is valued in consequence, and has only one class of thirty knights, exclusive of princes of the blood. Badges are white and scarlet, divided into two unequal, intermingled, watered, light blue.—Order of the Dannebrog was said to have been instituted by Waldemar II. in 1210, to commemorate a miraculous intervention in a battle, but also received its present name from the court honour to an order of merit by Frederick VI. in 1898. It has five classes. Badge, an oblong Danish cross, enamelled white with red border. Ribbon, white with red edges.

France has allowed all its old chivalric orders to lapse, and has now only the Legion of Honour (q.v.), which has the advantage of being adapted to any form of government.

GERMANY. See the sections on Prussia, Bavaria, Saxony, and Wurttemberg.—Many of the minor German states also have orders, the principal of which are the following: Anhalt, Albert the Bear (1807), but clased in 1834; Brunswick, Henry the Lion (1834), military, civil, and science, etc. (1807); Hanover, the Order of the House of Philippo le Bon (1840), merit; Military Merit, (1870); Golden Lion (1770, revived 1870); Military Sanitary Cross (1750), for those, irrespective of rank or sex, who are wounded singly in the service; Crown of the Wends (1864) — it has five classes, the highest open to ladies of exalted rank, ninety-six members being appointed to Schwerin and thirty-two to Stolitz; Cross of Honor.—Schwerin, Order of the Crowns (1910); Order of the House of Peter Frederick Louis (1838), open to all distinguished in science, art, and domestic virtues.—Saxe-Gotha and Altenburg, Order of Saint Ernest (1825), composed of ten classes. Order of the Duceal House of Peter Frederick Louis (1838), open to all distinguished in science, art, and domestic virtues.—

GREAT BRITAIN.—The Most Noble Order of the Garter, which stands pre-eminent amongst the orders of knighthood in the British Empire, is the same as the Thistle (Scotland), St Patrick (Ireland), Bath, and St Michael and St George are all described under their respective titles. For the Orders of the Star of India, Indian Empire, and Order of India, see INDIA ORDERS.—Order of Victoria and Albert, instituted in 1892 by Queen Victoria for ladies. Badge, the heads of the Empress Queen and Prince Consort, surrounded by the crown of thorns, accompanied by the arms of the British Empire, with the harp of the Order of the Thistle, and the arms of Victoria and Albert. Ribbon, three colours: red, white, and blue.—

GREECE.—Order of the Redeemer, founded by King Otho in 1832 to commemorate the deliverance of Greece. Confirmed for distinction of all kinds.

ITALY.—Order of the Annunziata, the third in rank of all orders, claims to have been founded in 1362 by Amadeus VI, Count of Savoy. It was restored by Charles Albert in 1814, and was finally confirmed by Victor Emanuel II. in 1860, who restricted the knights to twenty, exclusive of the sovereign, foreign princes, and certain others. Badge, a gold medallion representing the hands of Christ, studded with diamonds, for wear by ladies. Ribbon, red border and white edges.—

St Maurice and St Lazarus, formed by the union of two distinct orders, the first dating from the 15th century, and the latter claiming to have been in existence in Jerusalem in 1501. After many changes, it was decreed new statutes by Victor Emanuel II., who made the number of knights unlimited.—Military Order of Savoy, instituted by Victor Emanuel I. in 1815, altered by Victor Emanuel II. in 1855. It has six classes.—Order of Savoy, instituted by King Charles Albert in 1831, limited to sixty knights, "who have contributed to the service of the king and the welfare of the state."—The Crown of Italy, instituted by Victor Emanuel II. in 1868 to commemorate the annexation of Venetia. The number of knights is practically unlimited.—Order of the Chivalry of San Marino was instituted by the grand council of the Republic in 1859.

JAPAN possesses two orders—The Eastern Sun, for civil, and Military, instituted in 1874; and the Order of the Chrysanthemum (1876), which the Mikado himself wears. It is mostly confined on princes of the blood and foreign sovereigns, the first foreigner to receive it being Carvalho-Fidalgo. It is divided into six classes, as yellow enamel chrysanthemum variously ornamented.

LUXEMBOURG has one order, the Oaken Crown, instituted for all classes by William II. of the Netherlands in 1841.

MONACO has the Order of St Charles (1858).—Montenegro has two orders—Danilo the First (1852), for civil merit; and St Peter (1852), for members of the reigning house exclusively.

NETHERLANDS.—The Order of William, founded by William I. in 1815, is to reward conspicuous military gallantry; and the Order of the Netherland Lion (1815) rewards civil merit. There is also the Order of the Golden Lion (1838) as a family order of the House of Nassau.

PERU.—The Order of the Sun and Lion, instituted in 1808; and the Order of the Sun (1873), for ladies.

PONTIFIC.—The Order of St Gregory the Great was established by Gregory VII. in 1073, for men and women; the Order of St Sylvester is for zeal in the cause of the Roman Catholic religion.—The Order of Christ, dating from 1319, is similar to the Portuguese order of the same name, except that noble birth is not requisite to its adoption. The badge of the St Sylvester claims a very early foundation, but seems to have really originated in 1559. Gregory XVI. in 1841 restricted its application to zeal in the cause of the church and ecclesiastics. The order of St Peter was founded in 1847 by Pius IX., and confers nobility. The Order of the Holy Sepulchre claims to date from 1099, and was confirmed by Benedict XIV. in 1746. Pius IX. added new statutes in 1873; and the Order of the Holy Sepulchre was founded in 1847 by Pius IX.—For the Order of St John of Jerusalem, see HOSPITALIERS.

PORTUGAL.—The military Order of St Benedict of Aviz originated in 1145 in a society of noble Portuguese for the purpose of opposing the Moors. It remained a military order until 1793, when Dona Maria converted it into an order of merit of three classes. Badge, a silver cross, enamelled green with golden edges.—The Distinguished Service Order (1886), "for rewarding individual instances of meritorious and distinguished services in war."

SCOTLAND.—Order of the Red Cross, founded by King Robert II. in 1307 for bravery in battle, and which is still used by the Scottish authorities. Ribbon, red, white, and blue.—The Order of the Thistle, created by King James II. of Scotland, for those of noble birth. Ribbon, red and blue.—The Order of the Thistle, created by King James II. of Scotland, for those of noble birth. Ribbon, red and blue.—

SPAIN.—Order of Alcantara, founded by Alphonso XIII in 1881; the badge is a crowned lion issuing from a chasuble.—Order of San Fernando, instituted in 1705, for meritorious service. Badge, a white shield, with the arms of Spain and Portugal, and the words "San Fernando de los Reyes".—Order of Santiago, founded in 1187 by Ferdinand and Isabella, for meritorious service. Badge, a golden cross, with the words "Dieu et mon droit," and the arms of Aragon and Castile. Ribbon, red and blue.—The Order of San Hermogenes, founded in 1872, for the preservation of the产值 and the order of merit. Badge, a white cross, with the words "San Hermogenes," and the arms of the Kingdom of Spain. Ribbon, red and blue.—

SWITZERLAND.—The Order of the Holy Ghost, for the propagation of the Catholic faith. Badge, a white cross, with the words "San Hermogenes," and the arms of the Kingdom of Spain. Ribbon, red and blue.—

UNITED STATES.—The Order of the Star Spangled Banner, for meritorious service. Badge, a gold star, with the words "San Hermogenes," and the arms of the Kingdom of Spain. Ribbon, red and blue.—

Vatican.—The Order of the Holy Sepulchre, established by the Pope in 1099, for the protection of the Holy Sepulchre. Ribbon, red and blue.—

WROCLAW.—The Order of the Faithful Subjects, founded by King Casimir the Third, for meritorious service. Badge, a golden cross, with the words "San Hermogenes," and the arms of the Kingdom of Poland. Ribbon, red and blue.—

YUGOSLAV.—The Order of the White Eagle, founded by King Peter I. in 1861, for meritorious service. Badge, a white eagle, with the words "San Hermogenes," and the arms of the Kingdom of Serbia. Ribbon, red and blue.—

ZAMBIA.—The Order of the White Star, founded by the President of Zambia in 1964, for meritorious service. Badge, a white star, with the words "San Hermogenes," and the arms of Zambia. Ribbon, red and blue.—

These are only a few of the many orders that exist in the world, each with its own unique history and significance. It is important to remember that these orders are not simply decorations; they are symbols of honor and recognition for those who have made significant contributions to society.
ORDERS OF KNIGHTHOOD OR CHIVALRY

Frederick-William III, which received a new constitution from Frederick-William IV. in 1822 (see HOSPITALERIEN).—Order of Civil Merit in arts and sciences was founded by Frederick-William IV. in honour of the memory of Frederick II.—Order of Louisia was founded in 1815 by Frederick-William III. for women's services in war.—Order of the House of Holstein-Sonderburg, founded in 1831. —Order of Military Merit, established by Prince Charles in 1827.—Order of the Crown of Roumania, founded in 1851 by the King of Roumania.

Russia, like Prussia, has no very ancient orders, though it has introduced the usual distinctions. The Order of Saint Andrew, the patron saint of Russia, founded in 1698 by Peter the Great, is the highest in the empire. It carries with it the orders of St Anne, Alexander Nevsky, and St Stanislaus, Barabas-headed ribbons, charged with St Andrew on an azure cross, and surrounded by the imperial crown.—Order of St Catherine, founded by Peter the Great in honour of his consort Catherine I. in 1725, is now restricted to ladies.—Order of Alexander Nevsky, instituted by Catherine I. in 1725 in honour of Alexander, son of Jaroslav, Prince of Novgorod (1240). It is both civil and military, the latter open to no one under the rank of major-general.—Order of St Anne, founded in 1735 by Duke Frederick Charles of Holstein-Gottory in memory of the Empress Anna, and declared a Russian order in 1794 by Paul III. —Order of St Stanislaus, founded by the Catherine I. in 1765, and Military Merit, by Stanislaus Augustus in 1792 and revived at Warsaw in 1807, were in 1831 united with those of Russia.

SAXON.—The Order of the Crown of Saxony was founded in 1657 by King Frederick Augustus, at the suggestion of Napoleon I.—Order of Albert the Valorous, for merit in science, art, and civil virtue, instituted by King John in 1830.—Order of St Henry, for merit on the battlefield, founded by Augustus III., King of Poland and Elector of Saxony in 1739.—Order of Civil Merit, founded in 1815 by King Frederick Augustus on his restoration.—Order of Saxon, for services to education, literature, or the church, was instituted in 1832.

SIAM.—The Royal Order of the White Elephant was instituted in 1861, and consists of five classes. It is the highest of Siamese orders, and was accepted by the Empress-Queen Victoria. Badge, a beautiful enamelled white elephant, surrounded by a triple circle of leaves in yellow, red, and green enamel, and surrounded by the Siamese crown.—The Order of the Crown, the second in Siam, instituted by the king of Siam in 1840.—Order of Chulalongkorn, founded in 1868 by King Chulalongkorn, said to have been instituted in 1781; and the Order of Maha Chakravadi, founded by the king of Siam in 1882 in honour of the centenary of his capital.

BRAZIL.—Prior to the establishment of a republic in 1890, had four orders:—Order of Pedro (1827); Order of the Southern Cross (1829); Order of the Rose (1829), all instituted by Dom Pedro I. Order of St Domingos of Ava, St James of the Sword, and of Christ, taken by the Brazilians when a dependency of Portugal, and proclaimed as 'national' in 1823.—Bolivia and Peru—Legion of Honour (1866).—Honduras—Santa Rosa (1829).—Nicaragua—Order of St John of Niegnancy (1837).—Venezuela—Order of the Bust of Bolivar (1825).

SPAIN.—The Order of Calatrava was instituted to commemorate the recovery of that town from the Moors in 1147. Convents of nuns were attached to the order in 1219 and in 1470. In 1523 Charles V. vested in the crown of Spain the grand mastership of the orders of Calatrava, Alcántara, and St James. Badge, a gold laurel and a red fleur-de-lis cross.—Order of St James of Compostella, founded to preserve the patron saint of Spain, believed to be preserved at Compostella. It is now purely military. Badge, a red enamel shield with fleur-de-lis in an oval white enamel shield, revolved red, by Frederick Motors (q.v.), instituted in 1777 by Pope Alexander III., but the name Alcantara was only assumed in 1213 on their getting possession of that place. Badge, same as Calatrava, but green. —Our Lady of the Rosary, founded by James II. of Aragon and Valencia.—The Golden Fleece, identical with the Austrian order of the same name (see GOLDEN FLEECE).—Order of Charles the Third.—Order of the Patriotic.—Order of Maria Luisa, founded by Charles IV. in 1792 for 'noble ladies.'—Order of St Hermengild, founded by Ferdinand VII. in 1814 for officers of the army and navy.—St Ferdinand, founded, by Ferdinand VII. in 1811 for military exploits, includes a class for subaltern officers and soldiers.—Isabella the Catholic, founded by Isabella of Portugal in 1815 for defence of the American possessions.—Buenos Aires, established by royal decree in 1856 for humane and useful public services.—Narval Merit founded on the 'Marine Cross' of 1816, in 1868.—Maria Isabella Luisa, instituted in 1853 to reward the lower grades of the army in honour of the king's 'august daughter.'—Military Merit, founded by Queen Maria Isabella Luisa in 1864.

SWEDEN AND NORWAY.—Order of the Seraphim, or Blue Ribbon, of doubtful origin, but assigned to King Charles XII. for services in 1718, revived in 1728 by Frederick Motors twenty-four Swedish and eight foreign knights, who must not be under rank of lieutenant-general.—Order of the Sword, or Yellow Ribbon, ascribed to Gustavus Vasa and revived by Frederik I. in 1718.—Order of the Pole Star, or Black Ribbon, founded in 1748 by Frederick I. for civil merit.—Order of Vasa, founded by Gustavianus III. on his coronation in 1770 to reward services in developing the national education of the country. It has been revived.

—Order of Charles the Thirtieth, founded by that monarch in 1811 for Freemasons of high degree. It has a red ribbon. This is memrable as the only knighthood into which the Freemasons can be admitted.—Order of St Olaf, founded by King Oscar in 1847 in memory of St Olaf, who in 1015 threw off the yoke of Denmark. It is open to the meritorious of all classes. Red ribbon with blue and white border.

TURKEY.—Order of the Nishan Medjidj, established by Sultan Abd-ul-Medjd in 1850 for good conduct in the Turkish service. It has five classes, the first having fifty and the last six thousand members, not including those of foreigner origin, who may receive an Nishan. It was instituted in 1862. It has four classes for services to the state, military and civil.—Nishan Shefakat, instituted in 1877 for ladies, to commemorate the 'Turkish Committe of Association Fund' under the auspices of Baroness Burdett-Coutts.

WURTENBERG.—Order of the Crown of Wurttemburg, formed in 1818 by the union of an older order with Frederick I.'s Order of Civil Merit of 1806. It confers personal nobility on civilians.—Order of Frederick, a military order founded by King William in 1818 in honour of his father.—Order of Military Merit, instituted in 1789 by Duke Charles Eugene.—Order of St George, founded by King Frederick in 1827. Charles X of France was in 1811 in honour of his queen, Olga, and is bestowed for special service in the field, for both sexes.

In addition there are many minor governments which have their own orders.—Hawaii, has one, Kamehameha (1845), Kalakaua (1874), and Kinehu (1885, the date uncertain).— Abyssinia, Cambodia, Liberia, Zanzibar, &c., have one each.

A complete account of all the orders, fully illustrated, with a short account of their origin, is found in Orders of Chivalry, by Major J. H. Lawrence-Archer (London, 1887), to which work we are indebted for much of our information. See also Ellis Ashmele, Institution of the Orders of Chivalry (1586); Clark, History of the Orders of Knighthood (1784); Hansen, The Orders of Europe (1806); Carlisle, Foreign Orders of Knighthood (1838); Niolsen, History of British Orders of Knighthood (1842); Sir Bernard Burke, Book of the Orders of Knighthood (1866).

Ordination. See Orders (Holy).

Ordnance. See Cannon, Firearms, Machine Gun, Mortar, &c.

Ordinance Survey. By this term is understood the various operations undertaken by the British government for preparing maps and plans of the whole kingdom and its parts, the term 'ordnance' being applied from the fact that during its earlier days the survey was carried out under the direction of the Master-General of the Ordnance. The idea of a general map of any portion of the country to be executed by the government was first proposed after the rebellion in 1745, when the want of any reliable map of the northern parts of Scotland was much felt by the officers in command of the royal troops. It was then entrusted to Lieutenant-General Watson, the deputy quartermaster of North Britain; but it was mostly carried out by Major-General Roy, an officer of engineers. The drawing, on a scale of 1 inch to the mile, was completed in 1753; but, in consequence of the war which ensued, it was not published till 1784, with the object of calculating the difference of longitude between the observatories of London and Paris. A base-line was measured by General Roy, R.E., on Houlsow Heath, from which started a series of triangles extending to Dover. This triangulation was connected with that carried out in France in 1786. The government, shortly afterwards decided on having, for military purposes, a general survey on the 1-inch scale of the United Kingdom, and the triangulation carried out by General Roy in the southern counties became the basis of the general triangulation. In 1794 the survey for the 1-inch map was begun, and the first sheet was published in 1801. As the series of principal triangles were extended westwards towards the Land's End, it was thought right to measure another base on Salisbury Plain in 1794; and two base-lines for verification were subsequently measured—one in 1801 at Misterton Carr, and the other in 1806 on Ruddick Marsh. Though first intended chiefly as a military map, the publication of the survey soon created a demand on the whole to the public for better maps, and surveyors were then hired to hasten its progress. This, however, was very slow, the map being at one time entirely suspended during the war in the beginning of the 19th century, and even the parts which were executed, having been done by contract, were found very inaccurate. In this condition the survey of England continued during the first quarter of the century, sometimes delayed by the government from motives of economy, at other times urged on by the county gentlemen, who wished the map either as a hunting-map or for the improvements.

In Scotland the principal triangulation was begun in 1809, but was discontinued in the following year, to enable the persons who had been employed there to carry forward the subordinate triangulation. The first minute of the Ordnance Survey in Scotland was drawn in 1815; but in 1818 the detail maps in England. In 1815 it was resumed, and continued steadily up to 1819; a new base-line having been measured on Belhelvie Links, near Aberdeen, in 1817, and the great sector used at various stations, both on the mainland and on the islands. In 1820 it was again suspended, was resumed in 1821 and 1822, and anew broken off in 1823, the large theodolite being wanted in order to proceed with the principal triangulation in South Britain. In 1824 the survey of Ireland was begun, and nothing more was done in Scotland till 1838, except that some detail surveying for a 1-inch map was continued for a few years in the southern counties. The chief strength of the surveying corps was transferred to a triangulation map of that country was required for the purpose of making a valuation which should form the basis of certain fiscal arrangements and other improvements which the social evils and anomalies of Ireland urgently demanded. For this map a scale of 6 inches to a mile was adopted, as best suited for the purposes in view. On this scale the whole map was completed, and published in 1845, though the first portions were in an imperfect form, and needing revision, which was proceeded with in 1873. The triangulation of Scotland was resumed in 1838, and in 1852 the whole of the primary triangulation of the United Kingdom was completed. It comprises, in all, 230 trigonometrical stations, and the average length of the sides of the triangles is 35-4 miles, the longest being that from Seafield to Helensburgh. During the triangulation of Ireland a base-line had been measured on the border of Lough Foyle. As a test on the general accuracy of the triangulation the length of this base was afterwards calculated through the series of triangles from the base on the Irish side, and was found to be 1826-9 miles, the measured base by only a little more than 5 inches. The distance apart of these two bases is about 360 miles, and their length about 41,641 and 36,575 feet respectively.

The survey of Ireland having been finished in 1840, surveys for a 1-inch map were begun for the northern portions of England which had not been previously mapped on the 1-inch scale. In 1841 some secondary operations for a map of Scotland, also on a 6-inch scale, were begun, but proceeded so slowly that in 1850 only the map of Wigtownshire and some parts of Lanarkshire were completed. Much dissatisfaction having been expressed in Scotland by the press and public bodies as to the slow progress of the map and the 6-inch scale on which it only was published, a committee of the House of Commons (Lord Eldon's committee) was appointed in 1851 the 6-inch maps to be stopped, and the 1-inch map completed as speedily as possible. This change produced much discussion as to the relative value of the 1-inch and 6-inch scales then in use, and the expediency of adopting a still larger scale as more suitable to the purposes of the map. Many letters were issued, asking the opinion of various public bodies, and of scientific and practical men, as to the proper scale for a great national survey. The great preponderance of opinion was in favour of a scale of $\sqrt{\pi}$ of nature, or nearly 1 inch to the acre. This scale was therefore ordered by a treasury minute of 18th May 1855 (Lord Palmerston's), and though subsequently stopped, in consequence of a motion by Sir Denhain Norreys in the House of Commons in June 1857, was again recommenced by a royal commission (December 1857), and ordered to be resumed by another treasury minute (11th September 1858). In 1861 a select committee was again appointed, and reported that it is desirable that the cadastral survey on the scales directed by the treasury 1855, 1857, and 1858, be continued for all the principal portions of the United Kingdom that have been surveyed on the scale of 1 inch to the mile only. This recommendation was presently adopted by the government, and the survey has been completed on the following scales: Towns having 4000 or more inhabitants are surveyed on a scale of $\frac{1}{2}$ of the linear measurement, equal to 2534 inches to a mile, or one square inch to an acre; counties
on a scale of 6 inches to a mile; kingdom, a
general map 1 inch to a mile.

The sheets of the 1-inch map join together, so
as to form a complete map of the whole kingdom.
This is true also of the sheets on the 6-inch and
T\textsuperscript{1/2} inches; but it is not so with the
different counties, except when drawn to the same
meridian, are not connected. The T\textsuperscript{1/2} scale
also applies only to cultivated, populous, and
mineral districts; the Highlands of Scotland, and
other extensive moorland and uncultivated tracts,
being surveyed on the 6-inch scale, have a less vivid
appearance.

The scale, originally 1 inch to a mile, was
increased to 6 inches to a mile when the survey
reached Yorkshire and Lancashire; these counties
being done on that scale as well as on the 1-inch
scale. The remaining counties of England were
done on the scale of 25 inches to a mile for culti-
vated districts, and on 6 inches to the mile for the
uncultivated and moorland districts. When Eng-
land was completed a re-survey was begun on the
25-inch scale of those counties which had only been
surveyed on the 1-inch scale. The sheets on the
scale of 1 inch to a mile (called parish maps) are
reduced by photography, and issued on the
scale of 6 inches to a mile (county maps). The
1-inch maps are again reduced by photography
from the 6-inch, and are being published in outline
only and also with hills.—The survey of the whole
of Scotland was completed in 1863, and the maps
for the whole area, on either the 25-inch or 6-inch
scales, have been published. On the 1-inch scale
two editions are published, one in outline only and
another with hills.—In Ireland, as stated, the
6-inch maps have been long published, and are
now in a process of revision; the survey on the
25-inch scale has been commenced. A 1-inch map
of the whole in outline, and, with the exception
of a few sheets, an edition with hills have been
published. In all the three kingdoms plans of
most of the towns on the 10 and 5 feet scale are
also published.

The sketch now given of the history of this
great national undertaking will show that it has
been conducted at different times on different
scales and plans, and that the system now pursued
was only adopted after much discussion both in public
and in private. It is to be observed that the
work was originally begun as a military map, and the scale
of 1 inch to the mile chosen, without considering
whether some other scale would not offer greater
advantages. Many now think that a scale a little
larger, and an aliquot part of nature, such as
\( \frac{25}{6} \) inches, would have been preferable for the small map; in which case
a scale of \( \frac{25}{6} \) inches, or about 63 inches,
might have been chosen for the intermediate,
instead of the 6-inch scale selected at first for
more local purposes in Ireland. Be this as it may,
the experience in favour of the 6-inch map is
that it is the most convenient both as a general and
travelling map. For general views of the
structure of a country, the distribution and rela-
tions of its mountains, plains, valleys, and rivers,
the scale of 1 inch to the mile is admitted to be superior to the 6-inch,
and, as is more adapted in the first instance for
laying out roads, railways, or other extensive public
works, or for the publication of a general geological
survey. Such a map, on the other hand, is too
small a scale to admit of correct measurements of
men, buildings, and roads, and is in some parts a
generalised picture and not a correct plan. The 6-inch maps
were at first selected in Ireland as the smallest size
on which correct measurements of distances and
areas could be made. On them every house and
field, and almost every tree or bush, might be laid
down. They are superior first working out details, as in minute surveys of railways or roads,
or the complex geological structure of rich mineral
districts. On such sheets, too, a proprietor or
farmer may find every field laid down, and the
relative heights indicated by contour lines, and
may therefore use them for drainage and other
improvements. It is more advantageous also to
possess a correct map of the physical features of a country than the hill
sketching of the 1-inch map. Most of the pur-
purposes of the 6-inch plans are attained in a still
more perfect manner from the 25-inch plans or
cadastral survey. This last name is taken from the French cadastrer ("a register of lands"), and is
defined (in the Recueil des Lois, &c.) as a plan
from which the area of land may be computed,
and from which its revenue may be valued. The
purposes to which these large plans may be applied
are as estate plans, for managing, draining, and
other purposes; improvements may be made or
controlled by registering sales or encumbrances; and as
public maps, according to which local or general
taxes may be raised, and roads, railways, canals,
and other public works laid out and executed. In
1870 the Ordnance Survey was transferred from the
Geodetic Survey to the Office of the Survey of
Works, and in 1890 to the newly-instituted Board of
Agriculture.

Nearly all civilised states have produced trigono-
metrical surveys, many of them of great excellence
as scientific works. The most important are:

- Austria, \( \frac{25}{6} \) inches to a mile.
- Belgium, \( \frac{25}{6} \) inches to a mile.
- Denmark, \( \frac{25}{6} \) inches to a mile.
- France, \( \frac{25}{6} \) inches to a mile, and a reduced map,
  \( \frac{25}{6} \) inches to a mile.
- Germany, \( \frac{25}{6} \) inches to a mile; also \( \frac{25}{6} \) inches to a mile.
- Italy, \( \frac{25}{6} \) inches to a mile; also \( \frac{25}{6} \) inches to a mile.
- Netherlands, \( \frac{25}{6} \) inches to a mile.
- Norway and Sweden, \( \frac{25}{6} \) inches to a mile.
- Switzerland, \( \frac{25}{6} \) inches to a mile.
- United States, \( \frac{25}{6} \) inches to a mile, to \( \frac{25}{6} \) inches to a mile.
- Drift surveys.

The Coast and Geodetic Survey of the United
States, which was authorised in 1807, but not
really begun till 1817, is a work of enormous ex-
tent, great accuracy, and minute detail. The full
organisation of the survey was mainly due to A. D.
Iachet (q.v.). The general chart was published
on a scale of \( \frac{25}{6} \) inches to a mile; the
harbours and ports \( \frac{25}{6} \) or \( \frac{25}{6} \) of an inch to a mile.
A vastly greater undertaking, the triangulation of
the whole area of the republic, has been more
recently begun. The great Trigonometrical Survey
of India was commenced in 1832; and the year
1889-91 witnessed the completion of the principal
triangulation of all India. The maps are published
on various scales, those of the Trigonometrical
Survey being on a scale of \( \frac{25}{6} \) or 25 inches to a mile,
while maps on both larger and smaller
scales are published for revenue and special pur-
purposes.

The Geological Survey of the United Kingdom,
though under a different department of government
(Science and Art), may be shortly noticed here. The
English survey, begun in 1832, was completed
(till theIntroduced"), 25 inches to a mile (solid geology), and
the Drift survey proceeded with. The Irish
survey was begun in 1840, but was subsequently suspended
1845. It was completed in 1887, and the whole
of the maps are now published. In 1854 the survey
was extended to Scotland. The southern half of the
country has been completed, and the mapping in the
Highlands is now in progress. The surveys
ORDOVICIAN

Oregon, a name sometimes given to a geological formation intermediate between Cambrian and Silurian; otherwise accounted the Lower Silurian strata. It is so called from the Ordovices, an ancient British tribe.

Ore-deposits. Any mineral which is obtained by mining, and which contains a workable proportion of a metal, is called by miners an ore. Ore-deposits in general are forms and positions in the earth's crust. Sometines they are found in gravel, sand, and other alluvial deposits. Examples of this class are afforded by the placer deposits of California (see Gold), the now exhausted tin-stream works of Cornwall, and the bog iron ores of various countries. In other cases the ores occur disseminated through igneous and sedimentary rocks. Tin ore and magnetic iron ore are frequently met with in this form. When the whole rock is permeated with mineral matter, accumulated in minute veins, the deposit is termed a stock-shear. Examples of such deposits of tin ore occur at Carlisle and other places in Cornwall, and at Altenberg in Saxony. Again, the ores may occur in detached masses. Such, for instance, are the red hematite deposits of Ulverston in Lancashire, the brown hematite of the Peak of Dean, the iron mountains of Gotha and Tauber in Sweden, and of Missouri. The ores may occur in regular parallel beds (see mining) or seams interpolated between rocks of sedimentary origin, as in the case of the ironstone of the coal-measures, and in that of the iron ores of Cornwall and of Prussia. In Saxony, a seam not more than 5 inches thick which has been worked without interruption since the 12th century. Lastly, ores are met with in tabular masses, known as mineral veins or lodes, differing in character from the enclosing rocks. The simplest classification of ore-deposits is that based on their form, into two divisions: (1) tabular deposits, a class subdivided into (a) beds, whether interstratified or superficial, and (b) lodes; and (2) non-tabular deposits, or masses.

A lode is usually defined as a repository of minerals that is worked as a whole, whether more or less completely a former fissure. Though this definition is undoubtedly true in most cases, deposits are occasionally met with in which the rock at the sides of the fissure, having been so altered as to render it worth working as a fissure, is worked as the lode. These exceptional cases are included in a more general definition propounded by Dr C. Le Neve Foster, who regards lodes as tabular deposits of mineral, which have been formed subsequently to the rocks by which they are surrounded. Lodes are strata in mountainous districts, their thickness ranging from a few inches to 150 feet or more. Their longitudinal extent is equally variable. The great Mother Lode of California has been traced for a distance of 70 miles.

In tabular deposits, whether beds or lodes, two dimensions predominate, and the third or smallest dimension, the perpendicular distance between the two bounding planes, is termed the thickness. The adjacent rock on both sides of these two planes is termed the country-rock. The strike of a deposit is the line perpendicular to the dip of the deposit, and that covering it is the hanging-wall. With beds or seams, these are known as the floor or roof respectively. The strike of a deposit is the angle formed by the membrane by the direct line drawn in the middle plane, and its dip is the angle measured towards the horizon. As the dip of lodes is usually considerable, it is sometimes measured from the vertical, and is then termed under- or hade. The portion of a mineral deposit occurring at the surface is known as the outcrop, base, or (in the United States) opex. The contents of lodes vary, some parts containing worthless vein-matter or gangue, others being filled with ore. The productive portions are termed courses, bunches, shoots (U.S. cloutes), or pipes of ore. Cross-courses are veins in a direction nearly at right angles to the chief lodes of any particular mining district. Experience shows that the productiveness of lodes is affected by intersection with other veins, by the veins of the adjacent rock, and by changes of dip or of strike.

The ore-deposit subject is a much debated subject which has long occupied the attention of geologists. All the theories which have at various times been brought forward assume in the first place that a fissure has been formed in the earth's crust. This fissure has, it is thought, been filled up by mechanical action causing the attrition of the sides, by sublimation, by injection of molten or plastic material from below, as in the case of dykes of eruptive rock, or, lastly, by deposits of solution, coming from above, from below, or from the sides. The first mentioned, known as the lateral secretion theory, has received great support by the researches of Prof. F. Sandberger. These researches have shown the presence of the common heavy metals in rocks belonging to every geological period, Copper, tin, lead, zinc, cobalt, and nickel have been disseminated in direction nearly at right angles to the chief lodes of any particular mining district. Prof. Sandberger therefore concludes that these metals have been dissolved out and deposited in fissures. The subject of mineral deposits is systematically treated in Dr. A. A. LeNeve Foster's "Vein-Deposits" (Lund., 1884), in which a full bibliography of the subject will be found. The reduction of ores is discussed under Metallurgy, and under the names of the several metals.

Oregon, a Pacific state of the American Union, bounded N. by Washington, E. by Idaho, S. California and Nevada, and W. by the Pacific. Lat. 42°—45°, long. 116° 40'—124° 45' W. Area, 96,030 sq. m., or almost twice that of England. Oregon on the west is literally rock-bound by the Coast Range of mountains, having, between numerous indentations which furnish good harbours for sea-going vessels. The Columbia River affords the largest and deepest entrance. Seventy miles east of the Coast Range is the Cascade Range, the summits of the higher peaks being at almost regular intervals surmounted by snow-capped peaks of nearly double that altitude. From the Cascade Range eastward to the Blue Mountains, about 70 miles, and farther on to the eastern boundary of the state, the surface is diversified by many valleys and by low hills, with plains and terraces. Here the soil and climate are suitable for agriculture and grazing. In Western Oregon is the Willamette valley, 130 miles long and 60 miles

635
OREGON

wides, every foot of which is arable and fertile—
adapted by soil and climate to grain and fruit.

The valley is situated between the Coast Range and the Cascade Range of mountains. South of this are the Umqua and Rogue River valleys, both of which are large and contain fruits.

The climate of Oregon is mild, in spite of its northerly situation, owing first to the oceanic cur-
rent from Japan, which, starting with a tempera-
ture of 90°, is from 49° to 54° off the coast here.
Moreover, the cold Arctic winds are warded off by the Cascade Range, and no frost is found across the Rocky Mountains. The range of temperature from
summer to winter is small. On the coast the climate is mild and varies little, but there is fog in summer and excessive rain in winter; in the Willamette valley the summers are pleasant, the winters wet, and spring and autumn foggy in the mornings; the Umqua valley has a delightful climate, with some snow in winter; and the same, with greater heat and cold, is true of the Rogue River valley, the lake region in the south-east, and Eastern Oregon, where there is a good deal of snowfall. In general, the temperature varies from 50° F., the rainfall 36 inches—17 at Linnville, in the interior, and 59 at Astoria, on the coast.

The grain-crops of Oregon are wheat, oats, barley, rye, and maize, in this order. Flaxseed, hay, potatoes, tobacco, and hops (principally along the rivers Willamette and McKenzie) are also raised. From three to four million pounds of butter and cheese are produced annually. Great quantities of fruit, both green and dried, are annually shipped from the state, especially from the western districts; but in Eastern Oregon, too, except along the coast, and which succedan-

s what else is fast disappearing, and the herds of cattle are diminishing; agricultural and horticultural pursuits are receiving more attention. The farms best suited for fruit-farming are mainly limited to the valleys and foot-hills; but these are of vast extent, and the extreme richness of the soil and the mild-
ness of the climate make the state's productive powers almost inconceivably great. The demand abroad for Oregon fruits more than doubled annu-
ally from 1835 to 1890. The most successful fruits are the Italian prunes, apples (Oregon is called 'the land of apples' by the inhabitants), pears, apricots, and cherries (the Royal Ann cherries grow too large for one bite). The wealth of Oregon in timber is remarkable. The Oregon Pacific Railroad, in crossing the Cascade Range, passes through a great timber belt extending for 90 continuous miles; and it is stated that careful examination shows in one locality enough timber on one square mile to supply for twenty years a mill cutting 150,000 feet a day.

Among the other industries of Oregon may be mentioned the catching and tinning of salmon (400,000 cases were shipped from the Columbia River in 1890), the rearing of sheep (Eastern Oregon produces large quantities of wool of good quality), and mining. The minerals of the state comprise coal (29,600 tons in 1885), iron ore, gold (14,965 ounces), copper, nickel, quicksilver, fire-
clay, chroma, silver, manganese, zinc, lead, and platinum. Trade is facilitated by numerous lines of railway, and the navigable rivers have steamers running all the year. In 1891 there were three through lines connecting Oregon with the east and
south, and another was in construction.
The territory of Oregon was formerly included all the land between the Rocky Mountains and the Pacific Ocean north of 42° N. lat. John Jacob Astor established Astoria (q.e.) in 1811; in 1813 it was sold to the North-Western Fur Company, and it afterwards passed into the possession of the Hudson Bay Company. Great Britain's claim to

the territory was based on Drake's discovery of
the coast in 1579, Cook's visit to Juan de Fuca
Strait in 1778, the explorations of Captain John Meares in 1788-90, and Vancouver's survey of
the entire coast from 30° to 60° N. lat., and discov-
ered the Columbia River, in 1792. A treaty of joint occupation was agreed to between

British and the United States in 1818, and endured until 1846. Settlement by the New Engländers began in 1832, and an Indian mission was planted at Salem by the Methodists in 1834. The Oregon question was a prominent one at the presidential contest in 1844. In 1846 the dispute was
promised, the boundary line with British America being fixed at 49° N. lat. Oregon became a terri-

ory in 1848, and, with reduced limits, a state in
1859. It has thirty-three counties, and sends two representatives to Congress. The judges of the supreme court are elected by popular vote. The valuation of property in 1898 was $133,533,571.

The public school system consists of district
schools (3073 teachers in 1898, with an average daily attendance of 61,234) free to all between
the ages of 6 and 18. The University of Oregon, at Eugene, the state agricultural college at Corvallis,
and four normal schools, besides institutions for
the blind, deaf and dumb, and orphans. There are also thirty-three private and denominational
institutions. The principal cities are Portland
(pop. 1890, 90,436), Salem, the capital (pop. 1890,
30,465; (1890) 174,768; (1890) 313,767; (1900) 413,536).

Oregon River. See COLUMBIA.

ORENburg.

ORENburg, a town of European Russia, stands on the river Ural, by rail 727 miles ESE. of Moscow. Founded (1743) as a frontier fortress, it is now of importance for its commerce only; it imports cotton, silk-stuffs, cattle, hides, &c. from Bokhara, Khiva, and Tashkend. Its chief

industries are metal-working, sugar, and woollen goods. The
town possesses an arsenal and two military schools. Pop. (1832) 42,123.—The government has an area of 73,749 sq. m., and a pop. of 1,188,360, of very mixed races. Prague (246,000) and Cessacks (229,000) predominating.

Orense, capital of a Galician province of Spain, near the frontier of Portugal, on the left bank of the Minho, and 60 miles from its mouth. It has hot sulphurous springs, and manufactures woollens, linens, and chocolate. Pop. 13,291.

Oriental, name of trees of the natural order Lauraceae, sometimes called Mountain Laurel. O. opifera is a native of the countries on the lower part of the Amazon. A volatile oil obtained from the bark is used as a liniment, and when kept for a short time deposits a great quantity of camphor. O. capularia is a very large tree with strong-scented wood, the bark of which yields the cinnamon of Mauritius. It grows also in Bourbon and Madagascar. O. fiesens, a native of the Canaries, has wood (Til-wood) of a most disagreeable odour. O. bullata, found at the Cape of Good Hope, is also remarkable for its fragrant and rarefied odour of its wood, the Stink-wood of the colonists; but it is hard, durable, beautiful, takes an excellent polish, and is used in shipbuilding.

Oredontes, an extinct family of ungulates, the remains of which occur in the tertiary deposits of North America.

Orestes, a son of Agamemnon and Clytemnestra. When his father was murdered by his mother and her paramour Aegisthus he was saved by his sister Electra, who sent him secretly to Phocis to the court of Strophius, husband of Agamemnon's sister. Here he formed a romantic friendship with the king's son, Pyrules, and as long as he lived and grown up the pair went secretly to Argus, and slew Clytemnestra and Aegisthus. Madness seized him after the matricide, and he fled from land to land, ever haunted by the avenging Erinyes or Furies. At Athens, whither he had fled by advice of Apollo, he was purged of guilt by the Areopagus. Learning from Apollo, according to another story, that he could only recover from his madness by carrying off the statue of Artemis from the Tauric Chersonesus, he journeyed thither along with Pyrules, but the friends were separated by the death of the latter. Her priestess Iphigenia recognised her brother in Orestes, and all three escaped together, carrying the statue with them. Orestes recovered his father's kingdom at Mycenae, slew Neopolemus, and married his wife Hermione, who had been formerly promised to himself. The story of Orestes afforded a favourite theme to the great tragedians,—to Aeschylus in the extant trilogy, the Orestes; to Sophocles in his Electra; to Euripides in his Orestes and Electra. See Becker, Die Orestes-ange der Griechen (1838).

Orra. See ELESSA.

Orbina, Mathieu Joseph Bonaventure, founder of the science of toxicology, was born at Mahon in Minorca, 24th April 1787, and studied at Valencia, Barcelona, and Paris (whether he was sent by the junta of his province). In October 1811 he received the degree of Doctor of Medicine, and immediately commenced a private course of lectures on chemistry, botany, and anatomy, which was largely attended, and, along with his successful practice, soon rendered him famous. In 1813 appeared the first edition of his celebrated work on poisons, entitled Traité de Toxicologie Générale (Paris). In 1819 he was created a citizen of France, and became professor of Jurisprudence; and in 1823 he was transferred to the chair of Chemistry, to which in 1831 was added the deanship of the faculty. On the outbreak of the revolution of 1848 he was deprived of his place in the medical faculty on account of his conservative opinions, but retained his professorship. He died at Paris, March 12, 1853. Among other works he wrote on medical chemistry (1817) and on forensic medicine (1825). He also contributed largely to various journals, dictionaries, and encyclopedias.

Orford. See WALEPOLE.

Organ (Gr. organon, 'an instrument'), a musical instrument played by keys, and generally also by pedals, and consisting of metal and wood pipes, which sound by wind stored in bellows, and admitted into them at will. The following description is necessitated by the restricted character of the most essential arrangements of this very complicated instrument. As met with in cathedrals and large churches, the organ comprises four or sometimes five departments, each in most respects a separate instrument with its own mechanism, called respectively the great-organ, the choir-organ, the swell-organ, the pedal-organ, and sometimes the solo-organ. Each has its own keyboard, but the different keyboards are brought into juxtaposition, so as to be under the control of one performer. Keyboards played by the hands are called manuals; by the feet, pedals. The wind is conveyed to the organ by means of the stop or register, which, when depressed, opens a valve which supplies wind to the groove belonging to it. The various pipes of each key stand in a line directly above its groove, and the upper surface of the groove is perforated with holes bored upwards to them. Were this the whole of the organ mechanism, the wind on entering any groove would penetrate all the pipes of that groove; there is, however, in the upper board another series of horizontal grooves at right angles to those beneath, supplied with cross-slides, which can be drawn out or pushed in at pleasure by a mechanism worked by the draw-stops placed within the player's reach. Each slide is perforated with holes, which, when it is drawn out, complete the communication between the wind-chest and the pipes: the communication with the pipes immediately above and below being, on the other hand, closed up when the slide is pushed in. The pipes above each slide form a continuous set of one particular quality, and each set of pipes is called a stop. Each department of the organ is supplied with a number of stops, producing sounds of different quality. The great-organ, one of whose pipes appear as show-pipes in front of the instrument, contains the main body and force of the organ. Behind it stands the choir-organ, whose tones are less powerful, and more fitted to accompany the voice. Above the choir-organ is the swell-organ, whose pipes are enclosed in a wooden box with a front of louvre-boards like Venetian blinds, which may be made to open and shut by a pedal, with a view of producing crescendo and diminuendo effects. The pedal-organ is sometimes placed in an entire space behind the choir-organ, and sometimes divided and
a part arranged on each side. The most usual compass of the manuals is from C on the second line below the ledger line to F above the third ledger line over the treble staff; and the compass of the pedals is from the same C to the F between the bass and treble staves—i.e. two octaves and a half. The real compass of notes is, as will be seen, much greater.

Organs vary much in form and material, but belong to two great classes, known as **flue-pipes** and **reed-pipes**. A section of one of the former is represented in the figure. Its essential parts are the foot a, the body b, and a flat plate c, called the language, extending nearly across the front of the instrument at the point of junction of foot and body. There is an opening, d, in the pipe, at the spot where the language is discontinuous. The wind admitted into the foot rushes through the narrow slit at d, and, in impinging against c, imparts a vibratory motion to the column of air in the pipe, the result of which is a musical note, dependent for its pitch on the length of that column of air, and consequently on the length of the body of the pipe: by doubling the length of the pipe we obtain a note of half the pitch, or lower by an octave. Such is the general principle of all flue-pipes, whether of wood or of metal, subject to considerable diversities of detail. Metal pipes have generally a cylindrical section, wooden pipes a square or oblong section. A flue pipe may be stopped at the bottom by a stop of the kind called a **toupeon**; the effect of which is to lower the pitch an octave, the vibrating column of air being doubled in length, as it has to traverse the pipe twice before making its exit. Pipes are sometimes half-stopped, having a kind of chimney at the top. The **reed-pipe** consists of a reed placed inside a metallic pipe. This reed is a tube of metal, with the front part cut away, and a tongue or spring put in its place. The lower end of the tongue is free, the upper end attached to the top of the reed; by the admission of air into the pipe the reed is made to vibrate, and, in striking either the edge of the reed or the air, produces a musical note, dependent for its pitch on the length of the tongue, its quality being determined to a great extent by the length and form of the pipe or bell within which the reed is placed. When the vibrating tongue does not strike the edge of the reed, but the air, we have what is called the **open-reed** or **free-reed**, similar to what is in use in the Harmonium (q.v.).

To describe the pitch of an organ-pipe terms are used derived from the standard length of an open flue-pipe of that pitch. The largest pipe in use is the 32-feet C, which is an octave below the lowest C of the modern pianoforte. There is, however, now in the new Sydney organ a pedal stop 61-feet tone. By a 32-feet or 16-feet stop we mean one whose lowest note is produced by a pipe 32 feet or 16 feet in length.

The organ does not always produce the note properly belonging to the key struck; sometimes they give a note an octave, or, in the pedal-organ, even two octaves lower, and sometimes one of the harmonics higher in pitch. **Compound or mixture stops** have several pipes to each key, corresponding harmonics being derived from the whole compass of the keyboard. The stops on an organ are principally of 8 feet in the manuals, the **dulciana** is an 8-feet manual stop, of small diameter, so called from the sweetness of its tone.

Among the reed-stops are the clarion, oboe, bassoon, vez humana, *trumpet or piano*, and *trumbone or pipe batahida*.* Among the reed-pipes are the so-called *organs represented the said performances of the Harmonium, and the organ in the church of St. George. The organ of St. George is of a different order. The resonators are more of a square than of a cylindrical form, and consist of a number of chambers or mouths, each with a tube attached, arranged in sets. These are used for the vocal music, being small organs of the natural scale. The stop names are derived from the French, and are very varied and peculiar. The organ pipes are arranged in departments and classes, each having a name; the whole compass of the keyboard is divided into twelve main departments, each of which is subdivided into classes of pipes of equal size or tone.
ORGAN-METALLIC substances, discussed in the paper by Peter's Haarlem whose Carbon, Zinc-methyl, and Swell point to the hotch-potch of organ-building, and himself no mean inventor in the art.

The family of the Antiquitati, in Brescia, had a great name as organ-builders in the 15th and 16th centuries. The organs of England were once in high repute through the work of such masters as Kilpin. These organs were of almost every description, from the largest to the smallest, and all the intermediate sizes, down to the smallest of the metals whereof the pipes were made. Those diminutive organs, called regals, so small that they could be held on the palm of the hand, were the outcome of monastic ingenuity, and Pope Sylvester II. was a warm patron of organ-building, and himself no mean inventor in the art.

For the structure of the organ, see Hopkins and Rimbaud, The Organ (Lon. 1856). For the history of the organ, see Kowboihan's History of Music, vol. iii. chaps. 5-6, and book iv. chap. 2 (Lond. 1887). For organ-playing, see Arentz, Manual of Organ Playing, and the Organ, Stainer's The Organ. There are also works on the organ by Warman (1882-87) and Elliston (1894), and a very full organ bibliography in Notes and Queries for 1902-03. The organ as an organ in Musicalium; and Barrel-organ is a separate article.

Organ. Organic, Organism, terms derived from the Greek organon, 'an instrument,' and still retaining in some of their applications that significance. But the words have found special acceptance in connection with the phenomena of life; Linnaeus described these, whether animals or plants, as Organista; and we constantly speak of them as organisms, of their larger, well-defined, and integrated parts as organs, of their internal activity and its products as organic. Prior to the year 1828 it was believed that certain chemical compounds which were produced as the result of vital processes occurring within the tissues of animal and vegetable organisms could not be obtained by the ordinary methods of the chemical laboratory; and these compounds were, for this reason, designated as organic. Without, in that year, however, did it appear that there was the most important solid constituent of urine, could be obtained "artificially," as it has been called, from inorganic materials. Since that date a very large number of so-called organic compounds have been synthesized and classified as "artificial" or "organic." The significance of the term 'organic' does not hold any longer; and the old conception of an organism as an engine-like collection of organs with fixed functions, is disappearing before the doctrine that it is the proteidism or living stuff in all parts of the body that is the basis of all vital activities. The title of organic chemistry is now commonly applied to the chemistry of the compounds of carbon, whether these compounds are obtainable only as the products of vital processes or not; see the articles CHEMISTRY and ANALYSIS (Organic). Organic indicators, white in water, are those due to the influence of animalcules, bacteria, and decomposing organisms; while such phrases as 'organic disease,' 'organic connection,' refer to the relation between a living organism and its parts. See BIOLOGY, FUNCTION, MORPHOLOGY, PHYSIOLOGY.—For organic bases, seeALKALIS; for organic radicals, see RADICALS.

Organ-metallic Bodies. Under this term are included a large number of chemical compounds in which organic radicals, such as methyl, CH₃, ethyl, C₂H₅, &c., are united to metals. Amongst the earliest obtained of these substances were those derived from the metal zinc. Zine-methyl, Zn(CH₃)₂, is a methylated zinc, and may be taken as examples of the class, are colourless liquids, heavier than water, which boil at 46° and
118° C. respectively. They take fire spontaneously in contact with air, and burn with the production of a dense white smoke of oxide of zinc. In contact with the skin they give rise to severe wounds which are very difficult to heal. They are decomposed with great energy by water. Substances analogous to these zinc compounds have been prepared, containing endiumium, magnesium, antimony, arsenic, bismuth, tin, aluminium, mercury, lead, sodium, potassium, and some rare metals.

For further information on this subject, see an article by Dr. Frankland, in the 13th vol. of the Quarterly Journ. of the Chemical Soc. Also the article on 'Organic Chemistry of the Bodies' in Wats's Dict. of Chemistry: or any of the larger works on the elementary principles of organic chemistry.

Organise. See STL.

Orgies, secret rites or customs connected with the worship of some of the pagan deities; as the secret worship of Demeter, and the festival of Dionysus, which was accompanied with many customs of mystic symbolism, and much license. From this latter rite, which is supposed to mark the modern sense of drunkenness and debauchery implicit in the word. See MYSTERIES.

Oribusius, a Greek medical author, and physician to Julian the Apostle (326-403 A.D.). He was born at Pergamum or Sardis, and his works are largely compilations from Galen (see MEDICINE, p. 171). There is an edition of his works in 9 vols. by J. Diderot (Darmstadt, 1852-79).

Oriell Movement. See KEBLE, Newman.

Oriell Window, a projecting window in an upper story, supported on corbels, having more sides than one, usually three, and commonly divided into bays by mullions. It is one of the most picturesque features in medieval and Elizabethan domes and arches, and adds much to the convenience of the interior. The word oriell (Mid. Lat. orielum, probably dim. from or, orts, as if a small opening or recess) formerly meant a chamber or apartment, and a window is so called which makes, as it were, a small apartment off a large room. By old writers oriels are called Bay Windows (q.v.).

Orthostats, in Architecture, is the position of a church so that its chancel shall point towards the east. This was a fashion invariably adopted in northern countries, but not adhered to in Italy and the south. St. Peter's at Rome, for example, has the chancel to the west, and the principal entrance to the east. The orientation of churches is not usually very exactly to the east, and it is supposed that the east end in some cases has been set so as to point towards the place where the sun rises on the morning of the patron saint's day. In other cases the choir and nave are not built exactly in a straight line, the choir having thus a slight inclination to one side, which in the symbolism of the middle ages was supposed to indicate the bowing of our Saviour's head upon the cross. This departure from the line of the true east, however, in many instances arose more probably from carelessness or ignorance.

Oriflamme, the real silk banner first of the Abbey of St. Denis, and afterwards of France, was so called because it was a flag (flamme) borne on a gilded (or 'gild') staff. See FLAG.

Origen, the most learned and original of the early church fathers, and perhaps the noblest figure amongst them all, was born, probably at Alexandria, in 183 or 189. His full name was Origenes Alexandreus, the son of the Christian martyr Leonidas, who was beheaded according to Severian in 202. 'Origen was great even from his cradle,' says Jerome. In the early years when he was instructed by his father, Eusebius tells us, 'the simple and easy meanings of the sacred Scriptures were not enough for him, but he sought something deeper, and Leonidas would often bend over his son's head and say aloud 'which the Spirit of God had made His temple.' In the catechetical school of Clement he formed the friendship of Alexander, afterwards Bishop of Jerusalem. He encouraged his father to martyrdom, and his purpose of joining him in this was only frustrated by the terrors of the artifice of the Father, who concealed all his clothes. After his father's death he supported his mother and six brothers by teaching 'grammar,' and from his eighteenth year he acted, with the consent of his bishop Demetrius, as master of the catechetical school. A collection of classical books which he had bought or copied out for himself he sold for a sum which yielded him four obols (or about £d.) a day, which sufficed for his simple wants for many years. According to Eusebius he went so far in his asceticism as to mutilate himself, following a literal interpretation of Matthew, xix. 12, but Jerome, his biographer, doubts this. His intercourse with heretics and educated heathens led him to devote himself to more thorough study of Plato, the later Platonists and Pythagoreans, and the Stoics, under the guidance of the Neoplatonist Ammonius Saccas. In Egypt and Alexandria he taught for twenty-eight years (204-222), composed some philosophic treatises, and commenced his great works of textual and exegetical criticism. The labours of those years were interrupted by journeys to Rome, Antioch, and other places. During a visit to Palestine in 210 the bishops Alexander of Jerusalem and Theophilus of Caesarea had employed him to deliver public lectures in the churches, and on a later occasion in 230 had consecrated him as a presbyter without referring to his own bishop. A synod held at Alexandria under Demetrius forbade him to teach in that city, and a second Alexandrian synod (consisting of bishops only) deprived him of the office of presbyter. The churches of Palestine, Phoenicia, Arabia, and Achaia declined, however, to concur in this sentence. Origen then settled at Caesarea in Palestine, which was his chief home for thirty years. He there founded a school which afforded him the most freedom of teaching, and during this period he was instrumental in bringing in literature, philosophy, and theology. Among their number were Gregory Thaumaturgus and Firmilian of the Cappadocian Caesarea. In the latter city Origen took refuge for two years during the Maximin persecution. In the latter twenty years of his life he was mostly occupied with his other labours. In the Decian persecution he was arrested at Tyre and cruelly tortured. He died there in 253 or 254.

Origen was a most voluminous writer. 'Which of us,' asks Jerome, 'can read all that he has written? Yet the statements of Epiphanius that his works numbered 6000 is doubtless exaggerated. His exegetical writings extended over nearly the whole of the Old and New Testaments, and included Scholia (short notes), Homilies, and Commentaries. Of the Homilies only a small part has been preserved in the original, much, however, in the Latin translations by Rufinus and by Jerome; but unfortunately these cannot be relied upon, for the translators thought fit to modify and tamper with them. Of the Commentaries a number of books on Matthew and on John are extant in Greek, the Commentary on Revelation is the greatest product of his speculative theology. Origen's gigantic Hexapla, the real foundation of the textual criticism of the Scriptures, was too large to be preserved entire. The remains of its text of the Septuagint were collected by Bern. de Montfaucon (2 vols. fol. Paris, 1713) and by Did. Field (2 vols. fol. London, 1836). This text is against Celsus (q.v.), written in his old age, are preserved entire in the original Greek. This, the greatest of early Christian apologists, effectively appeals
to the Christian life as the most convincing proof of the Christian faith. The speculative theology of Origen is presented in his four books Peri Archon, extant as a whole only in the somewhat garbled Latin translation of Rufinus. It is a bold attempt to evolve from the church's rule of faith, with the help of Scripture and reason, a science of Christian faith. Two books On the Resurrection and ten books of Stromata (in which he proved all the Christian dogmas by quotations from the philosophers) are lost. The eclectic philosophies of Greek, Roman, and Jewish writers in the solutions of the problems of the spirit within might be realized. The idea of the process of all the truths from God, their fall, the redemption, and return to God lies at the foundation of the whole development of the world, as the centre of which is the incarnation of the Logos. The spirit of man is the union of divine forces with humanity. Origen's system is an elaborate web, of which Greek metaphysics is the warp, the gospel history the woof. All that was true in Greek philosophy Origen held to in general retaining the name of the Logos, who in Christianity alone is fully and expressly manifested. The proper source of the knowledge of the Christian faith is the Word of God (i.e. the Scriptures). A living faith in those truths of Scripture which have been handed down as fundamental by the church's succession of bishops is itself sufficient for salvation. Beyond such 'unreasoning faith' there is the 'knowledge' or 'wisdom' which rises to the free love of God, and leaves behind it the historical contents of the church's teaching, which have served to it as the moral and intellectual foundations of its religious life, and which is the spiritual faith to the vision of God and likeness to Him. It is by entering more deeply into the successive senses of Scripture that this process is carried out. Scripture admits of a threefold interpretation, in correspondence to three degrees of faith. The 'bodily' (literal or historical) sense is always to be retained, except where it is unworthy of God or contradictory to reason; for God has intended such passages to be 'stumbling-blocks,' suggesting the necessity of seeking a deeper meaning. The ψυχική (or ethical signification) is next; and beyond it is the pneumatic (allegorical or mystical) sense. Unhappily for the memory of Origen, his name was chiefly remembered in connection with the most erroneous part of his work. His fanciful method of interpretation was perpetuated alike in the east and west, and the fruits of his gigantic labours were appropriated by orthodox theologians, who branded him as a heretic, and doubted of his salvation. Long after his death malignant falsehoods were heaped upon his name by unscrupulous enemies of orthodoxy. It was not merely the heresy of maintaining the ultimate origin of all evil in the Supersensible Being, but even heresy respecting the nature of Christ was triumphantly discovered in his writings. Yet, heterodox though he was, not one amongst those honoured by the church as the saints of the Catholic Church in their elevation of character. 'His whole life,' says Bishop Westcott, 'from first to last was fashioned on the same type. It was, according to his own grand ideal, 'one unbroken prayer,' one ceaseless effort after close fellowship with the Unseen and the Eternal. No distractions diverted him from the pursuit of divine wisdom. No persecution checked for more than the briefest space the energy of his efforts. He endured a double martyrdom: perils and suffering from the heathen, redactions and wrongs from Christians; and the retrospect of what he had borne only stirred within him a humbler sense of his shortcomings.'

There is as yet no complete critical edition of Origen's works; the best apology for this is that of the uncle of the great Origen, a nephew, in 1883 and 1884, accompanied by a reprint of Lommatzsch (25 vols. Berlin, 1831–48), and by Migne, Patr. Cur. Comp., ser. Gr., vols. xi., xvii. The Prolegomena to a critical edition by Dr Ph. P. Justinian of the work against Celsus appeared in 1890. The work of P. D. Huet, Origenia in sacros Scripturas Commentaria quaequeque Graece repertae potissimum (2 vols. Rotterdam, 1686), was the foundation of the critical study of Origen. For an account of his theological opinions and the great controversies that these originated, see the works on church history by Baun, Neander, Dörner, Böhning, Schaff, and E. de Presseisen; H. M. W. Hitzig, Der Gekrönte Christus in den Geschichten der Grieichischen Kirche bis auf Origenes (Halle, 1869); Käsemann, Die Lehre vom Heiligen Geist (1847); and the following special books: Thomasius, Origenes (Nürnberg, 1839); Mochtar, Propriete de religie (Antwerp, 1843); H. Fleische, Origenes, eine Darstellung seines Lebens und seiner Lehre (2 vols. Bonn, 1841–46). See also Joly, Etudes sur l'Origine (Dijon, 1880); Breppel, Origine (Paris, 1868); J. D. F. Overweg, Origene (Leiden, 1886); as also Harnack's Dogmenenziehung G. ed. 1883) and Farrar's Lives of the Fathers (1885).

**Original Sin.** See Sin.

**Orihuela** (the Arrivelch of the Moors), a town in the Spanish province of Alicante, on the Segura, 38 miles N. of Cartagena. Situated in a plain of great beauty and fertility, it offers an eastern aspect, with its plateaux, its riverbeds, and a cathedral, a college, and manufactures of silk, linen, hats, &c. Pop. 20,929.

**Orinoco.** one of the great rivers of South America, has its origin on the slopes of the Sierra Puruna, in the extreme south-east of Venezuela; its exact sources were only discovered in 1886 by M. Charles-Edouard Geiger. It is 1,047 miles long, and 23 miles wide at its mouth. It is navigable from the mouth for 67° W. long. A little below Esmeralda (65° 50' W. long.) it divides and sends off to the south an arm, the Casiquiare, which, after a course of 180 miles, joins another, the Rio Negro, a tributary of the Amazon. The other branch, reaching Chiribiquete (4° 10' long. and 4° 2' N. lat.) is met by the strong current of the Guaviare; the united stream then turns due north, and, after passing over the magnificent cataracts of Maypures and Atures (gloomily described by Humboldt), and picking up the Meta on the left, meets the Aparu, which likewise strikes it from the left. Below the confluence with the Aparu the Orinoco turns east and traverses the llanos of Venezuela, its waters, with an average breadth of 4 miles, being augmented from the right by the Cariru and the Caroni. About 120 miles from the Atlantic, into which it rolls its milky-white flood, its delta (5,000 sq. m.) begins. Of the numerous mouths which reach the ocean over 165 miles of coast-line only seven are navigable. The waterway principally used by oceangoing vessels is that navigable up to Ciudad Bolivar (Angostura), a distance of 240 miles, is the Boca de Navios, varying in width from 3½ to 23 miles. The total length of the river is some 1,550 miles, of which 900, up to the cataracts of Atures, are navigable by the usual vessels. About 1,700 miles above the cataracts of Maypures: area of drainage basin, 368,600 sq. m. Most of the larger affluents are also navigable for considerable distances, the
ORIOLE

Meta, for instance, to within 60 miles of Bogotá, the capital of Colombia. As a rule the river floods the districts adjoining its banks from May to January, the country under water sometimes remaining for months.

See A. von Humboldt and Bonpland, Voyage au Continent, vol. ii; Sir Robert Schomburgk, Travels in Guiana (1840); Michelena y Rojas, Exploration Oficial (Brussels, 1867); and Chaffron, Voyage Rendu de Paris Geog. Soc. (1887).

**Oriole**, a genus (Oriolus) and family (Oriolidae) of Passerine birds, confined entirely to the Old World, and characteristic of the Oriental and Ethiopian regions. The members of the family are generally of a bright yellow or golden colour, which is well set off by the black of the wing. Twenty-four species are enumerated under the genus. The best known is the Golden Oriole (O. galbula). The adult male is about 9 inches long. Its general colour is a rich golden yellow; the bill is dull orange; the eye-streak reaches from its base to the eye, the iris is blood-red; the wings are black marked where and there with yellow, and a patch of yellow forms a conspicuous wing-spot; the two middle feathers of the tail are black, indistinctly tipped with yellow, the base, the very tips yellow, the base half of the others black, the other half yellow; legs, feet, and claws dark brown. The female is less yellow than the male, and the under parts streaked with gray. This bird is somewhat rare in England, but it is an annual spring migrant to Cornwall and the Scilly Isles, and it has been found nesting in the south-eastern counties. In Scotland, especially in the southern districts, it has been reported several times; in Ireland it is more rare. In central and southern Europe it is common in summer in certain localities; it is abundant in Persia, and ranges eastwards through central Asia as far as to Irkutsk. It winters in South Africa, where it is found at the Cape, Danannar, Natal, and Madagascar. In habit it is an unobtrusive bird, fond of the shade of woods, groves, and small ravines, and, although generally accounted very shy, it may be found building its nest in avenues in towns. Its food consists of insects and their larvae, especially green caterpillars, and fruits such as currants, cherries, and mulberries. The song of the male is short, loud, clear, and flute-like; he has also a mewing call-note, and a harsh alarum-note. The nest is unlike any other European birds'; it is placed in, and suspended from, a fork in a horizontal branch, sometimes of an oak, usually of a pine, in a shady grove or thick wood, and is made of bark, wool, vessels, leaves, grass, eggs number four or five, and are of a glossey, white colour, blotched with reddish purple. Other orioles are distinguished by having black on the head and neck. *O. kundoo* partly replaces the golden oriole in Turkestan, and extends eastwards to India. *O. cuvieri* found in Africa between the Senegal and the equator, and *O. notatus*, found throughout south tropical Africa, have the lesser wing-coverts yellow, not black as in the European and Indian birds. The birds called 'Orioles' in the United States belong to an entirely different family, the Icteridae. See BALTIMORE BIRD.

**Orion**, in Greek Mythology, an unusually handsome giant and hunter, the son of Hyrieus of Nemea, and by the Nereid Callisto. At Chios he was slain by Merope, daughter of Omopion, but for an attempted outrage upon the maiden his eyes were put out by Dionysus. Orion recovered his sight by exposing his eyeballs to the rays of the rising sun, and afterwards hunted in company with Artemis. The goddess, being unable to bear the constant manner of his desire, sent the blinding out of his eyes. The story of the death and fall of Orion are differently related. Some make Artemis slay him with an arrow, because Eos, enamoured of his beauty, had carried him off to Ortygia, and thereby offended the gods. Others say that Artemis, virgin-goddess though she was, cherished an affection for him that enraged her brother Apollo. One day pointing out to her at sea a black object floating in the water, he told her that he did not believe she could hit it. She took aim and hit the mark, which was the head of her lover swimming in the sea. A third myth makes him find his death from the biting of a snake, and Priam of Salamis gave the men a Helen, to make him to life, but was slain by a bolt from Zeus. After his death Orion was placed with his hound among the stars, where to this day the most splendid of the constellations bears his name.

**Orissa**, an ancient kingdom of India, the authentic history of which goes back for probably more than one thousand years, extended from Bengal to the Bay of Bengal. This province is the extreme south-west portion of Bengal; on the E. it has the Bay of Bengal, and on the W. the Central Provinces. Orissa was long a Buddhist stronghold; in 474 a new dynasty made it Brahmanical, and introduced the worship of Siva; in 1132 this was replaced by Vishnuism and another dynasty. It ceased to be an independent state in 1568, being conquered and made an outlying province of the empire of the Great Mogul. Its next masters were the Mahrattas, who seized it in 1742; but they were forced to surrender it to the English in 1803. At the present time Orissa is divided between the British commissionership of Orissa and the tributary states, and is accounted part of Benga1 Presidency. The commissionership has an area of 9,933 sq. m., and a pop. of (1891) 3,789,799; the tributary states, a hilly country with dense jungle, and the interior plateau, has an area of 14,887 sq. m. and a population of 1,696,710. All this region was visited by severe famine in 1865-69. The principal river is the Mahanadi, and the chief towns Cuttack, Balsor, and Purl (Juggernaut, q.v.). The whole district is sacred ground to the Hindus; evidences of the worship of Siva and Vishnu meet the eye at every turn. Great festivities are held in honour of this latter god and of his image called Juggernaut (q.v.). The most interesting of the aboriginal races are the Kandhs, who number 250,000, besides close upon 150,000 in the Central Provinces. Amongst these people agriculture and the war are the only employments, the menial offices of village life being performed by a subject, almost slave race. They pay profound reverence to the earth-god, and their offerings are directed to his favour, until the practice was suppressed by the British (1837-50). The tribal government is strictly patriarchal. The tribesmen were summoned to arms by messengers bearing an arrow, who sped from clan to clan, like the bearers of the sacred torch in Scotland and former in the Orisses. A great irrigation of a large portion of Orissa is provided for by an extensive and costly system of canals, taken over by the government in 1868.
ORIZABA

—See 'An Account of the Religion of the Khonds in Oriza,' in Trans. Asiatic Soc. (1851); Campbell's Personal Narrative of Service amongst the Wild Tribes of Khondistan (1860), Nos. IX., XI., XV., and XX.; and Oriessa, by W. W. Hunter (1872).

ORIZABA, capital of the Mexican state of Vera Cruz, 82 miles WSW. of Vera Cruz City, and 181 ESE. of Mexico, lies in a fertile garden country, 4030 feet above the sea, and contains an extensive cotton-factory, paper-manufactory, and railway-shops. Pop. 12,900.—The volcano of Orizaba, 25 miles to the north, is a noble pyramid rising to an elevation of 17,576 feet, or, according to Heilprin's measurements (1890), 18,205 feet. Its last severe eruption was in 1366.

Orkney Islands, a group of ninety Scotch islands, islets, and skerries, of which only twenty-eight are inhabited, and which have an aggregate area of 376 sq. m., the largest being Pomena or Mainland (207 sq. m.), Hoy (53), Sanday (260), Westray, South Ronaldsay, Rousay, Streymay, Eday, Shapinsay, Burray, Flotta, &c. They extend for thirty miles east and west, and are separated from Caithness by the Pentland Firth, 65 miles wide at the narrowest. With the exception only of Hoy (q.v.), which has fine cliffs, and in the Ward Hill attains 1564 feet, the scenery is generally treeless,岛s being occupied by cultivated land, fresh-water lochs. The prevailing formation is the Old Red Sandstone, with a small granite district near Stromness; and the soil is mostly shallow, incumbent on peat or moss. The mean annual temperature is 47°, the rainfall 343 inches. The area under cultivation is more than doubled since 1850, but is still less than one-half of the total area. The live-stock during the same period has trebled. The holdings are small—161 acres on an average—and agriculture and fishing are the principal industries. Kirkwall and Stromness, the only towns of the present, have been occupied since 1850, and the standing-stones of Stennis and the tumulus of Maeshowe. Orkney unites with Shetland to return one member to parliament, but it was discovered therefrom as a county by the Local Government (Scotland) Act, 1889, (pop. 1891) 24,445; (1861) 32,395; (1891) 30,453. The Orkneys (Ptolemy's Orceades) were gradually wrested by Norse rovers from their Pictish inhabitants; and in 875 Harold Haarfager conquered both them and the Hebrides. They continued subject to the Scandinavian crown, and the earldom of Orkney was revived and afterwards under the Earls of Angus and Stratheren and the Sinclairs—till in 1468 they were given to James III. of Scotland as a security for the dowry of his wife, Margaret of Denmark. They were never redeemed from this pledge; and in 1500, on James VI.'s marriage with the Danish princess Anne, Denmark formally assigned all claims to the sovereignty of the Orkneys. The present landed proprietors are chiefly of Scotch descent, the islanders generally of mixed Scandinavian and Scotch origin.

SOUTH AFRICA, and Shetland (1883); and Wallace's Description of the Isles of Orkney (new ed. 1884). For map, see Shetland.

Orleans, a city of France, the capital now of the department of Loiret, and formerly of the old province of Orléanais, which comprised the best part of the present departments of Loiret, of Loiret, of Loir-et-Cher, with portions of four others. It stands in a fertile plain on the right bank of the Loire, here crossed by a nine-arched bridge (1760), 364 yards long, and by rail is 75 miles SSW. of Paris. (Orleans) is the capital of Orleans, covering nearly 150 sq. m., and planted with oaks and other valuable trees. The walls and gates have given place since 1830 to handsome boulevards, but the town as a whole wears a lifeless appearance, and its domestic architecture has much more interest than any of the public edifices. These include the cathedral, destroyed by the Huguenots in 1567, and rebuilt from 1601 onwards by Henry IV. and his son Louis XIII. The 15th century Musée (till 1853 the hôtel-de-ville). Note-worthy are the house of Agnes Sorel, Diane de Poitiers, and Joan of Arc, of whom there are three statues—the bronze equestrian one inaugurated in 1855. The commerce is far more important than the industry, in which the public gardening, Orleans possessing unusual transit facilities by road and railway, river and canal. Pop. (1872) 48,976; (1891) 61,073. The Celtic Genabham, where in 52 B.C. the great Gallic rising broke out against Julius Cesar, Orleans afterwards (about 272 A.D.) was renamed Civitas Aurelianii, of which the present name is only a corruption. It was besieged by Attila (q.v.) in 451; passed into the hands of the Franks; and was twice plundered by the Northmen (853 and 865). In 1428-29 it was besieged by the English under the Duke of Bedford, but was delivered by Joan of Arc (q.v.), called therefore the Maid of Orleans. Denoix (q.v.) was known as the Bastard of Orleans. The town suffered much in the wars of the Huguenots (q.v.); and in the Franco-German war it again figured prominently, being taken by the French in 1792. Orleans was annexed by France in 1809, 1814, and 1859, and then the headquarters of the great Army of the Loire until its crushing defeat by Prince Frederick-Charles (December 3-5). Orleans was the death-place of the Earl of Salisbury (1459), of Francis II., Mary Stewart's husband (1560), and of the Duke of Guise (1563). See its history by Binbenet (3 vols. Orleans, 1884-87).

Orleans, Dukes of. This title has belonged to three distinct dynasties of French princes of the blood. The title was first given in 1392 by Charles VI. to his dissolute brother Louis (1371-1407), who became regent on the king's madness, and was murdered in the streets of Paris at the instigation of the Duke of Burgundy in revenge for his father's death (see Jarry's Louis de France, 1890). His successor was his son Charles (1391-1465), the poet. Charles's son Louis succeeded to the throne in 1465, and in 1477, when the States-General of Orleans merged in the crown. It was revived in 1562, when Louis XIII. created his ambitious and intriguing brother, Joan Baptiste Gaston (1605-60), Duke of Orleans and Chartres and Count of Blois. He died without male issue, whereupon Louis XIV. took the title in 1693. But one revenant to the title in 1725, Louis-Philippe (1640-1701), the husband of Henrietta, sister of Charles II., and, after her death, of the Princess Charlotte Elizabeth of Bavaria. His daughters married Charles II. of Spain, Victor Amadeus II. of Savoy, and Prince Charles of Lorraine; his son was the regent and de facto, Louis-Philippe (1674-1725), and his great-grandson was the notorious Egalité, Louis-Pierre Joseph (1747-93). Egalité's son, Louis-Philippe (1773-1850), bore the title during his exile, and until he became king of the French in 1830. His daughter (1810-42) took the title; but it was not borne by his son, the Comte de Paris (1838-94), who in 1883 became head of the French Bourbons, his son, Louis Philippe Robert (born 1809; travelled in Asia, 1860-95; married an Austrian princess, 1890), assuming the title as a Bourbon for the Orientalist party, see BOURBON, FRANCE.

Charles, Duke of Orleans, commonly called Charles d'Orleans, was the eldest son of Louis, Duke of Orleans, and of the high-spirited Valentina Visconti, sister of the Emperor Albert, married in 1406 his cousin Isabella, the widow of Richard II. of England, who brought him scarcely her good-will, but an ample dowry of half a million francs. Three years later she died, leaving him a
daughter. He took his share in the intestine struggles of the time, in alliance with the infamous Bernard d'Armagnak, and did his best to avenge on the Duke of Burgundy his father's murder. He commanded at Agincourt (October 1415), and there, or shortly after, was taken prisoner and held captive by England over a quarter of a century in easy imprisonment at Windsor, Pontefract, Ampthill, Wingfield in Suffolk, and the Tower. In his enforced leisure he hunted, hawked, admired the English ladies, and amused himself with turning some hand to French ballads and rondels, which, conventional and shadow as they are, are easy and graceful in versification, and informed with a musical and tender melancholy that has a singular charm for the reader. His long captivity had made him a martyr to the eyes of Frenchmen—it was one of Joan of Arc's declared intentions to deliver the captive duke, who, she assured her judges, was beloved of God. His imprisonment became even more irksome to him, but he was at length ransomed in 1440 through the good offices of Philip the Good of Burgundy, son of his father's murderer, and became on his marriage to Mary of Cleves. But it was soon discovered that there was nothing of the heroic in his temper or capacity, and he quickly sank again into political insignificance. The last third of his life he spent mainly in great dignity and state at his seat at Blois, where he maintained a kind of literary academy which was visited by all the elegant poets of that rhyming age. His latest act was a vain attempt to defend the Duke of Brittany from the grasping hand of Louis XI. He died at Amboise, 4th January 1465. His son became Louis XII. of France.

The best edition of the poems of Charles d'Orléans is that of C. d'Héricault in the 'Nouvelle Collection Jannet' (2 vols. Paris, 1874). The Debate between the Herolds of France and England is assigned to him by Mr Henry Fyne, its translator and editor; but M. Paul Meyer, in his edition of the poem, has declared against this authorship. See Beaulot's Étude (1861); and R. L. Stevenson, in Familiar Studies of Men and Books (1882).

JEAN BAPTISTE GASTON, DUKE OF ORLEANS, was the third son of King Henry IV., was born in 1668, and was granted the title in 1626 on his marriage with Marie of Bourbon, Duchess of Montpensier. He died in 1686, and his daughter, 'La Grande Mademoiselle,' he triumphed France with incessant and bloody but fruitless intrigues against Richelieu, and but for his royal birth would have lost his head like Montmorency, Cinq-Mars, and De Thou. The validity of his marriage with Margaret of Lorrairie was made a perpetual by the king, and after his long dispute among jurists and theologians. After Richelieu's death a reconciliation was effected between him and the king, and he was appointed lieutenant-general of the kingdom during the minority of Louis XIV. The duke, finding himself impotent in the hands of Mazarin, placed himself at the head of the Fronde, but with his usual selflessness soon threw over his friends and made terms again with the court. After Mazarin's final triumph he was confined to his castle of Blois, where he died, 21st February 1669, leaving three daughters by his second marriage. See R. Mâkovetz.

PHILIPPE, DUKE OF ORLEANS, regent of France during the minority of Louis XV., was the son of the first Duke Philippe, and the grandson of King Louis XIII. He was born on 4th June 1640, possessed excellent talents, and acquired knowledge with readiness, but his tutor, Dubois, afterwards cardinal, early demoralised him by ministering to his passions, and, hardly yet grown up, he gave himself up to debauchery. The king commanded him at Lorrairie, and gave de Choisy his daughter by M. de Montespan. The young prince now began to alarm the court by an unsuspected capacity for war, showed courage at Steen- kirk and Neerwinden, and commanded with success in Italy and Spain. But his presence in Madrid after his victories was disliked both by Philip V. and by Louis XIV., and he was banished over the Pyrenees. He lived in complete exile from the court, spending his time by turns in profugacy, the practice of the fine arts, and the study of chemistry. Louis, having legitimised his sons the Duke of Maine and the Count of Toulouse, appointed the Duke of Orleans president of the regency council; he was regent, giving the guardianship of his grandson and heir and the command of the household troops to the Duke of Maine; but this arrangement was set aside at his death (1715), and the Duke of Orleans became sole regent. He was popular, and his first measures increased his popularity; but the financial affairs of the kingdom were perplexing, and the regent's adoption of the schemes of Law led to disastrous results. He favoured an English and anti-Spanish alliance, and Anglomania, or a craze for everything English, was one of the features of his régime. The English, with Philip'sрабаттах, Mary of Cleves, formed, in 1717, was joined next year by the emperor, and this quadruple alliance succeeded in effecting the downfall of Alberoni and his wildly-ambitious schemes. At the instance of Lord Stair, the English ambassador, he expelled the Pretender from France. He was thus engaged in the affairs of Paris meddling with financial or political affairs, and declared the legitimised sons of Louis XIV. incapable of succeeding to the throne. Dubois now became prime-minister, and ere long Archbishop of Cambrai and cardinal. To appease the crowds he sacrificed the states and the legislature, and, in the parliment in 1722 to recognise the bull Unigenitus. Yet he was faithful to his trust, and the indolent young prince on his coming of age (1723) rewarded him by retaining him in power. But Dubois died in the August of the same year, and the French king and later, Philippe's France gave way under the burden of his debaucheries, 22 December 1723. See the works by Pissens (5 vols. 1749) and Capefigue (2 vols. 1838).

LOUIS-PHILIPPE-JOSEPH, DUKE OF ORLEANS, the famous French poet, was born April 13, 1747, and succeeded to the title on his father's death in 1785, having been Duke of Chartres since 1752. He possessed good abilities, but early fell into a course of debauchery which he never quitted till the end of his career. In 1769 he married the heiress of the Duke of Penthievre, and used his immense wealth to advance his political interest. But he was looked upon coldly at court, and still more so after the accession of Louis XVI. (1774), who abhorred his morals, while Marie Antoinette grudged him his wealth and independent position and hated the criticisms of the ring of witty reprobates who clustered round him. He fough'd at Ushant, but was prevented from further service and promotion to the rank of admiral by the jealousy of the court. He visited London frequently, became an intimate friend of the dissipated young Prince of Wales, afterwards inglorious as George IV., and infected young France with Anglomania in the form of horse-racing and hard drinking. He made himself widely popular by profuse charity and by flinging open to the poor the splendid gardens of the Palais Royal. In the 'Lettre de justice de November 1783,' he was reproved by the king, and was sent by a lettre-de-cachet to his château of Villers-Cotterets. As the States-general drew near he raised his wealth in disseminating throughout France books and newspapers by Selves and other advocate of liberal ideas, and had himself put up in as many as five buildings, but was elected in but three, Crepy-le-Valois, Villers-Cotterets, and
Paris. In October (1788) he pronounced his Débâlérations, written by Luclos, to the effect that the tiers état was the nation, and in June 1789 he led the forty-seven nobles who seceded from the Constituent Assembly when it tried to impeach Louis XVI, guided by Adrien Duport and others, he dreamed of some day becoming constitutional king of France, or at least regent, but it is no less certain that the indolent debauchee was to a great extent the mere dupe of a party, and at no time the deep design of which was believed to be at court. There the blame of everything was cast upon his head, even of such great outbursts of the revolutionary fever as the fall of the Bastille and the march of the women on Versailles. Orleans gradually lost influence, and felt so hopeless of the Revolution that he would willingly have gone to America had his mistress, the abandoned Comtesse de Buffon, consented to accompany him. From October 1789 to July 1790 he was absent in England on a mission, and after his return he took a smaller share in political matters than before, while his efforts to come to an understanding with the court were still met with repulse. In September 1792 all hereditary titles being swept away, he demanded a new name from the Paris electors, and adopted that of Philippe Égalité, suggested by Madame du Barry's office. This deputation was not permitted to go to Paris to the Convention, and gave his vote of death for the king, which sent a shudder to the heart even of the Mountain. His eldest son, the Duke of Chartres, afterwards King Louis-Philippe, was a brave and active officer on the staff of Dumerouz, and rode with his chief into the Austrian camp. Égalité was at once arrested with all the Bourbons still in France, and, after six months' duration at Marseilles, was brought to Paris for trial. He was found guilty of royalism and conspiracy, and guillotined the same day, 6th November, with three other deputies. Striking his lips and all the high courage of the old régime.

See Baschet's Histoire de Philippe Égalité, the elaborate work by Tournois (2 vols. 1840-43), and Mrs Elliot's Journal (1850).

Orloff, a Russian family that first rose to eminence during the reign of Peter III., when one of its members (1724–83) was appointed with due notice of the Grand-duchess Catharine, afterwards the Empress Catharine II., and succeeded Poniatowski as her favourite. It was this man who planned the murder of Peter III., and his brother Alexis (1737–1809) who committed the deed in 1796. Both brothers were men of gigantic stature and herculean strength. The family of the Counts Bobrinski resulted from Gregory's intercourse with the empress. The legitimate line of Orloff soon became extinct; but Feodor, a brother of Gregory and Alexis, left four illegitimate sons, one of whom, Alexis (1787–1861), signalised himself during the French wars and in Turkey, negotiated the treaties of Adrianople (1829) and Unkarr-Skilesi (1833), and represented Russia at the London conference of 1832 on the affairs of Belgium and Holland. In 1844 he was placed at the head of the secret police, and stood high in favour with the Emperor Nicholas, who employed him in the negotiations with Austria previous to the Crimean war. In 1856 he sat in the congress of Paris as the representative of Russia, and on his return was made president of the grand committee, and to the emperor appointed the president of the committee for the franchise of the serfs.—For the Orloff diamond, see DIAMOND.

Ormer. See HALIOTIS.

Ormerod, Eleanor A., entomologist, the daughter of George Ormerod (1785–1873), the historian of Cheshire. She commenced her contributions to the science of entomology in 1898 in connection with the Bethnal Green Museum. In 1880 she edited the Cobham Journals, being the meteorological and other observations made during forty years by Miss C. Molesworth, and during her long term of office, the accumulation of 75,000 observations. In 1882 Miss Ormerod was appointed consulting entomologist of the Royal Agricultural Society, and shortly afterwards became special lecturer on economic entomology at the Royal Agricultural College, Cirencester. Her several Manuals of Insects (1879) and Entomology and Methods of Insect Life (1884) are the most generally interesting of her works, which consist principally of papers on different injurious insects of South Africa and Australia, as well as of England. She died 19th July 1901.

Ornolu, a name sometimes given to brass of a golden yellow colour.

Ormonde, an old name for what became afterwards East Munster, comprising Tipperary.

Ormonde, James Butler, Duke of, was the first of the ancient Anglo-Irish family of Butler on whom the ducal title was conferred. The family was of illustrious antiquity. In the beginning of the 13th century Theobald Butler, from whom the Duke of Ormonde was descended, held the hereditary office of cupbearer in Ireland. It was he who first assumed the title, and he was the first to use the arms of the House of Ormonde.

The subject of the present article was born in London in 1610. His father, the son of the celebrated Walter, Earl of Ormonde, was drowned in crossing the Channel; and the old earl having incurred the displeasure of the king, James I., and being thrown into prison in a dungeon in the Tower, was beheaded. In the earl's death became, as Viscount Thurles, the heir of the title, was taken possession of as a royal ward, and placed under the guardianship of the Archbishop of Canterbury. On the restoration of his grandfather to liberty, he also was released; and in his twenteth year he married his cousin, Lady Elizabeth Preston, and in 1632 succeeded, upon his grandfather's death, to the earldom and estates of Ormonde. During the Strafford administration in Ireland Ormonde distinguished himself so much that on Strafford's recall he recommended him to the king; and in the reign of Charles I., Ormonde was appointed to the chief command of the army. During the troubled times which followed he conducted himself with undoubted ability, although, as a necessary consequence of the numberless secret divisions and plotings of the time, he was vilified in Ireland, he failed to satisfy any one of the conflicting sections; and when, in 1645, he concluded an armistice, his policy was loudly condemned as well by the friends as by the enemies of the royalist party in England. During the long contest of Charles with the Parliament, Ormonde continued to uphold the royal interest in his Irish government; and when the last crisis of the king's fortunes came, he resigned his Irish command, and retired to France, from which country he again returned to Ireland with the object of restoring the royal authority. After a gallant but unequal struggle, he was, however, compelled, in 1650, to return to France. His services to the royal cause continued unremitting during his exile; and at the Restoration he accompanied Charles II. to his return in 1660, as a reward for his fidelity by the ducal title of Ormonde. His after-life was less eventful, although he twice again returned to the government of Ireland. It was in 1679 that the well-known attempt was made by the notorious Colonel Blood (q.v.) upon the life of Ormonde. At the time of the Restoration festival, he was attacked by Blood and a party of ruffians, and was dragged from his coach with the intention of his being hanged at Tyburn. The attempt drew additional interest from its being
commonly supposed to have been instigated by the profligate Duke of Buckingham, Ormonde's inveterate foe. He escaped uninjured, and lived until the year 1688. As a soldier he exhibited both skill and bravery in command; and as a politician he was singularly upright in a period when there were many opportunities for the trimmer and the charlatan. The letters and other papers are full of deep historical interest. See Carter's Life of Ormonde (1785-96).

James Butler, second Duke of Ormonde, was the grandson of the foregoing. He was born in Limerick town, and at the age of fourteen was sent to France for his education, whence he returned after a few years, and was entered at Christ Church, Oxford. In 1682 he married Anne, daughter of Lord Hyde, afterwards Earl of Rochester. As Earl of Ossory he served in the army against Monmouth, and also held an office in the palace under James II. After his accession to the dukedom by the death of his grandfather in 1688, he took his share in the Revolution, conflict, at first being for moderate measures; but he must have seen the futility of these, for afterwards, at the coronation of William and Mary, he acted as lord high constable. He was present at the battle of the Boyne, at the head of William's light guards. He soon became popular. In 1702 he was placed in command in the expedition against Cadiz; in 1703 he was appointed lord-lieutenant of Ireland, and in 1711 commander-in-chief of the land forces sent against France and Spain. After the accession of George I. Ormonde somehow fell into disgrace with the king, and was impeached in 1715 of high treason, with the result that his estates were attainted, and he was deprived of all his honours. He retired into France, where he attended himself to the Jacobite court, and spent many years in the secret intrigues of the Pretender and his followers. He died abroad in 1746. A collection of letters written by him in the organisation of the abortive attempt by Spain to invade England and Scotland in 1719, and which led to the affair of Glencoe (q.v.), were in 1890 brought to light, in the following years prepared for publication, and in 1896 issued by the Scottish History Society.

Ormskirk, a market-town of Lancashire, 12 miles N.N.E. of Liverpool. It has a grammar-school (1612); a parish church, with embattled tower and spire, and the burial-vault of the Earls of Derby; and manufactories of cordage, iron, silk, cotton, &c. Pop. (1851) 6183; (1861) 6651; (1891) 6938.

Ornithorhynchus, or Duck-mole (also called Duck-billed Platypus, the 'water-mole' of colonials), one of the lowest mammals, found in the rivers of Australia and Tasmania. Along with the Porepine Ant-eater (Echidna, q.v.) and a neighbour genus, the duck-mole is included in the sub-class Prototheria or Ornithodelphia, co-extensive with the order Monotremata. These three genera are of great interest as 'living fossils', retaining the ancient characters of primitive mammals.

The duck-mole, represented by a single species (Ornithorhynchus paradoxus or anatinus), is a flat animal, between a foot and 18 inches in length, not including the broad beaver-like tail, which measures 4-5 inches. The thicke, soft fur is dark-brown above, rusty yellow below. The very short legs have webbed digits in adaptation to the swimming habits, and are also equipped with strong claws, utilised in burrowing. The 'duck-bill' is due to the anterior expansion of the premaxilla and mandibles, is covered with a horny sheath, bears the nostrils far forward, and is provided with curious tactile structures. Behind the 'bill' is a loose, naked, sensitive collar. The eyes are very small, and there are no external ears. Within the mouth true teeth are present only in the earliest stages; their place is taken in the adults by eight horny plates, sharp-edged in front, broadened out behind. The tongue is not extensible. In the young of both sexes a curious perforated spur, associated with a gland, occurs near the heel, but...
this only persists in the males, which are further distinguished in being somewhat larger than their mates. The body temperature is peculiarly low. The voice resembles the crow of a small puppy. No fossil forms are known.

This lofty mammal is essentially aquatic, living in rivers and 'ponds,' swimming and diving admirably. It is lively and active, diving when alarmed, and able to remain several minutes under water. It constructs on the bank elaborate burrows (sometimes 20 to 50 feet in length) with two entrances — one above, the other under water. Like many other defenceless animals, it is most active in the twilight. It grubs in the mud for worms, swarms of water-insects, molluscs, &c., which it can temporarily stow away in cheek-pouches. When frightened or asleep it often rolls itself up, in hedgehog fashion, into a living ball. It appears to resuscitate itself with the water-rat, but is molested by carnivorous marsupials, and is often wantonly, though fortunately not easily, shot. The eggs — for the discredited oviparous habit has been confirmed — are laid in a rough nest within the burrow. The young appear to use their bills in breaking the tough shell. The animals have afishy, oily smell. The flesh is eaten by the omnivorous natives, who are said especially to esteem the young forms.
